The blood pressure was 110 systolic, 70 diastolic.

Examination of the blood disclosed a red-cell count of 3,630,000, with 40 per cent hemoglobin, and a white-cell count of 10,300, with 50 per cent neutrophils, 46 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils and 1 per cent basophils. The specific gravity of the urine varied from 1.008 to 1.028. The urine was negative for albumin, casts and cellular sediment. Two stool cultures were negative for pathogens, and an examination for amebas was negative. An x-ray film of the heart and lungs was noncontributory, and a barium enema showed extinction of the haustral markings with narrowing of the lumen and shortening of the bowel. On proctoscopic examination scattered pin-point, shallow ulcerations with fine hemorrhages were seen.

The serum nonprotein nitrogen was 19 mg., and the total protein 6.3 gm. per 100 cc., and the chloride 104 milliequiv. per liter. A blood Hinton test was negative.

During the patient's hospital stay of two months he was given sulfasuxidine, tincture of belladonna and two transfusions. He improved slowly and gained weight, and his bowel movements decreased to one or two a day.

*Second admission* (two and a half years later) During the interval the patient visited the Out-Patient Department regularly and gained about 20 pounds, although his diet was apparently not adequate in protein. One week before entry, following a cold, he developed slight abdominal swelling, anorexia and vomiting. He also noted swelling of the legs and scrotum. The urine was darker than previously.

On physical examination the abdomen was distended, with a well marked fluid wave. The liver edge was palpable two or three fingerbreadths below

behind the ascending colon. There are some spot films showing this constriction, which is very uncharacteristic, certainly in its shape. It does not simulate primary carcinoma of the colon. In this spot film it is conceivable that a smaller cancer is behind in the tip of the cecum, but I cannot see that in these films. The lateral view gives a better position of the cecum and ascending colon with the narrowed zone. There are many films of the small bowel. At least ten films of the small bowel were given to me. In none of them can I see the actual terminal few inches of the ileum and the actual ileocecal valve. When one looks at the loops of small bowel in the films taken at the time of the first admission and compares the pattern of the arrangement of loops of small bowel, one has the impression that the pattern does change to some degree—not quite so much, however, as it does in the average patient with a normal peritoneal cavity. This loop, for instance, is present in both these films in a similar position. In other words, I have from these films the same impression given in the reports that these loops were not freely movable but were for some reason fixed. The soft-tissue mass described in the report is not too obvious. One can see here the loop of small bowel described as running around the soft-tissue mass. There is one piece of bowel seen on only one film that I cannot explain. It looks as if it were locally dilated. If it is small bowel, it looks as if it were probably terminal ileum, and I think its proximal end was not demonstrated, this may be due to disease. Here, on another film, this might be the same loop. It is not quite so dilated, and it again ends up before it reaches the cecum. At the last examination the cecum had changed little. One still sees the constriction here, which I think is probably in the region of the ileocecal valve. On some of these films a peculiar swelling just distal to the constricted area is apparent.

To summarize the x-ray findings, after discarding the ones I decided were of no significance, I find a lesion in the region of the ileocecal valve, but I am not certain whether it started on the cecal side or on the side of the ileum. I am not certain how it looks because I am not certain I actually see the lesion. If it is in the cecum, I do see it, and it would be a very unusual type of tumor. If it starts in the ileum, I do not believe it is ileitis from the evidence we have here, but it is probably a tumor. There is, however, an outside chance that it is tuberculosis, which also might explain the changes in the peritoneal cavity. I would say first that this was a tumor of the ileocecal valve and secondly, as an outside possibility, tuberculosis. As a matter of fact, I never remember having seen a patient with tuberculosis with massive hemorrhage, but I suppose it can happen.

I looked over all the films of the stomach, and something has been worrying me for a while. The

stomach appears on these films not quite so flexible as the average stomach does when several films are taken. It does not quite fit the shape of a normal stomach. It looks as if it might be infiltrated. From the evidence at hand I do not see any way of making a diagnosis of scirrhus carcinoma of the stomach. Again, I am forced from the evidence at hand to forget about the stomach. I shall not try to go any farther histologically because I am a little uneasy about the actual shape of the lesion.

DR TRACY B. MALLORY: Would you be willing to hazard a guess whether the tumor in the region of the ileocecal valve is benign or malignant?

DR SCHATZKI: If I guess, I do so against my roentgenologic conscience because I am making a pure guess without actually seeing the lesion correctly. Statistically I should say that it is cancer. There are, however, a few things that are a little peculiar and make me think it very well may not be a straightforward cancer. One reason for my statement is the apparent good clinical condition of the patient with a history of twelve months' duration, the second reason is connected with the fact that attacks of partial obstruction lasted over such a long period. Obstruction due to cancer of the ileocecal valve usually persists once it is established. The history in this case might, therefore, be interpreted as consistent with benign tumor. If I wanted to guess further, a common benign tumor in that area would be carcinoid. Yet I do not know that a carcinoid could produce so much bleeding, but I think it could. Am I right about that?

DR MALLORY: Carcinoids almost never ulcerate the mucosa.

DR SCHATZKI: In other words, it will not bleed. The most common benign tumor in the small bowel or in the colon to bleed is an intramural, extramucosal tumor. I do not have any right to make that diagnosis unless I put more stress on the soft-tissue mass than I believe I have a right to from the evidence at hand.

DR ALLEN G. BRAILEY: How do you explain the left-upper-quadrant pain, Dr Schatzki?

DR SCHATZKI: The only possible explanation is that when the patient had pain she had partial obstruction with the hyperactive area of bowel in the left upper quadrant rather than the right. Usually, a patient with ileocecal obstruction has pain on the right side.

#### CLINICAL DIAGNOSES

Diverticulitis and diverticulosis of descending colon, with partial large-bowel obstruction  
Hiatus hernia  
Neoplasm of ascending colon?

#### DR SCHATZKI'S DIAGNOSIS

Tumor of ileocecal valve, possibly carcinoid

high white-cell count there was no obvious evidence of sepsis and the abdominal tap did not disclose peritonitis, at least in the region where the tap was made

I think that it is clear that this patient had disease involving at least three organs of the body. It is difficult, for me at least, to think of one diagnosis to explain all three conditions. I shall probably have to be content with several diagnoses and assume that there may be more than a coincidental relation among them. As you know, there are many extra-intestinal complications of so-called idiopathic chronic ulcerative colitis. Among the rarer ones are nephritis and parenchymal liver disease. Although the odds are perhaps against the coexistence of both these complications in the same patient, there is no reason why this situation should not take place. In one series of patients with ulcerative colitis, nephritis was reported in 13 per cent,<sup>1</sup> and in another, 1 per cent.<sup>2</sup> We do not know the exact nature of the renal lesion. In another series of patients with ulcerative colitis liver disease was recorded in 3 per cent,<sup>3</sup> thus making it a rare complication. There have been a few biopsies and post-mortem examinations of patients with this complication, but there has been no uniformity, as far as I can tell, in the findings. The condition is described as portal cirrhosis, chronic hepatitis and even hypertrophic biliary cirrhosis. In some cases the colitis has been mild, and the liver disease the most disabling condition.

Another possibility is that the patient had amyloidosis, secondary to long-standing chronic ulcerative colitis. This is also a rare complication of ulcerative colitis, but we have had at least 1 case in this hospital. The renal lesion could be explained on this basis. A feature against amyloidosis, but not necessarily ruling it out, is the degree of hematuria at the time of this patient's second admission. Although amyloidosis, if present, commonly involves the liver, the function of this organ is usually well preserved so that jaundice, ascites and laboratory evidence of depressed liver function are not usually recorded. There are, however, occasional exceptions, chiefly in the primary systemic type of amyloid disease. This brings me to the possibility that this patient had a primary type of amyloidosis, with amyloid infiltration of the intestinal wall simulating chronic ulcerative colitis. Diarrhea and intestinal bleeding have been described in systemic amyloidosis but never, so far as I know, a picture so closely resembling idiopathic ulcerative colitis as is seen in this patient. The terminal blood findings in this patient are of some interest. The presence of immature red cells suggests a myelophthisic anemia, with the remaining marrow overactive. Could this have been a response to amyloid infiltration in the marrow? The high white-cell count suggests sepsis, but the location is not clear. Or there could have been a venous thrombosis,

perhaps in the portal system. Although the single diagnosis of amyloidosis is appealing in explaining to us most of the picture, I have decided to reject it as far as the liver is concerned. The reason for this is that amyloidosis rarely causes liver failure, but when it does it is more on a mechanical basis, with squeezing out of the liver cells and obstruction of the bile canaliculi. Early evidence of severe liver damage would be against the diagnosis of amyloidosis of the liver in this patient.

We are left then with the diagnosis of ulcerative colitis, idiopathic type, and liver disease. In view of the persistent evidence of liver-cell damage, I think that I will call it toxic cirrhosis rather than cirrhosis of the portal or biliary types. In fact, the terminal episode may have represented severe, widespread liver necrosis. In regard to the renal lesion, although I think that it could well have been due to amyloidosis, in view of the findings in the urinary sediment at the time of the second admission, I shall put glomerulonephritis ahead of this diagnosis. I shall not try to discuss the possible relation of all three conditions. If my diagnosis is correct, I think that a relation is possible but on a rather hypothetical basis. Finally, it would be very helpful to have had some Congo-red tests on this patient.

DR TRACY B MALLORY Obviously this is an extremely difficult case. Does anyone wish to make an alternative diagnosis?

DR DANIEL S ELLIS I followed this patient, and I might say that, although he had three apparently serious diseases, at no time did he ever have any conception of how sick he was. It is of interest that he was accepted in the National Guard and did three weeks' duty at Camp Edwards within two months of the final and fatal admission. The only way they found out he was sick was that he caught a cold and went on sick call and urinalysis revealed albumin, so they sent him home. He was indignant with the armed forces and the country in general because a strapping fellow like himself should be rejected. The last year of his life was possible because of the availability of human serum albumin. No other diuretics were effective. This boy had no symptoms during this period other than anasarca, which would gradually increase until it became incapacitating. Then he would come to the hospital for a course of 300 gm of albumin and be discharged at the end of a week with a sufficient sense of well-being to go cheerfully back to school for another period.

In answer to Dr Short's question at the time the liver disease was manifested he was icteric. Those who were following him thought that he had chronic ulcerative colitis, that he developed acute hepatitis, and went on to a toxic cirrhosis, and that he probably died of acute nephritis, progressing to subacute or chronic stage.

the right costal margin. There was slight edema of the scrotum and ankles.

Examination of the blood revealed a red-cell count of 3,440,000, with 11.4 gm of hemoglobin, and a white-cell count of 8350, with a normal differential. The specific gravity of the urine was 1.030, with a +++ test for bile, and a +++ test for albumin, the sediment contained innumerable red and white cells and hyaline and granular casts. The alkaline phosphatase was 19.8 units, the thymol turbidity 7.8 units and the thymol flocculation +++. The serum total protein was 6.76 gm per 100 cc, with 3.02 gm of albumin and 3.74 gm of globulin. A cephalin flocculation test was +++ at twenty-four and forty-eight hours, and there was 36 per cent retention of bromsulfalein.

The patient remained in the hospital for about nine weeks, receiving four transfusions and therapy directed toward amelioration of kidney and liver disease. On discharge, however, the bromsulfalein retention was 52 per cent, and the serum albumin 2.98 gm per 100 cc. The urine showed a + test for albumin, with 10 to 15 red cells per high-power field and moderate hyaline and granular casts in the sediment.

*Final admission* (one and a half years later). During the interval the patient re-entered the hospital three times because of return of edema and ascites. His bowel movements had been controlled fairly well, averaging two or three a day. On these admissions he was given concentrated human albumin with satisfactory release of fluid. He also developed some swelling of the breasts during this period. He persistently showed some albuminuria, an increased cephalin and thymol flocculation and an altered albumin-globulin ratio, except following administration of concentrated albumin. About ten days prior to his final readmission he began to have anal pain and later complained of a "gassy" feeling in the stomach, followed by severe and persistent vomiting for four days.

On physical examination he retched occasionally during the interview but did not vomit. The abdomen was distended and flat to percussion throughout. There was pitting edema of the legs.

The blood pressure was 100 systolic, 50 diastolic. Examination of the blood showed 5 gm of hemoglobin and a white-cell count of 60,000, with 97 per cent neutrophils and 3 per cent myelocytes. Severe toxic granulation of the polymorphonuclear leukocytes was present. There was marked hypochromia and polychromatophilia, with 5 to 10 nucleated red cells per 100 nucleated cells. The urine specific gravity was 1.010, a  $\pm$  test for bile was present and there were 2 or 3 hyaline casts per high-power field. The serum nonprotein nitrogen was 103 mg per 100 cc, the carbon dioxide 22 milliequiv and the chloride 88 milliequiv per liter. The total protein was 3.68 gm per 100 cc, with 1.08 gm of

albumin. The prothrombin time was 39 seconds (normal, 16 seconds), and the cephalin flocculation test was +++. A van den Bergh reaction was 3.2 mg per 100 cc direct and 4.3 mg indirect.

Following admission three blood transfusions were administered. An abdominal paracentesis yielded 80 cc of clear, straw-colored fluid, showing 30 cells per cubic millimeter and no organisms on direct smear. The temperature, which was normal on admission, remained about the same. On the fourth day the patient became rather drowsy, and on the following day he became disoriented and died.

#### DIFFERENTIAL DIAGNOSIS

**DR. CHARLES L. SHORT:** At the time of this patient's first admission, at the age of thirteen, the picture certainly was that of chronic ulcerative colitis from the clinical and proctoscopic and x-ray findings. May we see the films?

**DR. JAMES J. McCORT:** X-ray examination of the colon revealed a rigid and shortened large bowel. The haustral markings are scant. In the rectosigmoid region one can see small ulcerations in the wall of the colon. Even after evacuation a normal mucosal pattern is not seen. The changes are consistent with a chronic ulcerative colitis. Examination of the chest made, I believe, before the final admission shows marked elevation of the diaphragm due to the increased intraperitoneal fluid and also a small amount of fluid in the costophrenic sinus. The lungs, so far as we can see, are clear.

**DR. SHORT:** Is there an examination of the small intestine?

**DR. McCORT:** No examination was made. There was no filling of the small bowel at the time the barium enema was performed.

**DR. SHORT:** In this patient's first admission there was no real evidence of the renal or hepatic disease that later made its appearance. Two and a half years later, just before the second admission at the age of fifteen, ascites and edema rather suddenly developed. There is nothing in the record regarding clinical jaundice or whether or not he had increased bilirubin in the blood, but at least he had bile in the urine. Liver-function tests were those indicating severe parenchymal liver disease. In addition, and I believe not accounted for on the basis of liver disease, he had marked albuminuria with casts and large numbers of red and white cells in the urinary sediment. These findings certainly point toward renal disease and fit most closely with glomerulonephritis. The colitis was apparently mild after the patient's discharge, but the evidence of liver and renal disease persisted. At the time of the last admission, at the age of seventeen, the urine showed a low specific gravity on one examination at least and absence of cellular elements in the sediment, and for the first time he developed nitrogen retention. It is interesting that with the

## BOSTON UNIVERSITY SCHOOL OF MEDICINE

1848-1948

Boston University School of Medicine, in celebrating its hundredth anniversary this month, recalls with pride that its original foundation was based on the idea of higher education for women. On November 1, 1848, the Boston Female Medical College, the first of its kind in the United States and probably in the world, began its instruction in medical subjects, three years later it changed its name to New England Female Medical College. The entering wedge had been driven, and the right of women to enter the professions acknowledged.

The Massachusetts Medical Society, a bulwark of conservatism was in opposition. Nevertheless,

many of the professors of the new school were members of the Society and graduates of Harvard. The first woman professor, Dr. Marie E. Zabrzevska, appointed in 1859, became later one of the founders of the New England Hospital for Women and Children.

At first an institution that merely gave instruction in medical subjects, the new college in 1852 inaugurated its complete course leading to the degree of Doctor of Medicine. The first class of four women, graduated in 1854. Many women attended sessions without graduating, some leaving to enter practice without a degree and others to become midwives, nurses or teachers of physiology.

In 1870 the School erected a permanent building on East Concord Street that is still in use as part of Boston University School of Medicine. In 1873 the most important step was taken that the School had yet made: the joining of forces with the infant Boston University and the Massachusetts Homeopathic Medical Society, which had been organized in revolt against the drastic empiricism of "regular" medicine of the day. The School, its original function discharged, became coeducational and homeopathic. During this year, also, an amphitheater was provided that was to serve the classes for the next seventy-five years.

An optional four-year course in addition to the required three years was instituted in 1878, and in 1890 this was made obligatory — a pioneer requirement in America. In 1918, homeopathy having achieved its logical purpose of breaking down a dogma from the past, Boston University School of Medicine became nonsectarian.

The clinical teaching facilities of the School have been impressively increased. The John C. Haynes Memorial for Contagious Diseases was opened in 1909, the Robert Dawson Evans Memorial for Clinical Research and Preventive Medicine in 1911 and the Jennie M. Robinson Maternity Department in 1916. Extensive teaching affiliations have been established with the Boston City Hospital, various state hospitals, the Judge Baker Guidance Center, the James Jackson Putnam Children's Center and St. Margaret's Hospital.

May the future be as rewarding as its diversified past has been to this eminent school of medicine!

DR JACOB LERMAN I saw him on the ward during the second admission and I tried very hard to make one diagnosis fit all the findings, but it was difficult. Of course, we thought that amyloid disease would be the best bet. I do not know why it was omitted from the record but there were three or four Congo-red determinations, and all were within normal range. So we thought that he had three separate diseases: nephritis, ulcerative colitis and toxic cirrhosis.

DR EARLE M. CHAPMAN I likewise saw this patient on the service, and I had a different idea from the previous visiting man who saw the patient. He had dissociated the liver disease and thought it was not related to the ulcerative colitis. I thought of tying them together. I raise the question whether therapy had anything to do with the renal lesion, which Dr Mallory will describe. Was it related to the intensive intravenous therapy with albumin and other things that he received? I would be interested to hear Dr Mallory's comments on the possible etiology of the renal lesion.

DR ELLIS The patient developed the renal damage before he received the albumin.

DR LERMAN I agree. The albumin was given on the second admission, and the renal damage had already been established. He did have sulfadiazine, however. Do you think that may have had any etiologic relation?

DR MALLORY Were any transfusions given before the second admission? Plasma or whole blood?

DR SHORT The record states that he had one.

DR MALLORY One and a half years is too long an interval for serum hepatitis.

DR LERMAN There was a two-and-a-half-year interval between the first and the second entry.

DR ELLIS He had none during that time.

#### CLINICAL DIAGNOSES

Cirrhosis of liver, toxic  
Cholemia

#### DR SHORT'S DIAGNOSES

Chronic ulcerative colitis  
Toxic cirrhosis of liver  
Glomerulonephritis

#### ANATOMICAL DIAGNOSES

*Chronic ulcerative colitis, severe*  
*Cirrhosis of liver, toxic type*  
*Acute glomerulonephritis*  
Hemorrhage from esophageal varices  
Anasarca  
Gynecomastia

#### PATHOLOGICAL DISCUSSION

DR MALLORY Post-mortem examination confirmed the three separate lesions: chronic ulcerative colitis, a severe degree of cirrhosis of the liver, of the grossly nodular, postatrophic type that here we call toxic cirrhosis, and acute glomerulonephritis. The immediate cause of death was hemorrhage from ruptured esophageal varices. From there on I think one must pass into the realm of speculation. A large proportion of patients with severe ulcerative colitis develop fatty livers before death, and on two occasions I can remember having seen the lesion progress into a mild degree of fatty cirrhosis of the finely granular type, which we usually associate with a history of chronic alcoholism. This probably was not that type of cirrhosis. I do not know any direct way of connecting the liver and the renal disease. There is enough element of sepsis associated with ulcerative colitis to make it not unreasonable that an occasional case should develop glomerulonephritis, but I think we have to consider that a separate complication and I do not see how we can tie the liver and the kidney lesions together with one mechanism.

DR ALFRED KRANES Is there anything to account for the extreme leukocytosis?

DR MALLORY The bone marrow showed only very marked diffuse hyperplasia. There were a considerable number of small pulmonary emboli, but since there was very little infarction embolism hardly seems a good explanation for leukocytosis. The renal lesion did not progress very far. It was an intracapillary type of glomerulitis with no crescent formation and no secondary changes in the tubules; it did not appear particularly active.

DR SHORT Was the liver process very active at the time of autopsy?

DR MALLORY No, the picture was variable in the different lobules, but on the whole it looked like a healed scar and not an actively progressive process.

in these pursuits. Still he is received everywhere by all conditions of men, and finds that most people are more than friendly. Men render him a rather special devotion because he is thought to be less material, less grasping, more ready than others to sacrifice his own comfort and welfare to that of those whom he serves. Presently he realizes a little sadly that this high opinion bears very little relation to his cash income.

The busy average doctor at the moment feels acutely in his pocketbook the rigors of the current inflation. He is therefore peculiarly interested in or perhaps susceptible to, economic propaganda. There is plenty of it within the profession, but he has seemingly only two choices. He may listen to the National Physicians Committee or to the Committee of Physicians for the Improvement of Medical Care or, more lately, to the Physicians Forum, and depending on his bias at the moment, may fancy that he hears the voice of red medicine or of medical fellow travelers or at least of the intellectual pinks. To confuse him further and cut down his ego, he finds that his future is being planned by Congress, sociologists and popular writers. Unpleasant comments come from almost every quarter. Some of his colleagues managing a blood bank are accused of profiting in their traffic and of being no better than vampires. He may be shocked by the statement of a wealthy elder statesman and doctor's son: "I do not fear Government taking its legitimate part in medicine any more than I fear it in education or housing. I urge the doctors to get in and pitch — not stand by on the sidelines."

Precisely what is the doctor's economic and social status? Economically he belongs to the middle class, which is being threatened from both above and below. The division of the more vocal colleagues into far-right and far-left groups is just what is happening in general society. Some name-calling is already being indulged in. Unless physicians are circumspect, they may have to face witch hunts and loyalty checks or even public trials for subversive activities. According to Townbee,\* the position of the middle class is in question now in all western countries.

\*Townbee A. J. *Civilization on Trial*. Chapter 2. Present Point in History. New York: Oxford University Press, 1948.

The middle class, really a tiny minority, has created the modern world with its technologic advances, its knowledge and its tremendous means of production. The still underprivileged majority is pressing the middle class for a fair share of the good things of life, including the "care services," of interest to all — namely, housing, social security and health. The world is caught in a conflict of ideas, and seemingly is being forced to choose between the extremes of unrestricted private enterprise, with inequalities of distribution, and unmitigated socialism, which alleges that it will divide everything equally.

Economically the physician is of the middle class but socially he is without class. His science and his art are acquired, developed and applied without regard to nation, race, creed or personal reward. In his professional life the doctor traditionally is apart from the divisions among men. If class and war have always caused the breakdown of societies, and if there is full realization that these must be eliminated now to enable the civilization to survive, may not the medical profession play a role in finding the "middle way" between apparently irreconcilable extremes?

---

#### NEW ENGLAND POSTGRADUATE ASSEMBLY

THE seventh annual postgraduate assembly of the New England state medical societies will be held at the Copley Plaza Hotel on November 3, 4 and 5. An interesting program with speakers of distinction in their special fields has been arranged and has already appeared in the *Journal* on September 30 and October 14. Particularly to be emphasized are the clinics that will be held at major Boston hospitals on the morning of November 5. The committee in charge, composed of representatives of the six New England societies, under the able chairmanship of Dr. Leroy E. Parkins, is again to be congratulated on the list of subjects and speakers that it has selected.

The New England Postgraduate Assembly, after seven years of operation in a country where events frequently succeed one another with startling rapidity, may be considered as a tradition. To be a

## THE EFFICIENCY OF MEDICAL SERVICE

FAMILY doctors have ample opportunity these days to see themselves as others see them. From such an emotional outlook as that of Ian MacLaren it was a heart-warming view, and many a patient continues to share it with those who knew the horse-and-buggy doctors at their best. In many of the mirrors held up to the physician of today, however, there is an emotional screen that removes all trace of sentiment and feeling.

The industrial or business point of view is one where efficiency sits enthroned, and where lack of efficiency is viewed with impatience. Doctors, in their daily lives, are inclined to place a higher value on the end result than they do upon the efficiency with which it is achieved. In matters seriously involving life and limb this attitude is understood and is even encouraged by thoughtless people when they tell the doctor that he is to "spare no expense" in this and that, believing that the more the service costs the better it must be. People believe this because they may have no better method of appraisal. Modern industry wants the best results too, it not only is beginning to demand them but also is aware of the fact that the efficiency with which they are achieved is a measure of their value, and to some extent of their quality as well. Although industry still employs largely the private doctor, and upon his own terms too, his methods as well as his results are being scrutinized by businessmen, by labor leaders, by engineers and by other physicians all of whom are geared to modern industry's heartless demand for efficiency as well as for good results.

How may the quality of medical service be appraised? The answer depends upon the critical capacity of the appraiser. There are probably more ways of judging medical service than there are of judging horseflesh, some are good and some are not. What is a good method for one situation may not be for another. When much is known and appreciated about the self-limitation of disease there may be created an entirely different standard of judgment. On the whole, medical service may be said to be judged by informed public opinion,

and public opinion is becoming more informed every year.

Doctors practicing in a certain locality may see themselves as the industrial physician sees them by reading Shipman's article in this issue of the *Journal*. They should remember that the author is naturally trying to emphasize the points at which friction occurs. These points are not peculiar to that industry or that region, in fact it is pointed out that similar occurrences have been noted in California. These little conflicts of opinion, of judgment and of action are rooted deep in human nature, in the competitive spirit of man and in the circumstances of the environment in which we all must live, and strive to live together.

Not only industrialists but also welfare boards, insurance carriers and compensation authorities are vividly aware of medical efficiency, or its lack, in the care of the patients in whom they are interested. When a welfare official finds that 90 per cent of the money paid in a small community goes to a single doctor (on a fee-for-service basis) and that his patients do not seem to have more serious ailments or different end results than those of the other doctors, that official is rightly suspicious of that doctor. Such doctors are scattered here and there, generally believing themselves smart in their padding activities. They are notoriously well known among people whose business it is to handle financial adjustments that involve medical services. Inefficient is a very polite adjective to describe this type of medical practice.

## HORNS OF THE DILEMMA

WITH pardonable pride, a doctor may fancy his lifework the most important in the world — especially if he is very young. When combined, as that belief usually is, with idealism and optimism and energy, it is not only pardonable but also admirable. If the youth had less regard for his profession, and less energy and idealism in its pursuit, he would not be worth his salt. Later as he measures himself against the world he finds that other activities, especially the more effective means of getting and spending, are highly esteemed, and discovers that his profession is not the most efficient

## UNITED STATES PUBLIC HEALTH SERVICE

To foster training of medical students in the mental aspects of disease, federal grants for undergraduate courses are now being offered to medical schools by the United States Public Health Service. Formerly, grants to medical schools, authorized by the National Mental Health Act, were utilized primarily for graduate training in psychiatry.

Extension of grants to the undergraduate field was recommended by the National Advisory Mental Health Council as a means of providing future physicians with basic knowledge that will help them to recognize early symptoms of mental illness, to treat cases that do not require the services of a specialist and to apply psychiatric principles in the treatment of all types of illness.

Applications must be made to the Mental Hygiene Division of the Public Health Service by October 15, 1948. Grants will cover a three-year period beginning July 1, 1949, and will be paid in annual installments.

## WATER-POLLUTION ACT

The federal Government has finally been given the power to control stream pollution under the Barkley-Taft Water Pollution Act, passed as one of the last acts of the eightieth Congress.

Under the Act, *Scientific American* reports, the Federal Works Administration is permitted to lend states and municipalities up to one third the cost of new sewage-treatment and pollution-abatement facilities. A Public Health Service research and training center on pollution control is to be located in Cincinnati, Ohio.

Eight states — Illinois, Indiana, Kentucky, New York, Ohio, Pennsylvania, Virginia and West Virginia — have meanwhile signed a regional agreement to clean up the beautiful Ohio, a stream with the reputation of being the most polluted river in the world.

## CORRESPONDENCE

## THE FAMILY PRACTITIONER

*To the Editor:* Please let me thank you for your editorial "Down East Doctor," which I enjoyed very much indeed. I also want to tell you that I find the *Journal* one of the most informative and valuable that comes to my desk among a large number of medical and general publications.

The problem that you raised concerning the preservation of the general practitioner (I think "family practitioner" is a better term) is one to which all of us should give out best attention and intelligent effort.

It appears to me that many hospital trustees, hospital administrators, certain specialists and the American College of Surgeons, unwittingly I trust, are doing much that may lead to elimination of the family physician. The problem is one not only for small communities but also for large cities. I know of hospitals in which the general practitioner is not permitted to apply splints and bandages to uncomplicated injuries or assist in short operations or open superficial abscesses, not because he is incompetent to do these things, not because he is dishonest or unethical, not because he is not a gentleman, but solely because he is not a specialist.

It seems to me that this is one of our most pressing problems today. It is only, I think, through preservation of the family practitioner, that we can prevent state medicine, and I think you will agree with me that state medicine of itself will lead to a totalitarian government, which unquestionably would soon become a slave government. That, of course, is the lesson that history teaches so clearly, and we cannot expect anything else if we follow the same dismal path.

Again let me thank you for the excellent *Journal*.  
MALCOLM THOMPSON, M.D.  
Louisville, Kentucky

## BOOK REVIEWS

*Biochemistry of Cancer*. By Jesse P. Greenstein. 8°, cloth, 359 pp., with 39 illustrations and 104 tables. New York: Academic Press, Incorporated, 1947. \$7.80.

This book is much more comprehensive and varied than the subject indicates. Oncology is the author's term for can-

cer research. The "oncologic sciences" are clinical medicine, surgery, pathology, radiation, physics, genetics, immunology, endocrinology and biochemistry — in short, the entire field of medicine. Some of the definitions used are hardly those in common use by cancer practitioners. "The term carcinoma may be applied to tumors which arise from epithelial tissue" and "the term sarcoma may be applied to tumors arising from connective and muscle tissues." The author does not distinguish between benign and malignant tumors in making these definitions although in another section he enlarges on the close margin between malignancy and benignancy. Again, "the neoplasms which ensue are known as cancers or tumors." The writer raises an interesting hypothesis regarding the capacity of tumors for autonomous growth — that a benign growth is largely dependent upon the organism and hence not truly autonomous, whereas a malignant growth is largely autonomous and independent of the organism. He suggests that a cancer of the prostate that responds to hormone therapy is relatively non-autonomous and hence benign; later, it becomes refractory to treatment and is autonomous and thus malignant.

In the chapter on the general phenomena and taxonomy of cancer Greenstein deals with the experimental induction of tumors and mentions a few of the known carcinogenic agents such as tar, polycyclic hydrocarbons, azo dyes, zinc salts, radium salts, x-rays and cysticercus. He also refers to cancerous transformation of animal tissues *in vitro*, the growth and the vascular reactions of tumors, plant tumors, the melanomas of fish and tissue-immunity reactions.

One chapter considers the extrinsic chemical factors, — the chemicals that are known to induce cancer. Among these are 1, 2, 5, 6-dibenzanthracene, and 3, 4-benzpyrene. The technique used in studying and synthesizing carcinogenic hydrocarbons is described. Much work has been done in animals to determine the types of tumors induced, the susceptibility of different strains of the hydrocarbons and the fate of the injected hydrocarbons. Many deaths have occurred from cancer of the scrotum in workers exposed to coal tar.

Intrinsic factors are defined as agents that possess a biogenic origin, including hormones and viruses. The chemistry of hormones and similar synthetic preparations and the use of these materials in experimental animals are discussed.

Chemotherapy has been of little value in the therapy of cancer. Coley's toxins when first prepared and administered by Coley seemed of some help in certain cancer patients, but later the results could not be obtained by Coley or others. Polysaccharide injections and the use of Fowler's solution and colchicine offered high hopes, but all such methods have failed.

The author is at his best in discussing the chemistry of tumors, since much of the work mentioned has been done by him or under his direction. Extensive analyses have been made of the chemical structure of normal tissues and of neoplasms, the oxygen consumption of normal and neoplastic tissues, the activity of phosphatases, the glycogen content and many other subjects. Two hundred and forty-seven references are given for the material presented in this chapter.

*Psychopathology and Education of the Brain-Injured Child*. By Alfred A. Strauss, and Laura E. Lehtinen. 8°, cloth, 206 pp., with 46 illustrations. New York: Grune and Stratton, 1947. \$5.00.

This monograph is based on research work conducted by the authors and in part previously published in various periodicals. The text is divided into two parts: psychopathology and teaching. The first part is prefaced with a historical review of the subject, followed by chapters on anatomy and function of the brain, perception and perceptual disturbances, thinking disorders, behavior disorders, testing and diagnosis of brain injury in children. The second part, on education, considers the general principles of education, and the teaching of arithmetic, reading and writing. An appendix presents a study of a deaf child with a brain injury by Mary A. Bair, an excerpt from an unpublished essay. The text is documented with a number of case histories. References to the literature are printed as footnotes on the appropriate pages. The book is well published and should prove of interest to neurologists and psychiatrists.

New England tradition is in itself a mark of distinction

Each year the Postgraduate Assembly has surpassed its previous record in attendance and — a very tangible sign of success — its attractiveness to technical exhibitors. It should be to the advantage of the New England Council of State Medical Societies some day to take over the Assembly as its own project. Present indications suggest that the Assembly might even be able to furnish the Council with those fiscal assets so necessary to existence.

## BLUE CROSS-BLUE SHIELD

### MEDICAL SECRETARY MEETINGS

As part of the Blue Shield professional relations program a series of group meetings with medical secretaries is being conducted throughout the Commonwealth.

These group discussions are designed to provide medical secretaries with current and detailed information concerning Blue Shield benefits, claim report forms, Blue Shield income limitations, rules and regulations and other pertinent information that will help to minimize or eliminate errors, thereby providing better service to participating physicians and Blue Shield patients.

These informal discussions of mutual problems have proved to be very worth while. Meetings have been scheduled for approximately forty towns and cities during the next eight months.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### REIMBURSEMENT OF PHYSICIANS UNDER EMIC PROGRAM

The Massachusetts Department of Public Health has received notification from the Children's Bureau, Washington, D. C., that all federal reimbursements for emergency maternal and infant care services, as authorized under the EMIC program, will terminate as of June 30, 1949.

That Massachusetts physicians may be assured reimbursement for such services. The Massachusetts Department of Public Health requests that all outstanding bills for care authorized under the Massachusetts EMIC program be submitted to the Division of Maternal and Child Health, Massachusetts Department of Public Health, 73 Tremont Street, Boston, not later than May 1, 1949.

Provision for maternal care under this program has been authorized for the period September 3, 1943, to April 4, 1948, for infant care such services will terminate as of April 4, 1949.

## VACCINE FOR ROCKY MOUNTAIN SPOTTED FEVER

The United States Public Health Service has announced that it is discontinuing the manufacture of vaccine for Rocky Mountain spotted fever. This vaccine is now available from commercial manufacturers so that physicians who wish to use it will have no difficulty in purchasing the product.

For many years the Rocky Mountain Laboratory was the only source from which vaccine for this disease could be obtained. The first variety of the vaccine was prepared from the bodies of infected ticks and played an important part in reducing the numbers of cases and deaths in the valleys of the Rocky Mountains, where the disease had been prevalent for many years.

The tick-tissue type of vaccine has now been superseded by the chick-embryo type. The commercial manufacturers will be supplying only the new variety. When the present supply of tick-tissue vaccine on hand is depleted, the old variety will no longer be available. The Rocky Mountain Laboratory will make the tick-tissue vaccine available as long as the present supply lasts.

## CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The November schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Salem	November 1	Paul W. Hugenberger
Haverhill	November 3	William T. Green
Lowell	November 5	Albert H. Brewster
Gardner	November 9	Carter R. Rowe
Springfield	November 16	Garry deN. Hough, Jr.
Pittsfield	November 17	Frank A. Slowick
Brockton	November 18	George W. Van Gorder
Hyannis	November 18	Paul L. Norton
Worcester	November 19	John W. O'Meara
Fall River	November 22	David S. Grice
Greenfield	November 22	Charles L. Sturdevant

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

## MISCELLANY

### APPOINTMENT

Dr. Lendon Snedeker, of Brookline, has been appointed assistant administrator of the Children's Medical Center of Boston.

### BODY BLOW

Blue Cross in British Columbia, according to an Associated Medical Care Plans release, will be forced to liquidate on December 31, 1948. This will mark the first time that a well established voluntary plan has been forced out of existence in North America by the advent of compulsory health insurance.

British Columbia's Blue Cross has been unable to meet conditions imposed by the provincial Government's new hospital insurance act.

## UNITED STATES PUBLIC HEALTH SERVICE

To foster training of medical students in the mental aspects of disease, federal grants for undergraduate courses are now being offered to medical schools by the United States Public Health Service. Formerly grants to medical schools, authorized by the National Mental Health Act, were utilized primarily for graduate training in psychiatry.

Extension of grants to the undergraduate field was recommended by the National Advisory Mental Health Council as a means of providing future physicians with basic knowledge that will help them to recognize early symptoms of mental illness, to treat cases that do not require the services of a specialist and to apply psychiatric principles in the treatment of all types of illness.

Applications must be made to the Mental Hygiene Division of the Public Health Service by October 15, 1948. Grants will cover a three-year period beginning July 1, 1949, and will be paid in annual installments.

## WATER-POLLUTION ACT

The federal Government has finally been given the power to control stream pollution under the Barkley-Taft Water Pollution Act, passed as one of the last acts of the eightyeth Congress.

Under the Act, *Scientific American* reports, the Federal Works Administration is permitted to lend states and municipalities up to one third the cost of new sewage-treatment and pollution-abatement facilities. A Public Health Service research and training center on pollution control is to be located in Cincinnati, Ohio.

Eight states—Illinois, Indiana, Kentucky, New York, Ohio, Pennsylvania, Virginia and West Virginia—have meanwhile signed a regional agreement to clean up the beautiful Ohio, a stream with the reputation of being the most polluted river in the world.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Tuberculosis: A discussion of phthisiogenesis, immunology, pathologic physiology, diagnosis, and treatment.* By Francis M. Pottenger, A.M., M.D., LL.D., medical director, the Pottenger Sanatorium and Clinic for Diseases of the Chest, Monrovia, California. 8°, cloth, 597 pp., with 105 illustrations. St. Louis: The C. V. Mosby Company, 1948. \$12.00.

*The Epithelia of Woman's Reproductive Organs: A correlative study of cyclic changes.* By George N. Papanicolaou, M.D., Ph.D., professor of clinical anatomy, Cornell University Medical College; Herbert F. Traut, M.D., professor of obstetrics and gynecology, University of California Medical School; and Andrew A. Marchetti, M.D., associate professor of obstetrics and gynecology, Cornell University Medical College. 4°, cloth, 53 pp., with 22 plates. New York: The Commonwealth Fund, 1948. \$10.00.

*Atlas of Plastic Surgery.* By Morton I. Berson, M.D. 4°, cloth, 304 pp., illustrated. New York: Grune and Stratton, 1948. \$15.00.

*Diabetes Mellitus in General Practice.* By Arthur R. Colwell, M.D., associate professor of medicine and director of medical specialty training, Northwestern University Medical School, attending physician, Evanston Hospital, Evanston, Illinois, and consulting physician, Wesley Memorial Hospital, Chicago. 8°, cloth, 350 pp., with 24 illustrations. Chicago: The Year Book Publishers, Incorporated, 1947. \$5.25.

*Telepathy and Medical Psychology.* By Jan Ehrenwald, M.D. With a foreword by Gardner Murphy. 8°, cloth, 212 pp. New York: W. W. Norton and Company, Incorporated, 1948. \$3.00.

*Brief Psychotherapy: A handbook for physicians on the clinical aspects of neuroses.* By Bertrand S. Frohman, M.D. With the collaboration of Evelyn P. Frohman, and with a foreword by Walter C. Alvarez, M.D. 12°, cloth, 265 pp. Philadelphia: Lea and Febiger, 1948. \$4.00.

*Case Histories in Clinical and Abnormal Psychology.* Edited by Arthur Burton, associate professor of psychology, Willamette University; and Robert E. Harris, associate professor of medical psychology, University of California. 8°, cloth, 680 pp. New York and London: Harper and Brothers, 1947. \$4.00.

*Hormones and Behavior: A survey of interrelationships between endocrine secretions and patterns of overt response.* By Frank A. Beach, professor of psychology, Yale University. With a foreword by Earl T. Engle. 8°, cloth, 368 pp. New York: Paul B. Hoeber, Incorporated, 1948. \$6.50.

*The Treatment of Rheumatism in General Practice.* By W. S. C. Copeman, O.B.E., M.A., M.D. (Cantab.), F.R.C.P. (London), physician in charge, Department of Chronic Rheumatic Diseases, West London Hospital, physician, B.R.C.S. Clinic for Rheumatism, Peto Place, Hospital of St. John and Elizabeth and Cheyne Hospital for Children, and chairman of the Chartered Society for Physiotherapy and medical secretary, Empire Rheumatism Council. Fourth edition. 8°, cloth, 258 pp. Baltimore: The Williams and Wilkins Company, 1946. \$4.00.

*The Pathology of Nutritional Disease.* By Richard H. Follis, Jr., M.D., associate professor of pathology, Duke University School of Medicine, Durham, North Carolina. 8°, cloth, 291 pp., with 71 illustrations. Springfield, Illinois: Charles C. Thomas, 1947. \$6.75.

## NOTICES

## ANNOUNCEMENT

Dr. Lewis S. Pilcher announces the removal of his office to 1180 Beacon Street, Brookline.

## EXAMINATION FOR MEDICAL OFFICER POSITIONS

An examination has been announced by the United States Civil Service Commission for filling medical-officer positions at salaries ranging from \$4479 to \$6235 a year. The positions are located in Washington, D. C., throughout the United States and in the Panama Canal Zone, in such agencies as the Indian Service, Panama Canal Service, United States Public Health Service, Army, Veterans Administration, Civil Aeronautics Administration and Railroad Retirement Board.

No written test will be required. To qualify, applicants must be graduates of a medical school and must be currently licensed to practice medicine and surgery. (The requirement of a current license will be waived for certain persons and positions.) For positions paying \$4479 and \$5232, applicants must have completed a full internship, either general rotating or in a specialty (this requirement is waived for some positions), and for positions paying \$5232 and \$6235, they must have had professional medical experience. Maximum age limits for these positions are as follows: for Panama Canal Service, forty-five years, for Indian Service, fifty years, for other agencies, sixty-two years. For persons entitled to veteran preference, the forty-five-year and fifty-year age limits are waived to sixty-two years, and the sixty-two-year age limit is waived without limitation. Detailed information on requirements is given in the examination announcement.

Information and application forms may be obtained at most first-class and second-class post offices, from Civil Service regional offices or from the United States Civil Service Commission, Washington 25, D. C. Applications will be accepted in the Commission's Washington office until further notice.

## MIDDLESEX EAST DISTRICT MEDICAL SOCIETY

Meetings of Middlesex East District Medical Society will be held on the following dates: November 17, 1948 (Dr. Robert R. Linton will discuss the surgical and Dr. A. Stone Freedberg the medical aspect of "Thromboembolic Disease"); January 19, 1949 (discussion of medical, surgical and obstetric case, entitled "Stump the Experts"); March 23, 1949 (symposium on hypertension, with Dr. Lewis Dexter discussing the medical, Dr. J. C. White the surgical and Dr. Sanford H. Moses the obstetric aspects, and with Dr. George D. Bissell considering the general practitioner's problems); and May 11, 1949 ("Ladies' Night," with dancing and a selected speaker on a nonmedical subject).

## AMERICAN CANCER SOCIETY, INCORPORATED

A medical symposium on the cancer problem will be held by the American Cancer Society, Incorporated, at the Hotel Commodore, New York City, on November 6 and 7. The program will include discussions on the following subjects: "The Cancer Problem Today," "The Problem of Treatment—Recent Advances," "The Problem of Cancer of the Lung," and "Cancer Research, Cancer Education and the Cancer Problem in General Medical Practice."

## AMERICAN FEDERATION FOR CLINICAL RESEARCH

The annual meeting of the Eastern Section of the American Federation for Clinical Research will be held at Temple University School of Medicine, Philadelphia, on Saturday, December 4.

## INTERSTATE POSTGRADUATE MEDICAL ASSOCIATION OF NORTH AMERICA

The International Medical Assembly of the Interstate Postgraduate Medical Association of North America will be held in the Public Auditorium, Cleveland, Ohio, from November 9 to 12.

(Notices continued on page xv)

## Now It's Neckties Made of Milk!

*Fellow in Andy Botkin's Tavern the other day was boasting about a trick necktie he was wearing made out of a by-product of milk "Took 33 pounds of milk to make this tie," he says*

Bill Webster was unimpressed "Personally," he says, "I'd rather drink the milk Just as I wouldn't change one glass of good American beer for a necktie made from thirty barrels of it!"

*Yes—modern science being what it is—seems like you can make "anything out of anything" these days. But in the case of milk, well I guess drinking it is still a whole lot better than just wearing it*

Of course there are a whole lot of other ways of abusing goods and beverages—like a fellow who doesn't appreciate a glass of beer enough to drink it slowly and in moderation

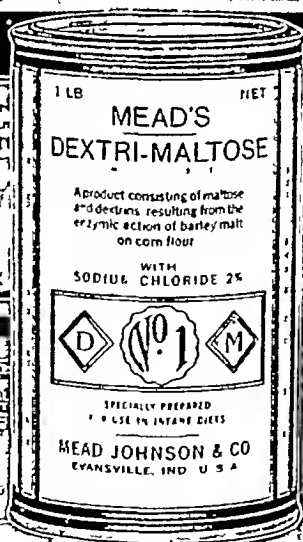

*But from where I sit, most people who enjoy a wholesome beverage like beer or ale are moderate—because beer itself is a beverage of moderation*

Joe Marsh

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri Maltose

## INTUSSUSCEPTION IN CHILDHOOD\*

### Experiences from 610 Cases

ROBERT E. GROSS, M.D., J. AND PAUL F. WARE, M.D.†

BOSTON

INTUSSUSCEPTION is a form of intestinal obstruction that demands immediate recognition and treatment if mortality rates are to be kept at a minimum. The condition is particularly common in the first few years of life, and it must be constantly in the minds of pediatricians and the general practitioners who deal with babies and young children. Much has been written concerning the recognition and the forms of therapy for this type of mechanical obstruction. The extensive material that we have been privileged to handle prompts us to call attention again to the salient features in diagnosis of the condition and to review briefly the methods of treatment, paying particular attention to a form of therapy that has proved to be very beneficial for subjects requiring resection of an intussusception. Several previous reports have been made on the cases of intussusception at the Children's Hospital in Boston. In 1934 Ladd and Gross<sup>1</sup> studied 372 of these patients. The series has now extended to 610 cases of intussusception in infants and children; the present report including all cases treated up through 1947 by various members of the visiting staff and the house personnel. Recent years have shown a steady decline in mortality rates, particularly in the cases with a poor prognosis in which resection has been necessary.

The interval between onset of symptoms and institution of treatment is of paramount importance, and the mortality rates will more nearly approach zero the more frequently treatment is instituted within twenty-four hours of onset. Intussusception is truly an acute surgical emergency, and a heavy diagnostic responsibility is placed upon the general practitioner or pediatrician who first sees these patients. The surgeon deserves some credit for improved results in the treatment of intussusception, as is shown by comparison of the two columns

of Table 1, which lists the mortality rates for patients with similar durations of symptoms in the years 1928-1939, compared to 1940-1947. However, greatest emphasis must be attached to the facts that since 1928 in 180 patients treated in this hospital the duration of symptoms has been less than twenty-four hours and that operation has been carried out without fatality. This is a strong tribute to the physicians of the community who have

TABLE 1 *Relation between Mortality and Duration of Symptoms*

DURATION OF SYMPTOMS <i>hr</i>	MORTALITY	
	1928-1939	1940-1947
Less than 24	0	0
24-36	25	9
36-48	33	12
48-72	21	15
72-96	38	15

recognized these cases early and have referred them for treatment while the surgical problem is still a simple one.

The falling mortality rates through the years covered by this series are indicated in Figure 1, showing a gradual but steady improvement, the latest rates being 2.7 per cent.

### ETIOLOGY

When intussusception occurs in adult life, a definite mechanical cause for the telescoping can usually be found, Meckel's diverticulum, polyps and various types of bowel tumors are the inciting factors in more than half the cases in adults. Likewise, the intussusceptions that occur in late childhood are apt to have some demonstrable, underlying lesion. In striking contrast, intussusceptions in early life rarely have any mechanical factor that can be clearly identified as the cause of the invagination.

\*From the Surgical Service, The Children's Hospital and the Department of Surgery, Harvard Medical School.  
†Ladd Professor of Children's Surgery, Harvard Medical School; surgeon-in-chief of Children's Hospital.  
Resident surgeon, Children's Hospital.

Various theories have been advanced to explain the origin of intussusception in infants enlarged Peyer's patches, ileocecal neuromuscular dysfunction, enteric infections, excessive catharsis and the transition from breast or bottle feeding to a more solid diet have often been indicted as causes, but it is extremely difficult to prove that these have played an etiologic role. Discernible mechanical factors could be shown in only 5.4 per cent of the cases in this series, as follows: Meckel's diverticu-

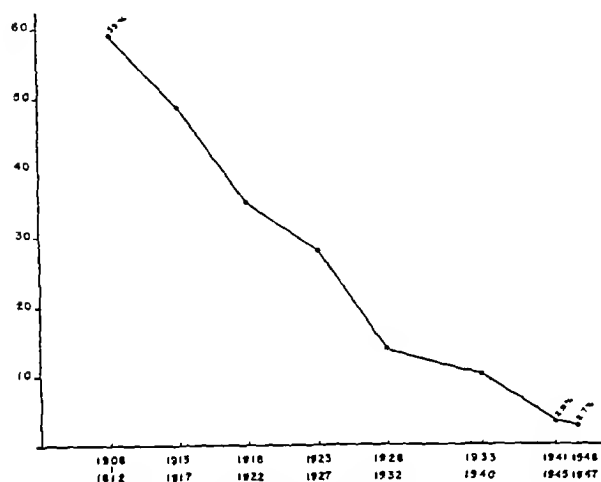

FIGURE 1 Mortality Rates in 610 Cases of Intussusception, 1908 through 1947

lum, 29 cases, intestinal polyp, 4 cases, lymphoma of bowel, 2 cases, and duplication of terminal ileum, 1 case

#### CLASSIFICATION

Invaginations are identified as involving primarily the small or the large bowel. Further classification is indicated by the portion of the alimentary system that is the leading point (intussusceptum) and is the receiving segment of intestine (intussusciptum). An "ileocolic" type describes a prolapse of the lower ileum through the ileocecal valve into the colon; it is the most commonly encountered form. A more complicated variant of this type is the ileoileocolic, in which ileum telescopes into ileum, and this entire mass passes into the colon. In the present series the types encountered were ileocolic, 76 per cent, ileoileocolic, 14 per cent, jejunoileal or ileoileal, 5 per cent, colocolic, 2.1 per cent, multiple, 0.7 per cent, and type not stated, 2.2 per cent.

#### SYMPTOMS AND SIGNS

In this series 440 cases, or 72 per cent, were found in the first year of life, with the peak of incidence between the third and eleventh months, in which 68 per cent of the cases occurred. Eighty-four per cent of the cases in the series occurred by

the age of two years, with a scattering of cases in age groups between three and twelve years. The youngest was three days of age. Sixty-five per cent of the patients were males.

The onset of intussusception is usually marked by sudden, severe, paroxysmal seizures of abdominal pain in a previously well infant of superior nutrition and development. The pain recurs at intervals of a few minutes, the colicky or recurring nature being strongly suggestive of obstruction of the small intestine. In the first few hours, the child usually appears quite comfortable and even playful between attacks of pain, but at later stages is apt to be pale and exhausted, and often sinks off into sleep between the paroxysms. The young infant usually manifests abdominal pain by forceful drawing up of the legs onto the abdomen, and holding the breath in a grunting manner or uttering an agonizing cry. Rhythmic pain was observed in more than 95 per cent of the cases in this series. Vomiting is an early symptom and is present in well over 90 per cent of the patients. With the passage of time and with the increase of obstruction, pallor, sweating and restlessness are found as the child approaches a state of shock. In neglected cases of several days' standing, the long-continued intestinal obstruction produces a moribund state in which there is collapse and severe dehydration.

The appearance of blood in the stool occurs in about 85 per cent of the cases within twenty-four hours. In about half of these the bleeding is gross and may be copious, in the remainder it is discovered by chemical tests on the stools. The first stool passed after the onset of intussusception is usually normal, but after an interval of ten or twelve hours the next stool (or enema returns) usually reveals gross or occult blood. Bleeding may be mild, moderate or almost exsanguinating. The amount of blood appearing in the stool is directly related to the degree of strangulation occurring in the intussusception.

Dr William E. Ladd frequently made the statement that "intussusception produces such a characteristic picture that it is possible to make the diagnosis over the telephone when the mother relates the story."

The importance of careful abdominal examination is evident from the fact that a mass is palpable in about 85 per cent of the cases. Small-bowel invaginations are quite mobile and only rarely palpable. More commonly an elongated tumor can be felt in the right upper quadrant or anywhere along the course of the colon. Usually, the mass is not particularly tender. An intussusception in the region of the splenic flexure or in the hepatic flexure may be difficult to feel because it lies under the costal margin or under the edge of the liver. Not infrequently a discrete mass cannot be outlined, and yet the examiner meets a definite resistance or fullness in the right upper quadrant or

in the epigastrium. On some occasions (if the baby is examined during a bout of pain) it is possible for the palpating fingers to follow the progression of an intussusception mass with each seizure and to feel

quarter of the cases, an intra-abdominal mass can be felt by rectal examination. This finding is particularly helpful if the child is straining or is so tense that palpation of the anterior abdominal wall

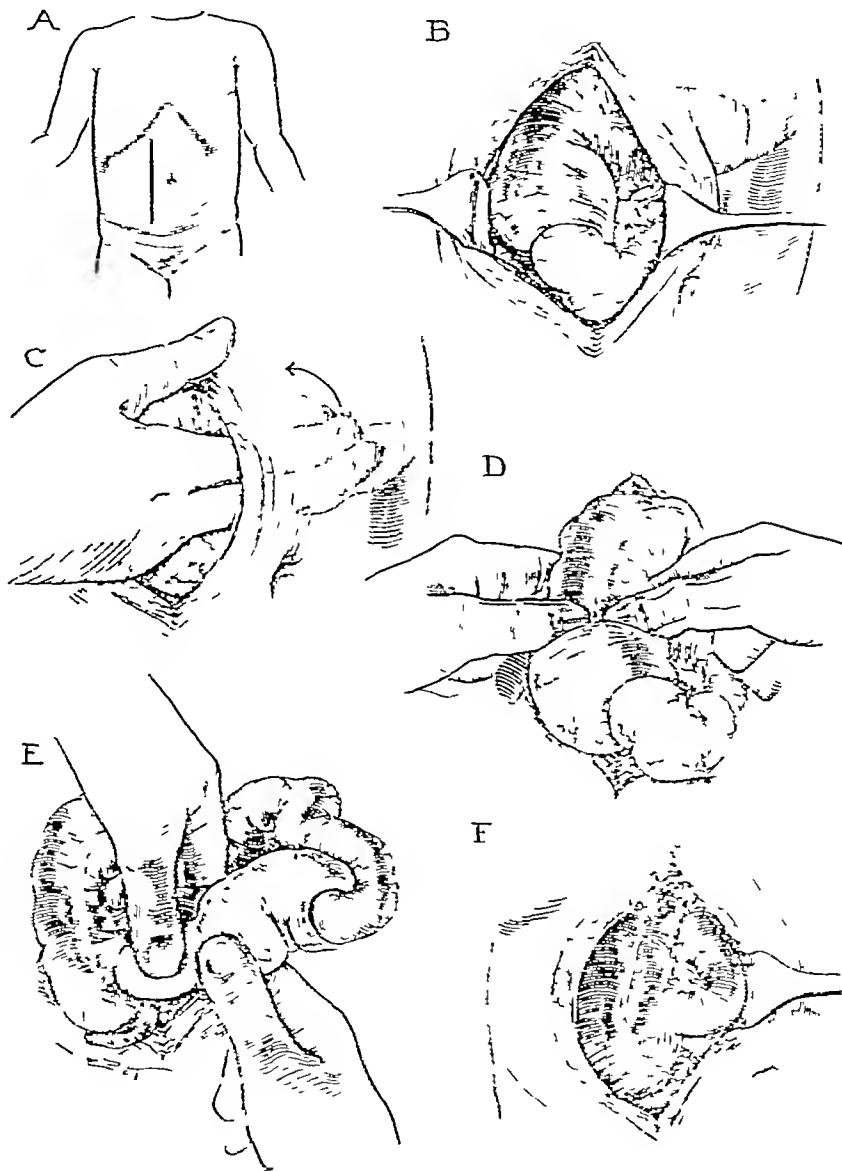

FIGURE 2. Typical Operative Reaction of Intussusception. A shows a right-rectus-muscle mass on retracting the muscle belly laterally. B retractor intussusceptum into the colon almost to the splenic flexure. C finger is retracted into the peritoneal cavity. D on the back retractor intussusceptum as far as possible by intra-abdominal manipulation. E delivery of the entire mass through the wound for correction of the reaction when retractor intussusceptum has been reduced to the ascending colon. F retractor intussusceptum being squeezed back from the terminal ileum and F the viscera returned to the abdomen (the apparatus is rarely removed).

its wall harden as its tone is increased by the peristaltic activity.

Rectal examination with bimanual palpation of the abdomen, is often informative. In about a

quarter of the cases, an intra-abdominal mass can be felt by rectal examination. This finding is particularly helpful if the child is straining or is so tense that palpation of the anterior abdominal wall

prolapsed rectum. However, differentiation from a prolapse could be quickly made by the insertion of a finger between the mass (intussusceptum) and the encircling anus—which would be impossible if the mass were a prolapse.

Roentgenologic aid is not necessary in the average case of intussusception, the diagnosis can be made without hesitation from the history and physical findings. In about a tenth of the cases the diagnosis is in doubt, and the roentgenologist's help should be sought. A film of the abdomen, without a contrast medium, may show the intussuscepting mass and some dilatation of intestine proximal to it. In the great majority of cases, the intussusceptum has progressed into the colon so that a barium enema shows a filling defect in the column of barium and a post-evacuation film demonstrates a thin shell of barium remaining around and outlining the intussusceptum.

### TREATMENT

#### *Nonoperative Measures*

Almost universally, surgical intervention has become the treatment of choice, but there are still a few advocates of therapy by colonic insufflation of air or fluid. The more recent devotees of this method suggest the rectal injection of a barium mixture, the reduction of the intussusception being watched under fluoroscopic control. We have used this on several occasions with rapid and complete reduction of the intussusception, but we believe that it should never be done except with the consent of, and in the presence of, the surgeon who must accept the responsibility of operating on the child if the reduction by hydrostatic pressure is unsuccessful. In general, there are several very sound objections to the rectal injection of fluids for the reduction of an intussusception: many of these patients later come to operative reduction because of irreducibility or because of uncertainty of complete reduction, and operation is therefore delayed, with a corresponding increase in mortality expectancy, an intestinal polyp, tumor or Meckel's diverticulum may be completely overlooked, and the method is useless when a portion of the intussusception is above the ileocecal valve—a small-bowel or an ileoileocolic intussusception will be left incompletely reduced.

#### *Operative Measures*

As a first step in hospital therapy, gastric suction should be instituted to prevent vomiting and pulmonary aspiration. Furthermore, the child should be properly covered, to reduce loss of body heat. Children and babies with intussusception present emergency situations, which should be treated by laparotomy as soon as this procedure can be safely performed. If the duration of the symptoms has been only a few hours and vomit-

ing has not been excessive, operation may be performed at once, and the fluid balance can be restored in the postoperative period. In contrast, immediate operation is dangerous when there has been excessive dehydration or blood loss, when such conditions exist, it is important to correct them partially before operation by infusion of glucose solution, plasma or whole blood. Although operation should not be delayed more than an hour or two at the most, this preoperative control of shock is of fundamental importance.

We have found open-drop ether very satisfactory for average cases of intussusception, but we believe that cyclopropane is preferable for the more seriously ill children. In extremely ill babies, the abdominal exploration is more safely done under procaine infiltration of the abdominal wall.

*Reduction of intussusception.* Regardless of the position of a presenting mass, the abdomen should be opened through a generous, right-rectus-muscle incision (Fig. 2). Lateral retraction of the rectus-muscle belly gives a stronger postoperative wound than a muscle-splitting incision. The difficult phase of reduction usually occurs in the region of the ileocecal valve or terminal ileum, hence, the incision is placed in anticipation of this. The first part of the reduction is conducted intra-abdominally, the head of the intussusceptum is milked backward along the colon as far as possible. The remaining mass can then usually be pulled outside the abdomen, where it is handled with greater facility. Excessive congestion and edema of the mass can be partially reduced if one maintains annular pressure over it with the fingers for a few minutes. Excessive drying should be avoided by the dripping of hot saline solution upon the mass from time to time. The reduction is continued by *taxis*—rather than an attempt to disengage the intussusception by traction. Serosal tears, if small, are of little consequence but constitute a warning of impending perforation, and the remainder of the reduction should be extremely gentle or else resection should be seriously considered. If serosal tears are large they should be appropriately repaired after reduction of the intussusception has been completed. In our entire series 90 per cent of the intussusceptions were manually reduced, in the last few years it has been possible to reduce about 95 per cent of them. At the completion of reduction, bowel of questionable viability can often be improved by covering for a few moments with a hot saline pack. If the intestine improves in color or if peristalsis appears on stimulation, resection is unnecessary.

Even an experienced surgeon may have difficulty in deciding when an intussusception is irreducible and should be treated by resection. Persistence in efforts at reduction will frequently be successful and will avoid resection. On the other hand, one should not persist in reduction maneuvers, only to be forced eventually to resection in an exhausted

babies. Indications for resection are threefold: if the mass is irreducible, it must obviously be excised; if the bowel is perforated or nonviable or has a doubtful viability, resection is in order, and if one is dealing with a very ill patient, no attempt should be made to reduce the intussusception — instead it should be immediately removed. In some of these critically ill babies it might be possible to reduce the intussusception and indeed to have a viable intestine, but the disengagement of the bowel releases “toxic” products into the circulation that are sufficient to produce uncontrollable shock. Hence, it is better to avoid reduction (though this might be technically feasible) and to remove quickly the entire mass so that all necrotic material can be completely removed from the body. I am sure that this decision has on several occasions helped us to save a baby who would have been lost if reduction of the intussusception had been carried out.

It is the policy of this clinic to do no more than absolutely necessary in the operative treatment of intussusception. However, this does not need to be a hard-and-fast rule. The appendix is rarely removed, this incidental procedure should be done only in the occasional case in which the general condition of the child is satisfactory and will allow an additional step. When a Meckel's diverticulum is found, it is removed if it is gangrenous or if the patient's status is completely satisfactory. Under other circumstances it is better judgment to leave removal of a polyp or diverticulum until a second operation ten days or two weeks later.

**Resection and lateral anastomosis.** For irreducible intussusception (or for gangrenous bowel) this procedure has been employed with decreasing frequency in our series of cases — and indeed has been almost abandoned. A total of 18 cases have been so treated with 3 recoveries — a mortality of 83 per cent. These primary anastomoses were all performed more than a decade ago. In our opinion, there are several reasons why primary anastomosis is not the best surgical procedure for the treatment of an intussusception that requires resection: a child with an irreducible intussusception — or with a gangrenous intestine — is invariably seriously ill, and hence, a lengthy procedure, such as completion of a primary anastomosis, may be too productive of shock, whereas, a shorter operation might be tolerated (this time factor is particularly important in younger age groups, which formed the majority of our series), open anastomosis with spillage of heavily inoculated bowel contents into a devitalized peritoneal cavity (even though this contamination is minimal) is diametrically opposed to sound surgical principles — *asepsis* is a factor of the greatest importance for survival of these children, and primary anastomoses should not be performed because one fears uncontrollable loss of fluid and electrolytes from a double-barreled en-

terostomy — present-day fluid therapy makes it quite possible to control such losses even in small babies, and furthermore, the enterostomy does not have to be left open for a long time but can be closed in six or seven days.

**Open double enterostomy.** In 23 patients a resection was performed for irreducible intussusception (or gangrenous intestine). Paul-Mixer tubes or catheters were sewed into the cut-off (open) ends of the ileum and colon, and then these entubed ends were drawn out through the abdominal wall, which was closed around them. There were 5 recoveries — a mortality of 77 per cent.

We believe that this procedure is somewhat better than direct anastomosis, chiefly because the operating time is shortened for these poor-risk patients. However, double enterostomy (cutting off the intussusception mass while the abdomen is still open) is a poor procedure because of the inevitable soiling (however slight) of the peritoneal cavity at the time of intra-abdominal resection and decompression of the obstructed bowel. Although these children frequently recovered from a rapidly executed procedure, many of them died a few days later from an overwhelming peritonitis. We believe that this type of operation should be condemned.

**Aseptic Mikulicz resection.** When resection has been necessary, the procedure of choice in our experience has been the “closed aseptic, Mikulicz resection” (Fig 3). By this, we mean that the segment to be removed is kept closed while it is freed from its mesenteric or mesocolonic attachments and is dragged out through the abdominal wound, which is then closed in layers around the bases of the two limbs, and the diseased bowel is not cut off until the skin has been completely sutured. (It is well to sew together the two limbs of ileum or colon that will remain just beneath the abdominal wall.) *By these maneuvers there is no possibility of peritoneal contamination.* If the intestine above the intussusception is so distended that it must be deflated to facilitate the abdominal-wall closure, the aspiration should not be done with a needle. Although such needling is fairly safe if the hole is immediately closed with an appropriate suture, in some cases momentary regional soiling may be sufficient to lead to a subsequent fatal peritonitis. If deflation of intestine is required, it is best to accomplish this by means of an “intestinal leech” such as that described by Swenson,<sup>2</sup> applied immediately above the intussusception, and exteriorization of the loop to which the decompression apparatus has been attached. In this way intestinal deflation can be accomplished without the slightest danger of peritoneal contamination. This type of resection has several obvious advantages: the operating time is short, shock is minimized, immediate decompression is accomplished, and asepsis is rigidly preserved.

We have not encountered difficulty in maintaining fluid and electrolyte balances during the time when ileostomies or colostomies have been open. Modern parenteral therapy makes it possible to compensate for juices that are lost from an enterostomy. Furthermore, it is important to emphasize that a crushing clamp can be applied to cut down the septum between the two spurs within a few

nine months, ten months, thirteen months, twenty months, two years and seven years.

Although this closed, aseptic, exteriorization method has given us results vastly superior to what was obtained a decade or more ago, they are not so good as the recent excellent record of Dennis,<sup>3</sup> who has performed 8 resections with primary intestinal anastomosis, all patients recover-

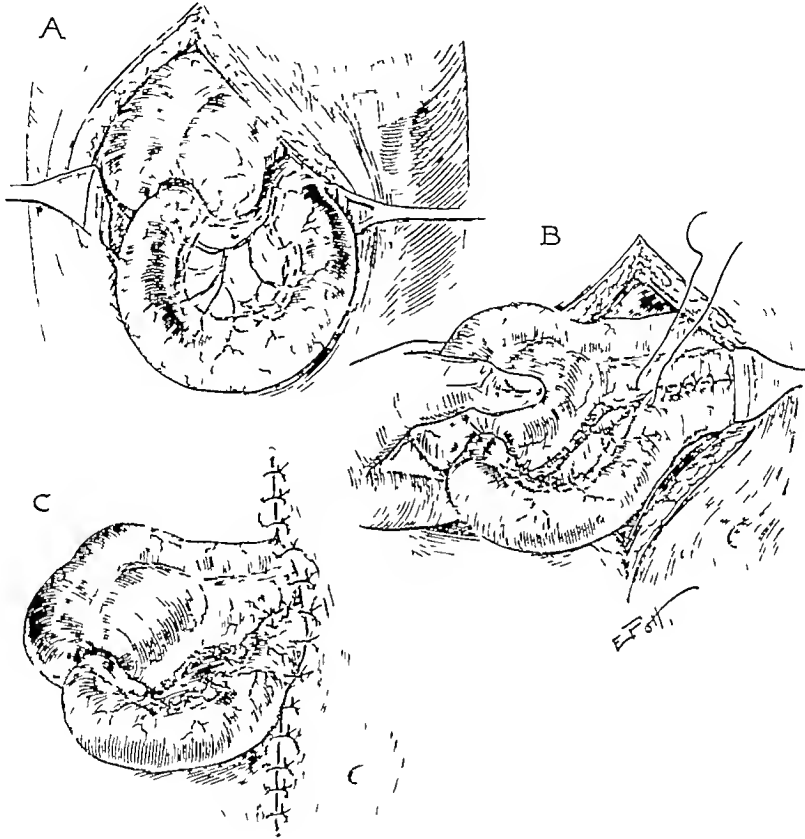

FIGURE 3 Method for Aseptic Resection of Gangrenous or Irreducible Intussusception. A shows a right-rectus-muscle incision for ileocolic intussusception (the mesentery and mesocolon will be divided along the dotted line), B the bowel freed from its mesenteric attachments, the limbs of the ileum and colon being joined by interrupted fine silk sutures, which must not pierce the mucosa, and C the intussusception being exteriorized, and the abdominal wound closed around the limbs of the ileum and colon.

days, and then the enterostomy can be closed within six or seven days of the initial operation.

In this series 14 cases in all have been treated by this method, with 11 recoveries—a mortality of 23 per cent. Eleven of these patients have been treated in the last nine years, with recovery in 10—a present-day mortality rate of 9 per cent. (The single fatal case in this latter period occurred in a four-month-old baby who, through a misunderstanding, failed to receive a postoperative blood transfusion and died in shock four hours later.) The successful resections were done in children aged three days, four months, six months, eight months,

ing. It is well to explain that all Dennis's patients were operated upon by himself—a master in intestinal surgery. In contrast, the resections in our series have been done in some cases by the senior surgeons, but most of them have been performed by the resident staff. There can be little doubt that resection and primary anastomosis is a better form of therapy, provided it is done by one who is constantly practicing intestinal or colonic surgery. However, for the surgeon who is only occasionally dealing with intestinal problems, the method of exteriorization emphasized above will probably give higher recovery rates.

## POSTOPERATIVE CARE

The aftercare of a child with an easily reducible intussusception consists mainly of gastric suction

tion eliminates the hazards of post-anesthesia vomiting and aspiration pneumonia, furthermore, it adds to the child's comfort by keeping the upper in-

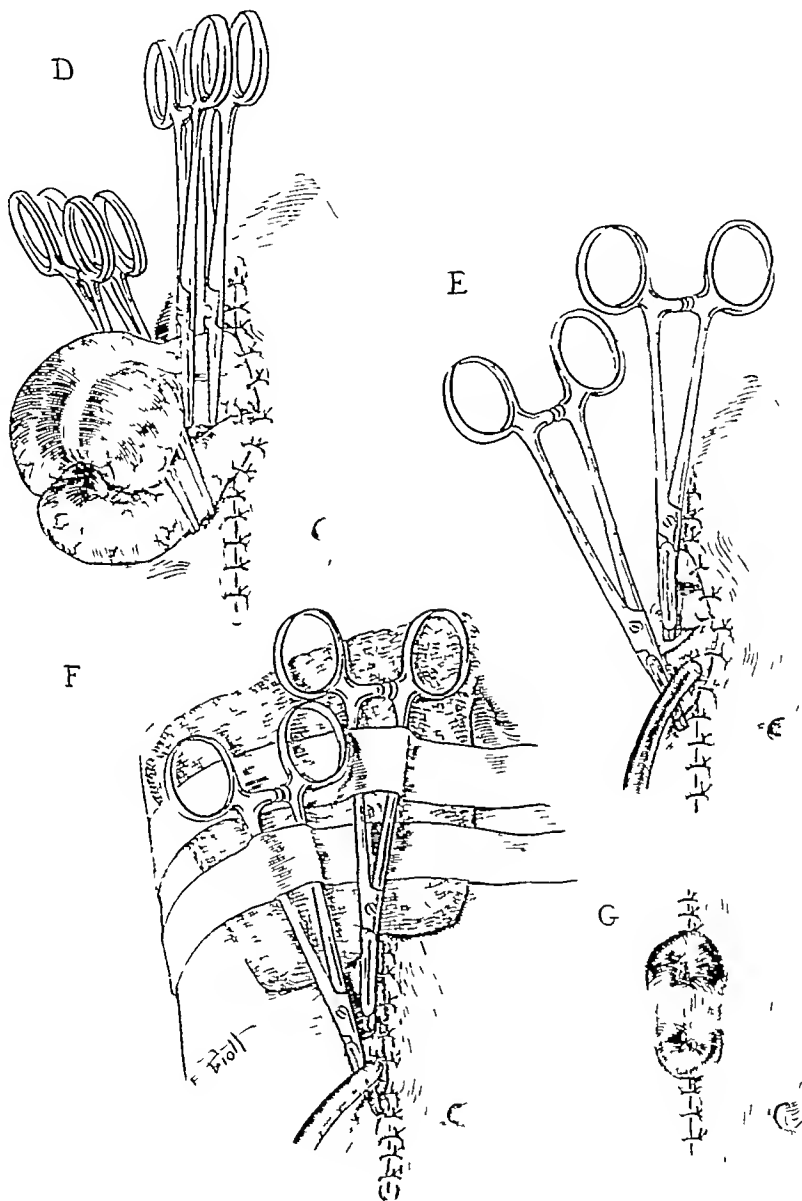

FIGURE 3 (Continued)

D demonstrates removal of intussusception deferred until the abdominal wound is completely closed (appropriate clamps are applied to the two limbs), E intussusception cut away and a catheter inserted into the ileum for immediate and continued decompression of the small intestine. F two clamps left on the limbs to anchor them for several days until the limbs become adherent to the abdominal wall, and G the appearance of the ileostomy-colostomy several days after operation and after removal of the clamps (the septum between the double-barreled spurs can now be cut down, and the remaining opening of the bowel can be turned in without entering the peritoneal cavity).

with an indwelling Levin tube or urethral catheter (in young babies) for twelve to twenty-four hours and the administration of parenteral fluids. Suc-

testinal tract decompressed. After removal of the suction tube, the child is offered sips of clear fluids, followed by more nourishing fluids as tolerated. A

fluid intake of 2 or  $2\frac{1}{2}$  ounces per pound of body weight per twenty-four hours is maintained by intravenous and subcutaneous injection of glucose and saline solutions. Parenterally administered fluids are rarely needed for more than forty-eight hours. By the fourth or fifth day the child can usually take feedings by mouth that easily meet the fluid and caloric requirements.

Successful postoperative care of the child who has had a resection requires more vigorous measures. Careful charting of temperature, pulse and respirations should be done at intervals of fifteen or thirty minutes until the patient is in a stable condition. Blood-pressure determinations in children under two years of age have little practical value. The rate and quality of the pulse are the main indexes of the child's status. An infusion of plasma, or preferably blood, should always be given at the termination of operation, and repeated if the condition of the child requires it. The size of a transfusion is determined by the severity of the blood loss and by the child's hemoglobin or red-cell count. In general, no more than 10 cc of blood per pound of body weight should be given at a time, unless blood loss has been extreme. Even if bleeding has been minimal before or during operation, strangulating obstruction always produces a decrease in the circulating plasma volume, often approaching shock proportions. Hence, repeated plasma (or albumin solution) infusions may be life saving in these critically ill children. Plasma or albumin infusion should rarely be more than 10 cc per pound of body weight, but this may be repeated in a few hours if the circulatory state requires it. Intravenous or subcutaneous injections of amigen solutions greatly aid in supporting nutrition whenever there is a long period of convalescence that is complicated by gastric suction and inadequate, oral, protein intake. The salt content of plasma (and some albumin solutions) must be borne in mind, if an excess of salt is given by injection of too much of these fluids, the baby may become edematous. If the postoperative period is prolonged for any reason, it is essential to study the plasma levels of chloride, protein and carbon dioxide combining power to guide intelligently the proper parenteral fluid or blood therapy.

Following the work of Fine and his associates,<sup>4</sup> we have frequently used high-concentration oxygen

tents for the more severely ill children, with excellent results. To keep oxygen levels at 90 to 95 per cent it is necessary to have a very tightly closed chamber, and to avoid frequent openings of the tent.

Chemotherapy has little place in the treatment of the routine case in which there is an easily reducible intussusception. It is of great value in patients who are seriously ill from peritonitis or from aspiration pneumonia.

#### SUMMARY

A series of 610 cases of intussusception treated at the Children's Hospital in Boston is presented. The etiology in 95 per cent of the cases is unknown. Intussusception is characterized by sudden onset of paroxysmal abdominal pain, vomiting, bloody stools and a palpable abdominal mass, the condition occurring usually in a well nourished baby. Roentgenologic examination by barium enema may aid in making the diagnosis in atypical cases, but it is not necessary in the majority of cases, in which the history and physical findings are sufficient to establish the proper diagnosis.

The optimum treatment of intussusception is by surgical reduction of the intussusception after rapid but important preoperative preparation. If resection is necessary, exteriorization is the method of choice, since this rigidly prevents contamination or soiling of the peritoneal cavity. Postoperative care includes the use of gastric suction, transfusion of blood or plasma, infusion of glucose or saline solution and in some cases institution of chemotherapy and placement of the child in a high-concentration oxygen tent.

The mortality rates for intussusception have improved steadily, in the last few years the mortality has been reduced to 2.7 per cent.

TRENDS IN PULMONARY TUBERCULOSIS DURING FIFTY YEARS AT RUTLAND STATE SANATORIUM\*

MACEY KRONICK, M D †

RUTLAND, MASSACHUSETTS

THIS was the first state sanatorium for the treatment of pulmonary tuberculosis to be established in the United States. The project was planned in 1895 and the opening took place fifty years ago, in 1898<sup>1</sup>. Many similar institutions were modeled after this one, which was considered quite an achievement at the time.

In a review of the yearly reports<sup>2</sup> and records of the half century many interesting facts bring out certain trends in pulmonary tuberculosis, most of which apply to this sanatorium but some of which may be found elsewhere in the country.

ADMISSIONS

During the fifty-year period, this sanatorium admitted 21,304 patients. In the first decade, emphasis was placed on selecting patients who had early or incipient tuberculosis. As a policy "patients were given a trial of three or four weeks,

TABLE 1 Percentage of Patients in Various Stages of Tuberculosis Admitted to Rutland State Sanatorium\*

YEAR	MINIMAL CASES %	MODERATELY ADVANCED CASES %	FAR- ADVANCED CASES %
1898	50.0	38.2	11.5
1907†	39.0	42.0	19.0
1917	40.8	43.8	15.0
1927	12.7	33.2	49.4
1937	11.4	31.2	52.6
1947	7.0	21.0	60.5

\*The remainder of each group up to 100 per cent of the total are unclassified.

†This was the year when the cases were tabulated on the classification adopted by the National Association for the Study and Prevention of Tuberculosis. The Rutland classification used (1898-1906) was similar in most respects.

if found to have more lung trouble than could be expected to yield readily to treatment, they were asked to give up their places to those whose chances of recovery seemed to be more hopeful." Patients who resided in the Sanatorium for less than a month were classified as "not considered." In 1906, of the 1139 discharged during the year, 198 remained only about one month. During the same year the following record was made:

This institution was established by the State on the theory that incipient pulmonary tuberculosis is a curable disease. Its history, up to this time, has confirmed the theory. But the sanatorium has been so enlarged (from the original 170 to 260 beds) that not enough incipient cases apply to fill it. At present not more than one third of the patients are strictly in the incipient stage.

\*Presented at the fall meeting of the American Trudeau Society (Eastern Section) and the fiftyth anniversary meeting of the Rutland State Sanatorium, Rutland, Massachusetts, October 15, 1948.

†Assistant physician, Rutland State Sanatorium.

In 1906, of the cases under treatment 36 per cent were classified as incipient, 41 per cent as moderately advanced, and 21 per cent as advanced. Since the methods of diagnosis then were not so precise — x-ray study being used seldom if at all prior to 1919, and reliance being placed on the physical

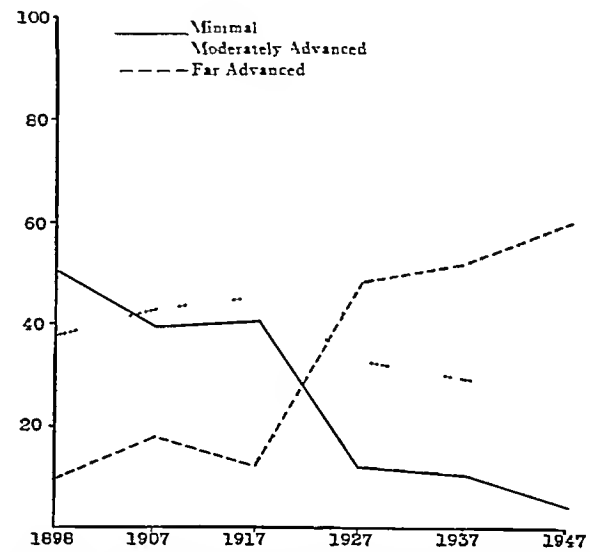

FIGURE 1 Percentages of Patients Admitted in Different Stages of Tuberculosis, Rutland State Sanatorium (1898-1947)

examination, which was of questionable value in accurately diagnosing and classifying minimal cases — it became evident within the first ten-year period that moderately advanced and advanced cases would have to receive more consideration. The changes that occurred in the last twenty-five years are striking compared to those of the first twenty-five years (Table 1). The marked increase in far advanced cases is evident in Figure 1. From 1899 to 1906, of the total number of applicants only 46 to 55 per cent were admitted each year. Forty-five per cent or more were rejected as too far advanced. Minimal cases in 1917 constituted 40.8 per cent of all patients and far-advanced cases 13 per cent, by contrast, in 1947 the minimal cases were only 7 per cent, whereas those in the far-advanced stage made up 60.5 per cent, and moderately advanced cases were 21 per cent, making a total of almost 82 per cent in the advanced stages. The noticeable decrease in the number of admissions (Table 3) began in 1911, by which time three other state sana-

fluid intake of 2 or  $2\frac{1}{2}$  ounces per pound of body weight per twenty-four hours is maintained by intravenous and subcutaneous injection of glucose and saline solutions. Parenterally administered fluids are rarely needed for more than forty-eight hours. By the fourth or fifth day the child can usually take feedings by mouth that easily meet the fluid and caloric requirements.

Successful postoperative care of the child who has had a resection requires more vigorous measures. Careful charting of temperature, pulse and respirations should be done at intervals of fifteen or thirty minutes until the patient is in a stable condition. Blood-pressure determinations in children under two years of age have little practical value. The rate and quality of the pulse are the main indexes of the child's status. An infusion of plasma, or preferably blood, should always be given at the termination of operation, and repeated if the condition of the child requires it. The size of a transfusion is determined by the severity of the blood loss and by the child's hemoglobin or red-cell count. In general, no more than 10 cc of blood per pound of body weight should be given at a time, unless blood loss has been extreme. Even if bleeding has been minimal before or during operation, strangulating obstruction always produces a decrease in the circulating plasma volume, often approaching shock proportions. Hence, repeated plasma (or albumin solution) infusions may be life saving in these critically ill children. Plasma or albumin infusion should rarely be more than 10 cc per pound of body weight, but this may be repeated in a few hours if the circulatory state requires it. Intravenous or subcutaneous injections of amigen solutions greatly aid in supporting nutrition whenever there is a long period of convalescence that is complicated by gastric suction and inadequate, oral, protein intake. The salt content of plasma (and some albumin solutions) must be borne in mind, if an excess of salt is given by injection of too much of these fluids, the baby may become edematous. If the postoperative period is prolonged for any reason, it is essential to study the plasma levels of chloride, protein and carbon dioxide combining power to guide intelligently the proper parenteral fluid or blood therapy.

Following the work of Fine and his associates,<sup>4</sup> we have frequently used high-concentration oxygen

tents for the more severely ill children, with excellent results. To keep oxygen levels at 90 to 95 per cent it is necessary to have a very tightly closed chamber, and to avoid frequent openings of the tent.

Chemotherapy has little place in the treatment of the routine case in which there is an easily reducible intussusception. It is of great value in patients who are seriously ill from peritonitis or from aspiration pneumonia.

### SUMMARY

A series of 610 cases of intussusception treated at the Children's Hospital in Boston is presented. The etiology in 95 per cent of the cases is unknown. Intussusception is characterized by sudden onset of paroxysmal abdominal pain, vomiting, bloody stools and a palpable abdominal mass, the condition occurring usually in a well nourished baby. Roentgenologic examination by barium enema may aid in making the diagnosis in atypical cases, but it is not necessary in the majority of cases, in which the history and physical findings are sufficient to establish the proper diagnosis.

The optimum treatment of intussusception is by surgical reduction of the intussusception after rapid but important preoperative preparation. If resection is necessary, exteriorization is the method of choice, since this rigidly prevents contamination or soiling of the peritoneal cavity. Postoperative care includes the use of gastric suction, transfusion of blood or plasma, infusion of glucose or saline solution and in some cases institution of chemotherapy and placement of the child in a high-concentration oxygen tent.

The mortality rates for intussusception have improved steadily, in the last few years the mortality has been reduced to 2.7 per cent.

charges according to their classification in Table 4, one is struck by the definite decrease, in the past thirty years, of the "quiescent" group and by the increase in the combined percentages of "unimproved" and "dead." This is a natural consequence of the steadily increasing number of older patients and those with more advanced cases admitted, especially in the past decade. Another reason is that more deaths are occurring in sanatoriums, and

dropped to 36.4 in 1946, and a similar decrease occurred in the Commonwealth, it is closely paralleled by the death rate from respiratory forms of tuberculosis in Massachusetts, which decreased from 185 per 100,000 population in 1900 to 32.5 in 1947 (Fig 3). Except for a slight increase in both state and national death rates during the influenza epidemic of 1918 the decline was steady until 1939. Since then the national death rate has continued to

fewer in the community, in 1947, 795 of the 1583 deaths in Massachusetts were in sanatoriums.

Although the deaths from tuberculosis in this sanatorium have shown an increase, particularly in recent years, the death rates due to tuberculosis in the Commonwealth of Massachusetts and in the United States are definitely on the wane (Table 5). The national death rate of over 194 per 100,000 population in 1900 (all forms of tuberculosis)

fall but in Massachusetts, except for a 12 per cent increase in death rate from pulmonary tuberculosis in 1943 over the preceding year, there was no important change until 1947, when a new low record was reached.

#### LABORATORY FINDINGS

Direct smears from the sputum were used for the first thirty-five years. Concentrations were

toriums — Lakeville, North Reading and Westfield — were opened to receive tuberculous patients. Again, in 1936, there was a further decrease owing to the opening of the Worcester County and Middlesex County sanatoriums.

In 1911 Massachusetts had 1200 beds available in sanatoriums for tuberculosis. The number had expanded from a little more than 200 in 1900, and reached 3600 in 1928 and 4736 in 1938. The number in 1946 was 4471.<sup>3</sup> The slight decrease in the number of beds in recent years is attributable to the closing of private and municipal sanatoriums. The ratio of the number of beds to deaths has been considered satisfactory if it approximated 2.5:1. In 1928 it was 1.3:1, in 1938, 3:1, and in 1947, 2.8:1.

In 1925 only 35 per cent of the patients who had reported cases of tuberculosis in Massachusetts applied for hospital treatment, this increased to

55 per cent by 1929 and to 65 per cent by 1935 and is still higher at present.

The survey of the ages of all patients admitted during the half century shows that the minimum age for admission was fourteen years, which was later changed to seventeen years. During the first forty years the average age ranged from twenty-eight to thirty-three years, but from 1937 to 1947 many more of the older age group were among the admissions and the average age in 1947 was forty and two-thirds years. Table 2 presents the percentages of patients in different age groups admitted, and Figure 2 shows the decrease in patients under the age of forty with the proportionate increase in patients above that age especially during the past ten years. For the first time in fifty years, the number of patients over the age of forty now exceeds 50 per cent of all patients admitted to the sanatorium. That active tuberculosis occurs in older persons of the community with greater frequency makes it an important diagnosis to keep in mind not only because of itself but also as a differentiation from carcinoma, bronchiectasis, lung abscess and other pulmonary lesions in such patients

## DISCHARGES

Classification on discharge has changed very little during the fifty-year period. In the Rutland system of nomenclature (1899-1905) the words "apparently cured" and "arrested" were used synonymously. Either or both terms expressed practically the same idea that "apparently cured" represents in the national system except that the three-month period was not required. The official nomenclature

†Fourteen months

established by the National Tuberculosis Association at Washington in May, 1905, was adopted here in 1907. From 1899 to 1910, about 90 per cent of all patients discharged were classified as improved, arrested or apparently cured, and less than 10 per cent as not improved (including deaths). In 1911 there was a sharp increase in the number of deaths (Table 3), which was attributed to the larger number of patients with more advanced cases admitted during the preceding year. In looking over the dis-

egg-nogs, and the average caloric intake was between 3500 and 5000 per day. For the last twenty years a more reasonable diet has been used consisting of 250 gm of carbohydrate, 100 gm of protein and 100 gm of fat, giving a total of 2300 calories. The omission of lunches between meals resulted in a reduction of gastrointestinal disturbances and of food complaints by patients. These patients gained weight faster than with overfeeding, and the change

smaller and more frequent. Careful judgment of the indications for starting as well as for discontinuing treatment<sup>4</sup> has been exercised, and the progress and status of the collapsed lung observed frequently by fluoroscopy and x-ray examination. The earlier experience and results with pneumothorax here were reviewed by Laroche<sup>5</sup> and Nadeau.<sup>6</sup> A total of 4236 patients have received approximately 83,000 treatments from 1927 through 1947. During this time 2176 patients, representing 37.7 per cent of the 5776 patients admitted for pulmonary tuberculosis, were started on pneumo-

probably represents one of the significant improvements in treatment. In tuberculous enteritis a bland, low-roughage diet has been substituted and supplemented with cod liver oil and tomato juice since 1929. This regime, together with ultraviolet radiation to the abdomen, gives considerable relief. Tuberculin and autogenous vaccines were used about 1910, but not extensively, and were abandoned within the next few years.

From 1927 to the present time more active measures of treatment have been carried out as listed in Table 6. As early as 1911 pneumothorax was used in several cases. During the early years it was reserved mainly for advanced cases that did not respond to rest alone, for hemorrhage and for bilateral lesions if one side appeared to be not too active or extensively involved. Large refills of nitrogen at comparatively long intervals were usually given for a year or so. Since 1927 pneumothorax has been used more intensively, nitrogen has been replaced by filtered air, and refills are

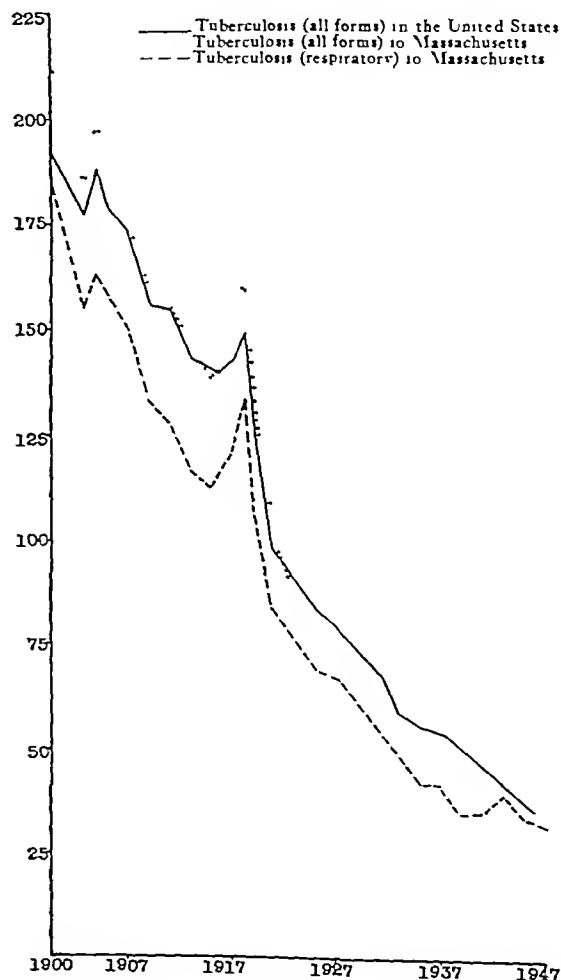

FIGURE 3 Death Rates per 100,000 Estimated Population, 1900-1947

thorax, and of these 70.3 per cent were successful and 29.7 per cent unsuccessful (Table 6). Dufault's graph showing trends of active treatment from 1927 to 1938 has been extended through 1947 (Fig. 4). The curve of total pneumothoraces initiated (in terms of percentage of admissions) during each of these twenty-one years demonstrates a steady rise from 5.8 per cent of all admissions in 1927 to the peak of 61.3 per cent in 1939. From then

begun in 1932. The culture method, started about 1936, has been used more frequently than concentrations since 1940. The original culture medium consisted of a slice of potato to which was added dye, glycerin and water. Soon this was replaced by a modified Pinner medium with a potato, water and egg base. More recently the Lowenstein medium has been substituted. The cultures may become positive in two weeks but may also require as much as six weeks to show growth. After a positive reaction has been obtained, smears are done monthly, when they turn negative, cultures are done at six-week intervals. If these are negative, or if no suitable specimen of sputum is obtained, gastric contents are examined by smear, concentration test and guinea-pig inoculation. The animals are kept for eight weeks. These methods have increased the number of "positives." When only smears from sputum were examined up to 1932, the reactions of only 67.4 per cent of all patients

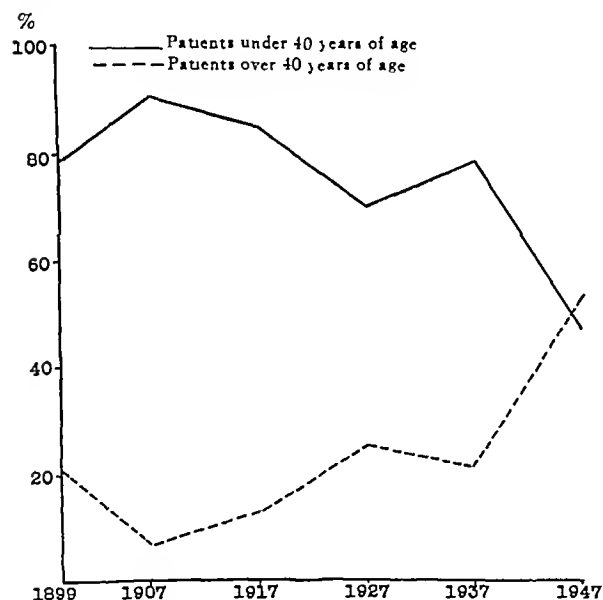

FIGURE 2 Percentages of Patients Admitted over and under Forty Years of Age

were found positive, whereas 94.5 per cent are now positive on sputum or gastric contents.

Complete blood examinations, including differential count and sedimentation rate (Rourke and Ernstene), are routinely carried out every two months and, like comparative x-ray films, are of considerable help in following the patient's progress.

An x-ray machine was installed at the sanatorium in 1919, and from a few hundred films per year, the department now averages three or four thousand

#### TREATMENT

Since the beginning of the century several changes have appeared in the treatment. The importance of fresh air was early recognized. Data concerning climatic conditions including rainfall, temperature,

humidity, sunshine and so forth were recorded during the first decade, but less attention was focused upon these factors thereafter. No longer are patients exposed to cold beyond physical comfort.

For several years, bed rest was prescribed only in the event of high temperatures or hemoptysis. Patients enjoyed moderate activity mingled with

probably represents one of the significant improvements in treatment. In tuberculous enteritis a bland, low-roughage diet has been substituted and supplemented with cod liver oil and tomato juice since 1929. This regime, together with ultraviolet radiation to the abdomen, gives considerable relief. Tuberculin and autogenous vaccines were used about 1910, but not extensively, and were abandoned within the next few years.

From 1927 to the present time more active measures of treatment have been carried out as listed in Table 6. As early as 1911 pneumothorax was used in several cases. During the early years it was reserved mainly for advanced cases that did not respond to rest alone, for hemorrhage and for bilateral lesions if one side appeared to be not too active or extensively involved. Large refills of nitrogen at comparatively long intervals were usually given for a year or so. Since 1927 pneumothorax has been used more intensively; nitrogen has been replaced by filtered air, and refills are

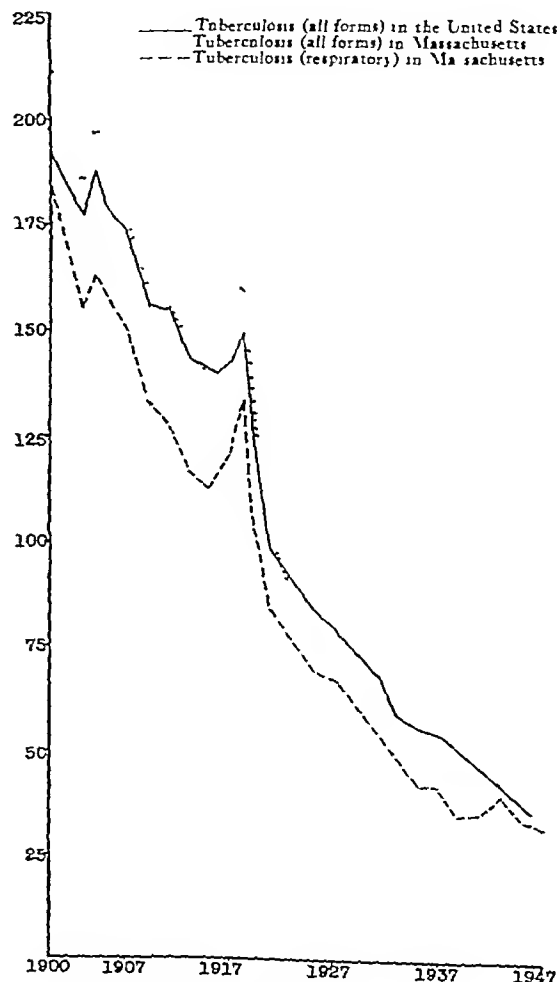

FIGURE 3 Death Rates per 100,000 Estimated Population, 1900-1947

thorax, and of these 70.3 per cent were successful and 29.7 per cent unsuccessful (Table 6). Dufault's graph showing trends of active treatment from 1927 to 1938 has been extended through 1947 (Fig. 4). The curve of total pneumothoraces initiated (in terms of percentage of admissions) during each of these twenty-one years demonstrates a steady rise from 5.8 per cent of all admissions in 1927 to the peak of 61.3 per cent in 1939. From then

begun in 1932 The culture method, started about 1936, has been used more frequently than concentrations since 1940 The original culture medium consisted of a slice of potato to which was added dye, glycerin and water Soon this was replaced by a modified Pinner medium with a potato, water and egg base More recently the Lowenstein medium has been substituted The cultures may become positive in two weeks but may also require as much as six weeks to show growth After a positive reaction has been obtained, smears are done monthly, when they turn negative, cultures are done at six-week intervals If these are negative, or if no suitable specimen of sputum is obtained, gastric contents are examined by smear, concentration test and guinea-pig inoculation The animals are kept for eight weeks These methods have increased the number of "positives" When only smears from sputum were examined up to 1932, the reactions of only 67.4 per cent of all patients

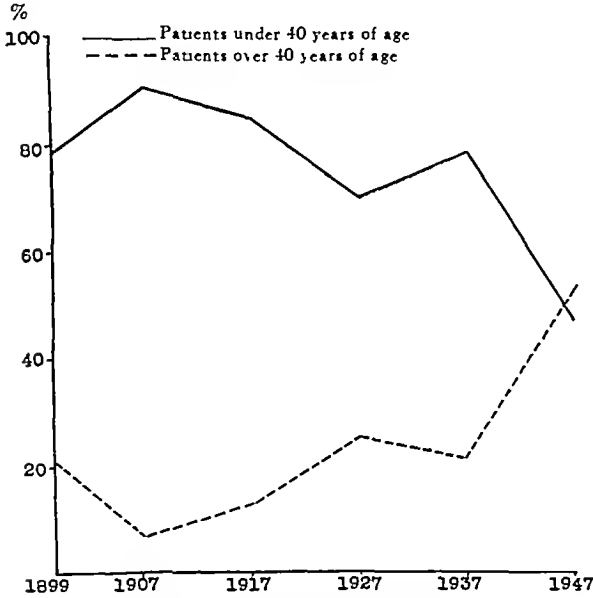

FIGURE 2 Percentages of Patients Admitted over and under Forty Years of Age

were found positive, whereas 94.5 per cent are now positive on sputum or gastric contents

Complete blood examinations, including differential count and sedimentation rate (Rourke and Ernstone), are routinely carried out every two months and, like comparative x-ray films, are of considerable help in following the patient's progress

An x-ray machine was installed at the sanatorium in 1919, and from a few hundred films per year, the department now averages three or four thousand

TREATMENT

Since the beginning of the century several changes have appeared in the treatment The importance of fresh air was early recognized Data concerning climatic conditions including rainfall, temperature,

humidity, sunshine and so forth were recorded during the first decade, but less attention was focused upon these factors thereafter No longer are patients exposed to cold beyond physical comfort

For several years, bed rest was prescribed only in the event of high temperatures or hemoptysis Patients enjoyed moderate activity mingled with

rest periods in sitting or reclining positions while fully clothed Gradually, however, bed rest during the period of clinical activity became the rule, and graduated exercise followed when clinical and laboratory evidence indicated that the process had subsided

In earlier years overfeeding was the rule, in addition to large meals there were lunches of milk and

## DISCUSSION

At this sanatorium during the past half century a few trends seem evident. An important one is the advanced stage of the disease in patients admitted and the older ages of these patients. This combination accounts in large measure for the increasing death rate, the decreasing number of patients suitable for collapse therapy (pneumothorax and thoracoplasty) and the prolonged length of residence. From an average stay of four to six months at the early part of the century, the length of residence increased to an average of six to ten months in the years 1910 to 1927, and for the last twenty years has ranged from ten to eighteen months. Another factor influencing length of residence has been the change in methods of treatment. There is little doubt that since the first thirty years, when almost 100 per cent of patients received only the basic rest treatment, many lives have been saved or prolonged by more active therapeutic measures. During the last twenty years, approximately 1 out of every 2 patients received rest alone, in 1 out of every 3 pneumothorax was attempted, 1 out of every 4 had successful pneumothorax, almost half the patients with successful pneumothoraces had pneumonolysis, 1 out of every 16 patients had thoracoplasty, 1 out of every 15 had phrenic-nerve surgery, and 1 out of every 60 received extrapleural pneumothorax, pneumoperitoneum, oleothorax, lobectomy or pneumonectomy. Our experience with streptomycin is still limited but agrees with the reports in the literature regarding its beneficial effects in selected cases and may prove to be

an important supplement to our other forms of therapy.

In the community the clinically significant trend in pulmonary tuberculosis that has taken place during the past fifty years is the definite and steady decline in death rates. A contributing factor in reducing the case rates and death rates, in addition to our methods of therapy, may be the isolation of active cases from the general population. In Massachusetts the case rate is now one fourth that in 1910, and the death rate only one sixth of what it was in 1900. Strides have been made in the medical and surgical methods of collapsing the lung and the closing of cavities. We seem to be approaching the ideal agent that might, by its bactericidal or bacteriostatic action in early cases, completely change our prolonged methods of treatment.

on there was a progressive decline (except for 1943) until only 24.8 per cent in 1946 and 18.0 per cent in 1947 were started on pneumothorax.

Intrapleural pneumonolysis was carried out 647 times between 1927 and 1947. This comprises 42.4 per cent of all the patients who had successful pneumothorax. With conservative approach and careful technic the number of complications, including effusions, hemothorax and empyemas, has decreased considerably.

Bronchoscopy has assumed an important and integral role in diagnostic if not therapeutic aid in

valuable measure for suitable cases. Its application, however, has been limited. Our first 2 cases were done in 1927, and a review of the entire group from 1927 to 1938 was presented by Dufault.<sup>7</sup> A further report to bring the study to date is being prepared.<sup>8</sup> In the extension of Dufault's chart to the present (Fig. 4) it is evident that the curve reached its height in 1939, when 16.5 per cent of patients admitted came to thoracoplasty, but the incidence has dropped since then to 5.6 per cent in 1946 and 3.3 per cent in 1947. During the last twenty-one years 366 of these patients, representing

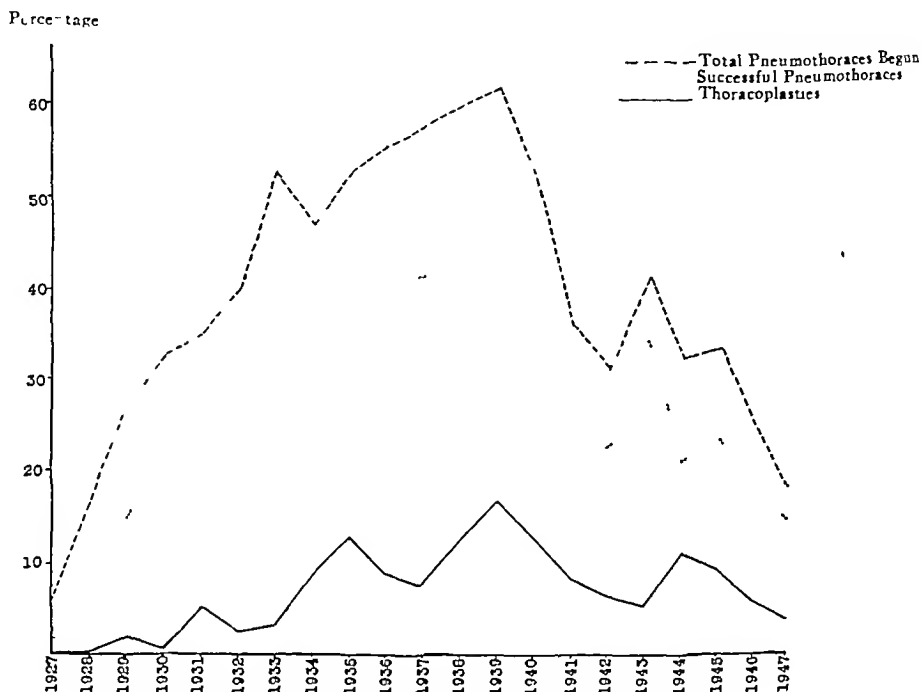

FIGURE 4 Trends of Active Treatment, 1927-1947, Inclusive (Expressed as Percentages of Admissions)

pulmonary tuberculosis. The presence of endobronchial disease may be demonstrable in more than 50 per cent of such pathologic conditions as ulceration, edema, stenosis and strictures, and may explain the persistence of positive sputum, the presence of atelectasis and of the other lesions the pathogenesis of which is obscure even with serial x-ray films and clinical data. In the 1927-1947 period, 1294 bronchoscopies were performed, mostly for diagnostic purposes. Occasionally, a patient with bronchiectasis received repeated aspirations, and in earlier years many ulcers were treated by chemical and thermal coagulation and cauterization. In recent years fewer cases have been treated actively. Bronchoscopy has been a routine preoperative procedure for all thoracoplasties during the last few years.

Thoracoplasty, as well as pneumothorax, has withstood the test of time and experience as a

6.3 per cent of those admitted, received thoracoplasty.

Extirpative surgery has been found beneficial in a small selected group. Fifteen patients had lobectomies from 1939 through 1947, and 19 patients had pneumonectomies from 1940 through 1947. Eighteen of the latter were incorporated in the 36 cases reported by Sweet.<sup>9</sup>

Other forms of active treatment have passed their peak and are now applied infrequently. Phrenic-nerve surgery, used in 381 cases in 1929-1938, was carried out in only 14 cases during the last nine years. Oleothorax, utilized in 40 cases between 1931 and 1939, has been practically abandoned. Extrapleural pneumothorax had its limited role in 1938 and 1939 with 19 cases, but has not been used since. Pneumoperitoneum has been administered to a few patients.

culous empyemas, making a total of 26 (Table 8). In 19 cases the empyema was accompanied by pulmonary tuberculosis, as evidenced by the positive sputum. That 14, or 56 per cent of them are living and well in 1947 is an agreeable surprise. As they were all operated on between the years 1931 and 1942, they have now been well from five to seventeen years. The patients with tuberculous

culosis. The current use of streptomycin before and after the operation may eliminate most postoperative deaths due to pneumonic and miliary spreads.

#### SUMMARY

Thoracoplasty was performed in 362 patients at the Rutland State Sanatorium between 1927 and 1946, inclusive.

TABLE 8 *Empyemas*

TYPE OF EMPYEMA	SPUTUM POSITIVE	SPUTUM NEGATIVE	PATIENTS WELL		PATIENTS DEAD		TOTAL

\*1 unknown

empyema did much better than those with mixed empyema.

#### DEATHS

Eighteen patients died postoperatively — that is, within an arbitrary time limit of two months after the operation. The time of death for the others ranged between one and nineteen years. 5 patients dying within one year, 9 after one year, 22 after two years, 19 after five years and 8 after ten years. Five deaths are attributable to heart disease, in no way related to tuberculosis so far as could be ascertained. One death was due to an accident, and another followed a cholecystectomy years after discharge. It was not always possible to determine precisely the cause of death in every case but it is assumed that it resulted from progressive tuber-

culosis. The patients who received thoracoplasty represent 63 per cent of the 5597 tuberculous persons admitted during the same period.

The clinical indications are the same today as they were twenty years ago.

As sanatorium patients are noticeably older and sicker than they were in the past, the percentage of thoracoplasties is likely to decrease rather than increase if the present trends continue.

The immediate and late results of thoracoplasty for pulmonary tuberculosis and for tuberculous and mixed empyemas are tabulated.

The 86 deaths are briefly studied.

Thoracoplasty is now a well standardized and time-tested procedure which, in properly selected cases, gives excellent results.

All thoracoplasties were done at the Massachusetts General Hospital on the services of Dr. Edward D. Churchill and Dr. Richard H. Sweet.

are well, 12 are ill, 47 are dead, and in 14 the results are unknown

LATE RESULTS

Table 7 shows the present status of 362 patients over a period of twenty years. As much of the follow-up observation was made by correspondence, it would have been too difficult to evaluate exactly

to the "well," there is a survival rate of approximately 70 per cent. Close to 90 per cent (87 per cent) of these patients showed demonstrable cavitation. The others had persistently positive sputum, with fibrotic lesions or else suffered from an empyema. Untreated cavernous pulmonary tuberculosis, as well as tuberculous and mixed empyema, ends fatally in 90 per cent of cases within a few

the condition of the patient as arrested, apparently arrested, quiescent and so forth, according to the National Tuberculosis Association diagnostic standards. This tabulation is based only on one practical point: Is the patient well enough to work or is he not? If the patient is in the sanatorium or at home, but invalid or semi-invalid, he is listed

years. Allowing for a 10 per cent survival without surgery, one is left with a 50 per cent salvage to the credit of thoracoplasty. If only the period from 1927 to 1936 is considered, this salvage has already lasted from ten to twenty years. Furthermore, some of the deaths occurring over such a span of years are from causes other than tuberculosis.

TABLE 7 Results of Thoracoplasties over a Period of Twenty Years

under the heading "ill." Five or six of these, operated on at the end of 1946, are completing their cure and will soon be counted among the "well."

The most striking features of Table 7 are the almost equal proportions of patients well and working for the two ten-year periods: 59.7 per cent and 62 per cent, giving a combined rate of 61.3 per cent for the entire twenty years. If the "ill" are added

These deaths discounted, the proportion of survivals would reach about 65 per cent. These are very satisfying results.

EMPHYEMAS

The patients who received thoracoplasty for empyema fared almost as well as those with pulmonary tuberculosis. There were 16 mixed and 10 tuber-

Even the post-mortem findings are of little help since an unknown number of patients may presumably recover, leaving little or no trace, whereas other cases have undoubtedly been confused with tuberculosis. The disease may actually be commoner than has been suspected.

Although sarcoidosis manifests itself at any age, most of the cases occur in the period from fifteen to fifty, with a broad indefinite peak of incidence in the third and fourth decades. Kissmeyer<sup>5</sup> notes that more than half of 200 patients presented evidence of the disease before the age of thirty and two thirds before forty, and of Reisner's 35 cases more than two thirds were under thirty at onset.<sup>38</sup> Such figures are, of course, minimal since it is often impossible to be certain when the disease actually began. Of over 700 cases culled from the literature and his own experience, Gravesen<sup>5</sup> found only 19 under the age of ten and 30 over the age of sixty. Cases have been described in infants of three weeks,<sup>25</sup> three months<sup>39</sup> and twenty-five months,<sup>40</sup> and in persons of seventy<sup>26</sup> and eighty years.<sup>9</sup> Most authors record either no special sex incidence<sup>8, 41, 42</sup> or a predominance in the female of 2 to 1 or more.<sup>10, 24, 29, 35, 43, 44</sup>

The frequency of the disease in the white race, and especially in the Nordic groups, is clearly indicated by the numerous reports emanating from the Scandinavian countries. In this country, however, an unusually high incidence has been noted among Negroes.<sup>4, 35, 45-47</sup> A number of these reports come from the South, but Negroes also constitute 86.0 and 28.5 per cent, respectively, of two groups reported from New York City,<sup>38, 46</sup> 80 per cent of one from Philadelphia,<sup>41</sup> 42 per cent of another from San Francisco,<sup>4</sup> and over 50 per cent of an Army hospital group.<sup>47</sup> All these figures are considerably higher than the proportion of Negroes in the local populations. In Boston, at the Massachusetts General Hospital, Negroes have constituted only about 10 per cent of patients with sarcoidosis. Cases have been reported in an American Indian<sup>42</sup> and an Algerian Berber.<sup>45</sup>

The disease has been seen in siblings on a number of occasions.<sup>48-58</sup> Sella and Berger<sup>49</sup> describe a family of 7 siblings, 5 of whom had sarcoidosis proved by biopsy. Robinson and Hahn<sup>57</sup> note its occurrence in two unrelated Negro families, in one family at least 2 of 3 siblings were affected, whereas in the other, which included 10 siblings, a positive diagnosis was established in 3, and a probable or possible diagnosis in 3 others.

#### *Pathology and Pathogenesis*

The appearance of the typical sarcoid lesion varies little with the tissue in which it is found. It consists of a mass of noncaseating "tubercles" composed almost entirely of large, pale, epithelioid cells with little or no surrounding collar of lymphocytes. The granulomas tend to occur in large numbers, often cluster about small blood vessels or lymphatics and may diffusely replace an involved tissue, such as

lymph node or spleen, with a mass of closely packed lesions all more or less in the same stage of development. Even under such conditions the individual granulomas rarely tend to become confluent; reticulum or collagen stains may reveal discrete lesions in an apparently fused mass of fibrous tissue. Silver impregnation also discloses a fine network of reticulum penetrating the granulomas and tending to surround individual cells or groups of cells.

It is now known that the histologic appearance of the lesion, even in clinically typical cases, is subject to some variation. Moderate numbers of lymphocytes may be scattered among the epithelioid cells, but neutrophils and eosinophils are practically never present. Giant cells are frequently not prominent, but their rarity is not a dependable diagnostic point as was once thought. Such cells actually vary considerably in number from case to case and may be very large and numerous, many are of the typical Langhans variety, but large cells of the foreign-body type predominate in some cases. Both giant cells and epithelioid cells may contain vacuoles. Even the characteristic absence of necrosis is not constant, small necrotic foci in the central portions of the lesions have often been described and are no longer considered incompatible with the diagnosis.

Inclusion bodies of several varieties have been found usually within or in association with giant cells of the foreign-body type. All of them appear to be nonspecific and are without known significance, but it is of interest that they have not been observed in association with unequivocally tuberculous lesions in man.<sup>29, 59-61</sup> Radial or asteroid inclusions<sup>61-63</sup> have been described not only in sarcoidosis<sup>64, 65</sup> but also in association with the lesions of leprosy<sup>66</sup> and torulosis<sup>67</sup> and in many foreign-body granulomas.<sup>68</sup> Their nature is still uncertain, though Hirsch<sup>63</sup> concluded from animal experiments that they represented crystallized fat. Doubly contoured or laminated, often deep-staining bodies have been described by Schaumann<sup>63</sup> and others,<sup>59, 67-71</sup> and suggest concentric depositions of amorphous material impregnated with varying amounts of calcium and iron salts on some nucleus of foreign material, possibly remnants of elastic fibers. They seem to occur with greatest frequency, though not exclusively, in the lung. They have also been seen in association with beryllium lesions<sup>72, 73</sup> and were described by Metchnikoff<sup>74</sup> in lesions produced by tubercle bacilli in the African rat. Finally, irregular, often anisotropic particles have been seen. These stain very poorly and sometimes suggest minute fragments of glass or silica. They have, in fact, been described in local sarcoid granulomas developing after trauma by such substances<sup>75, 76</sup> and at times also suggest cotton or similar fibers.

In the material obtained by biopsy at the Massachusetts General Hospital, inclusions of all types have been noted in about 30 per cent of cases. Asteroid bodies have occurred with greatest fre-

## MEDICAL PROGRESS

### SARCOIDOSIS\*

DAVID G. FREIMAN, M.D.†

BOSTON

IN 1899 Boeck<sup>1, 2</sup> published almost simultaneously in Norway and in the United States a report on some apparently rare skin manifestations that have since come to be associated with his name. These dusky blue nodular or infiltrative lesions showed, on histologic examination, an epithelioid structure, which he at first interpreted as sarcoma-like ("sarkoid") and later assumed to be of tuberculous genesis.<sup>3</sup>

Since that time there has been a steadily mounting interest in a disease of which the skin lesions of Boeck are only one of many regional manifestations. An ever-increasing number of case reports have accumulated under a wide and confusing variety of names in turn descriptive, etiologic and eponymic, as a glance at the bibliography will indicate, at least 30 have been listed by Pinner,<sup>4</sup> Gravesen<sup>5</sup> and the numerous other reviewers. Fortunately, however, as the disease has been emerging from its status as a medical curiosity and has become more widely recognized as a fairly well defined entity, most of the earlier designations have been gradually discarded in favor of sarcoidosis (or Boeck's sarcoid) in this country and benign lymphogranulomatosis (or recognizable modifications of Besnier-Boeck-Schaumann's disease) in Europe. All these names leave something to be desired, but it seems best at present to let well enough alone until such time as the true nature of the condition becomes established beyond question.

The early history of the disease has been thoroughly reviewed by Hunter<sup>6</sup> and others<sup>7-10</sup> and will not be repeated here. It is worthy of note, however, that although Boeck appears to have been the first to describe the histologic characteristics of the skin lesions, Hutchinson<sup>11, 12</sup> had already published a clinical description of such a case in 1875, and 2 others in 1898. Besnier,<sup>13</sup> in 1889, and Tenneson,<sup>14</sup> in 1892, had also described lupus pernio, which was later shown to be another skin manifestation of the same disease.<sup>15</sup> The reports following Boeck's indicated that other organic systems could also be affected, so that by 1914 Schaumann<sup>16</sup> was able to postulate a generalized disease primarily affecting the lymphohematopoietic apparatus, and only incidentally the skin. It is only in recent years that such conditions as uveoparotid fever and at least some

cases of the Mikulicz syndrome have come to be recognized as special manifestations of the same disease.<sup>4, 9, 17-19</sup>

### CLINICAL AND PATHOLOGICAL ASPECTS

#### *Incidence*

Sarcoidosis was once considered a rare and unusual curiosity of primary interest to the dermatologist. Since its essentially disseminated character has been recognized, however, and particularly with the widespread use of the chest roentgenogram, the disease has been diagnosed with increasing frequency. A constantly enlarging literature includes reports of well over 1000 cases of this and such related syndromes as uveoparotid fever, and the mounting interest is reflected in numerous monographs and reviews from many countries.<sup>4, 5, 9-17</sup> Cases have been reported from practically every country in Europe, but especially the Scandinavian countries, from Australia, Japan, Latin-America and in increasing numbers from the United States and Canada. The distribution thus seems to be world wide, with at least an apparent predilection for the cooler countries.<sup>9, 10</sup> It is exceedingly difficult, however, to make even an approximation of the actual incidence. Routine fluoroscopy of more than half a million recruits for the Swiss Army revealed 115 provisional cases of sarcoidosis, of these, 67 were finally considered proved, an incidence of 0.13 per thousand.<sup>20</sup> Gravesen,<sup>5</sup> in Denmark, basing his figures on incidence in a tuberculosis sanatorium, arrived at about the same figure, but an unknown number of cases is certain to be overlooked by such methods. At the Massachusetts General Hospital, a diagnosis of sarcoidosis has been made by biopsy about 80 times during the past twenty years. In many of these cases, however, the lesion has been strictly localized, or the clinical data are incomplete or unavailable, so that a diagnosis is warranted in only about 45.<sup>29</sup> In at least 12 other patients lesions consistent with sarcoidosis, unsuspected during life, were accidentally discovered at autopsy. A few of these cases have already been reported.<sup>20-27</sup> All these findings are a very unreliable index of local incidence, however, a fair number of probable cases have never been confirmed by biopsy,<sup>20</sup> and still others have most certainly been overlooked since the course of the disease in many patients is so benign as to escape diagnosis except by accident.

†Instructor in pathology, Tufts College Medical School; assistant pathologist, Massachusetts General Hospital.

perfectly well, or diffuse pulmonary infiltration may be discovered quite by accident on a routine chest film. Often, however, minimal or moderate systemic symptoms are noted. Tiredness, weakness, loss of appetite, loss of weight, joint pains and low-grade fever may be present to a variable degree and may be of such low grade as to be scarcely recognized as symptoms. It is probable that such symptoms correspond with active dissemination of the disease, for they are often noted at times when new localizations are appearing, they usually subside as the disease enters the chronic phase, during which such localizations stabilize or regress, and may recur with the development of new clinical manifestations at a later date.<sup>35</sup>

**Lymph nodes** Involvement of lymph nodes as manifested by palpable or roentgenographic enlargement, is demonstrable in almost every case,<sup>9 35 42 47 95 96</sup> and lesions may be found on histologic section even in nodes not significantly enlarged.<sup>35 95</sup> The intrathoracic nodes appear to be the group most consistently affected, and in some series all<sup>47</sup> or almost all<sup>35 96</sup> cases have shown prominent hilar shadows so interpreted. The increase in size of the paratracheal group of lymph nodes parallels that of the peribronchial group, and although the bifurcation group of nodes is probably enlarged as well, this is difficult to demonstrate radiologically.<sup>47</sup> The enlargement is usually bilateral, as distinct from tuberculosis, which is frequently unilateral, the lymph nodes on the right may, however, be larger and more numerous than those on the left,<sup>43 47</sup> possibly because more are present on this side.<sup>97</sup> The nodes have little tendency to coalesce, a point in keeping with the histologic observation that the sarcoid lesions in lymph nodes show very little tendency to extend beyond the capsule. Even considerable enlargement of the hilar nodes is rarely associated with pressure or other obstructive phenomena, and studies in such cases have revealed complete absence of narrowing of the airway through massive nodes<sup>98</sup> or at most slight narrowing.<sup>47</sup> All these findings provide points of differentiation from the lymphomas or carcinomas, with which such lymph-node enlargement may be confused. Atelectasis has occasionally been reported and attributed to such enlargement.<sup>31 41 43</sup> In such cases, however, involvement of the bronchial mucous membrane with stenosis may be a contributory factor.<sup>29</sup> The esophagus may be displaced or compressed.<sup>47</sup> Vocal-cord paralysis has been described<sup>9 99</sup> but not phrenic-nerve involvement.

Although it is possible that other deep lymph-node groups are involved as frequently as those of the mediastinum, this is for obvious reasons difficult to estimate. Such involvement has been noted at a number of autopsies, however.<sup>69</sup> Palpable peripheral nodes are present in at least half to three fourths of the cases,<sup>35 47</sup> with cervical, axillary and inguinal groups affected about equally, and the epitrochlear

group only slightly less often. The nodes tend to be discrete, firm, freely movable and nontender.

The tonsils are involved in a large percentage of cases. Schaumann<sup>95</sup> found such involvement in all 21 active cases in which they were examined, and Gravesen<sup>5</sup> reports this in 45 of 70 cases in which the diagnosis was certain.

**Spleen** This organ is probably affected far more often than is evident from clinical reports. Considerable splenic enlargement is necessary before the organ becomes palpable, and extensive involvement has been demonstrable histologically in organs weighing 200 gm or less.<sup>64 80 100</sup> In a series of 29 autopsied cases from the literature,<sup>64</sup> splenic lesions were noted in 21 — the same frequency, incidentally, with which lymph-node involvement was reported in this group.

Marked splenomegaly may occur, some organs weighing well over a kilogram.<sup>101 102</sup> Such splenic enlargement has occasionally been the only detectable evidence of the disease, and in a number of cases removal of the organ for Banti's disease has revealed the sarcoid lesions. Such patients may complain of discomfort or a dragging sensation in the left upper quadrant due to the size and weight of the spleen, but surgical removal is likely to be of little value except as a symptomatic measure, even considerable splenomegaly appears capable of spontaneous regression.

Spontaneous rupture of the spleen has been reported on one occasion.<sup>103</sup> In this unusual case many lesions were noted in the intima of large sinuses and veins, some of which were thrombosed.

**Liver** The liver appears to be involved only slightly less often than the spleen.<sup>4 64 80</sup> A number of authors report a predilection for the portal areas,<sup>41 80 94 104 105</sup> but this is by no means invariable.<sup>26 100</sup> The organ may be considerably enlarged, but all such enlargements are not necessarily the result of specific involvement — particularly if failure of the right side of the heart is present. Diagnosis has been made by punch biopsy on a number of occasions.<sup>105-108</sup>

In spite of the frequency of involvement, liver function rarely seems to be significantly disturbed. Retention of bilirubin in a bilirubin tolerance test<sup>42</sup> and bromsulphalein retention up to about 30 per cent<sup>29</sup> have been noted. Jaundice has also been reported,<sup>9 109</sup> but a concomitant infectious hepatitis cannot be ruled out in these cases, punch biopsy should prove a useful method of clarifying this point.

**Lung** Involvement of the pulmonary parenchyma is often a prominent feature of the disease. The strong tendency of pulmonary infiltration to regress makes exact evaluation of incidence difficult, but it is likely that if cases are followed for a sufficient period, such involvement will be roentgenographically demonstrable in the large majority. In one series<sup>35</sup> development of such infiltrations was ob-

quency and represent about two thirds of the inclusions, in the spleen they have been seen in all 4 cases in which splenectomy was performed. On the other hand, the laminated inclusions have been seen only twice in cases of generalized sarcoidosis though they have been noted on several occasions in strictly localized sarcoid lesions.

Of the development of the sarcoid lesion relatively little is known with certainty. On several occasions early skin lesions have been examined with varied conclusions. According to Kissmeyer,<sup>8</sup> the initial process is a perivascular inflammatory reaction consisting at first of lymphocytes, later a few epithelioid cells and fibroblasts and, finally, the typical epithelioid cell granuloma. According to Pautrier,<sup>10</sup> the cellular elements are those of the adult lesion from the very start, the epithelioid cells arise by transformation of the local histiocytes and occasionally lymphocytes in the perivascular regions, extending from there into the surrounding tissues. It is possible that, as in many disagreements, there is an element of truth on both sides. Transformation of mononuclear phagocytes into epithelioid cells has been demonstrated both in vivo and in vitro under the influence of tubercle bacilli and their lipid fractions,<sup>77-78</sup> as well as such nonspecific phospholipids as lecithin.<sup>77</sup> Both the fixed reticuloendothelial elements and the wandering tissue macrophages are of this group and presumably capable of such transformation.<sup>79</sup> The various localizations might be expected to occur, therefore, wherever reticuloendothelial elements pre-exist, or wherever a group of wandering tissue macrophages happens to accumulate for any reason—including, possibly, even an unrelated chronic inflammatory process. This might account for the cases in which sarcoid lesions have no apparent relation to the blood vessels,<sup>80</sup> and even for occasional localizations of such lesions at the sites of old scars.<sup>2-81</sup> Apparent transformation of a diffuse and essentially nonspecific infiltration into characteristic lesions has been noted in 1 case.<sup>66</sup> A more certain knowledge of the early lesion would go far toward clarifying some of the many puzzling features of this disease.

The ultimate fate of the sarcoid lesion is not much more definitely known. The lesion may persist in its characteristic form and practically unchanged for indefinite periods, sometimes for years, or it may resorb in a few months. Lesions may be evolving in one area and resolving in others even within the same organ.<sup>85</sup> Although there is little definite evidence to prove it, it seems quite likely that such lesions may resolve completely in many cases, as the experimental tubercle does,<sup>79</sup> leaving little or no trace. On the other hand, a slow process of sclerosis may gradually transform the granuloma into a relatively acellular fibrous nodule or an apparently fused fibrous mass, as has often been noted in microscopical sections. Such extensive fibrosis may produce severe changes in the lung, or scars may follow skin

involvement. Collagen appears to condense about the periphery of the granuloma and extend inward along the reticulum fibers. The epithelioid cells elongate and come to resemble fibroblasts, at the same time diminishing in number. Focal masses of coarse collagen fibers, often seen in lymph nodes in association with these sclerosing nodules, seem to be one possible end-stage of the process, and in 1 autopsied case apparently represented the sole residual evidence of the disease.<sup>82</sup> Such foci are a common finding in routinely examined lymph nodes, however, and may represent a nonspecific termination of more than one pathologic process, or possibly an allergic phenomenon as suggested by Teilum.<sup>83</sup>

### *Clinical and Clinicopathological Features*

The lesions of sarcoidosis have been found in practically every organ in the body at one time or another, and the many regional manifestations so produced have resulted in an exceedingly polymorphic clinical picture. The usually benign character of the disease, as well as its prolonged, erratic and generally unpredictable course, has resulted in a relatively slow accumulation of the data, both anatomic and clinical, necessary to a clear understanding of the clinicopathological findings. It has also been difficult to make an accurate evaluation of the frequency with which the various localizations occur. Cases have been seen by dermatologists, ophthalmologists, roentgenologists and many other specialists, with the result that marked case selection is evident in the published reports, and there has also been a marked slanting in favor of the readily visible localizations. With the increasing number of autopsied cases, however, together with prolonged clinical follow-up study on others, it has become apparent that localizations such as those in the skin and eye actually occur in the minority of cases, whereas localizations in lymph nodes occur in almost all of them.

Pinner,<sup>4</sup> in 1938, and Rubin and Pinner,<sup>69</sup> in 1944, collected 44 autopsied cases from the literature, including their own. More than 70 such cases have now been reported,<sup>24-27, 38-40, 41, 43, 47, 53-90</sup> including those of the uveoparotid syndrome,<sup>91-94</sup> but many of these are incompletely described or are so complicated by caseating tuberculosis that they are difficult to interpret. In several others the diagnosis is open to considerable doubt, and in still others there has been inadequate clinical study before autopsy. From some of these cases, however, it has been possible to construct a composite picture that is in most respects consistent. The autopsy data have also been augmented by an increasing volume of biopsied material from skin, lymph nodes, spleen, liver, bone marrow and other areas.

One of the most characteristic features of the disease is the occurrence of rather extensive dissemination in the absence of significant symptoms. Patients with fairly extensive skin lesions may feel

thrombosis Emphysema, evidences of bronchiectasis and hypertrophy of the right ventricle were noted in a large proportion of the cases

**Heart** Involvement of the heart has been manifested by various clinically demonstrable irregularities such as rhythm disturbances, transient or permanent heart block, cardiac enlargement, congestive failure and electrocardiographic abnormalities, as well as being found at autopsy. Such involvement may be secondary to overburdening of the right side of the heart in cases of pulmonary fibrosis or to direct involvement of the heart by sarcoid lesions. Leitner<sup>110</sup> reports electrocardiographic evidence of myocardial lesions in 8 of 17 cases, intensified by physical work in 7 of 8 cases and abolished by oxygen inhalation in 2.

There is evidence that varying degrees of cor pulmonale probably occur in the majority of cases with extensive pulmonary fibrosis, either with or without demonstrable endarteritis. On the other hand, direct involvement of some part of the heart by sarcoid lesions has been demonstrated in only about 20 per cent of recorded autopsies, and there is little convincing evidence that disturbance of cardiac function can be specifically attributed to such localization in more than a few of them. In several cases such localizations occurred without clinical signs,<sup>92, 123</sup> or in association with marked cor pulmonale sufficient to explain the clinical findings.<sup>93, 123</sup> In another case<sup>87</sup> the history and lesions described strongly suggested a complicating periarthritis nodosa, and in still another, syphilis could not be entirely excluded as a cause of a large scar in the interventricular septum associated with a long history of auriculoventricular dissociation.<sup>123</sup> When the myocardium is massively infiltrated, however,<sup>91, 92, 104</sup> or when the coronary branches may have been involved,<sup>94</sup> cardiac alterations can be reasonably attributed to the specific lesions alone, and it may be of significance that most of the cases with the uveoparotid syndrome that have come to autopsy have shown such involvement. Occasionally, clinical evidence of failure has been difficult to explain except on the basis of such infiltrations, and even when failure is severe, marked improvement may take place.<sup>123</sup> Presumably, too, fortuitous localization in or near the bundle of His would produce derangements such as the transient block observed clinically in some cases.<sup>123, 124</sup> Unfortunately, the many more common causes of cardiac disturbance cannot often be satisfactorily eliminated.

**Kidney** Renal involvement has also been noted in about 20 per cent of the autopsied cases usually in the form of a few scattered lesions. However, in a significant proportion of cases the active phases of the disease have been associated with albuminuria, and in a few there has also been an azotemia, a low or fixed urinary specific gravity, reduced phenolsulfonphthalein excretion and casts.<sup>29, 96, 125-127</sup>

The blood pressure in these cases has usually, but not invariably, been within normal limits. Retinopathy has been described but this also occurs without renal involvement and probably represents an independent lesion.<sup>127</sup> Of particular interest is the fact that in several cases the renal findings and azotemia have cleared up concomitantly with the disappearance of other evidences of systemic sarcoidosis, and in some cases coincidentally with a fall in blood calcium.<sup>29, 127</sup>

Klinefelter and Salley<sup>127</sup> attributed these findings to the mechanical effect of invasion of the renal parenchyma by sarcoid lesions, but the anatomic evidence so far fails to bear this out satisfactorily. Massive invasion of the kidney is rare, but in at least 1 case there were no renal symptoms.<sup>93</sup> Several cases,<sup>127, 128</sup> including 2 seen at this hospital, have been associated with considerable hypercalcemia and hypercalciuria, and under such circumstances it is possible that calcium casts in the renal tubules cause renal shutdown as has been demonstrated in cases of hyperparathyroidism.<sup>129</sup> Such casts have been seen in at least 1 autopsied case<sup>125</sup> but no blood calcium level was recorded. Renal stones, either with or without renal insufficiency, have also been reported.<sup>29, 100, 130</sup>

served in 10 of 12 cases failing to show involvement on initial examination

The lack of correlation between the degree of demonstrable pulmonary infiltration and the respiratory symptoms exhibited by the patient has been repeatedly stressed. It is not uncommon to find extensive involvement in the complete absence of such symptoms, or at most mild cough or dyspnea. Physical signs also tend to be slight or absent unless frank pulmonary tuberculosis is present as well, but spirometric studies may reveal some impairment of pulmonary function.<sup>110</sup> Severe and progressive dyspnea is occasionally seen, usually in association with progressive fibrosing lesions or cardiac insufficiency.<sup>38</sup>

The roentgenographic pattern is by no means pathognomonic and may be mimicked by a wide variety of conditions. It has been described on many occasions<sup>5, 24, 30, 38, 44, 45, 47, 81, 82, 111-115</sup> and consists essentially of two main types, which may coexist: an appearance of disseminated miliary or more coarsely nodular foci, which must be distinguished from hematogenous tuberculosis, and a reticulated appearance associated with linear or strand-like areas extending outward from the hilus along the broncho-vascular ramifications, and resembling lymphangitic carcinomatosis or silicosis. More rarely, areas of coalescent density, suggesting fibrotic induration, or areas of confluent massive density, suggesting pneumonic infiltration, are seen.<sup>38, 43</sup> The infiltrations tend to be diffuse and bilateral, but may be localized in certain phases.<sup>38</sup> Associated hilar adenopathy is usually seen but may be absent.

The roentgenographic appearance of the chest is largely dependent upon the phase of evolution of the disease at any given time, and a number of authors have had the opportunity to follow the phases of development and regression of such lesions with serial roentgenograms.<sup>5, 38, 43, 81, 114</sup> In many cases hilar adenopathy has been the first manifestation, and pulmonary infiltration has appeared to extend fanwise into the parenchyma bilaterally.<sup>81</sup> Early lesions tend to be of the miliary or nodular disseminated type.<sup>5, 38, 43, 112</sup> they are in large measure reversible and may resorb, leaving little or no trace. The linear, strand-like type may also resorb partially or completely, but shows a greater tendency to fibrosis.<sup>38</sup> With the development of the parenchymal dissemination, the hilar lymph nodes may regress,<sup>111</sup> or different rates of development and regression may result in patchy distributions. Localized involvements show some predilection for the parahilar regions or midzones of the lung.<sup>38</sup> Occasionally the basal portions alone are involved,<sup>38, 115</sup> but such localization is not a characteristic feature as was once thought.<sup>47</sup> With regression of the pulmonary lesions, the hilar lymph nodes have sometimes been observed to re-enlarge.<sup>43, 111</sup>

It is probable that the pulmonary lesions resorb more or less completely in the majority of cases,

though regression may be slow. With the onset of interstitial fibrosis, however, complete resorption is no longer possible. This change may be heralded by a delicate striation of the lung fields associated with the areas of miliary density,<sup>5</sup> and eventually there is transformation with conglomerate involvement of varying extent usually associated with nodular or stringy fibrosis. This occurred in about a third of the cases under Reisner's observation,<sup>21</sup> though King<sup>30</sup> failed to observe it at all. Such transformation may be patchy or localized, so that areas of density persist while other lesions regress. The fibrosis may also be associated with areas of emphysema, bronchiectasis or extensive contraction of the lung field. Occasionally, cavitation has been described in the absence of pulmonary tuberculosis,<sup>30, 82, 88, 90, 116</sup> but in the cases that have come to autopsy, the findings seem consistent with a cystic bronchiectasis, others have been interpreted as bullous emphysema.<sup>117</sup> A few cases of spontaneous pneumothorax have also been reported,<sup>118, 119</sup> but whether there is any causal relation is difficult to say. The changes of active pulmonary tuberculosis supervene in about 10 per cent of all cases reported,<sup>41</sup> though the incidence is a little higher in some series.<sup>38</sup> The incidence of tuberculosis among the autopsied cases is, for obvious reasons, considerably greater.<sup>21, 120</sup>

Correlation of all these changes with the underlying pathological findings has been much limited by the relatively small number of detailed autopsy reports available. Sarcoid lesions are scattered throughout the interstitial tissue of the lung in a fashion suggesting a hematogenous seeding of the causative agent, but showing some predilection for regions about blood vessels and bronchi, the interlobular lymphatics and the subpleural areas. In view of the large amounts of lymphoid tissue in these areas,<sup>97</sup> such localization is not surprising and, when prominent, probably accounts for the strand-like linear roentgenographic pattern. It is possible, too, that varying degrees of lymphatic obstruction produced by such localizations account for the increased tendency of such linear infiltrations to fibrose.<sup>38</sup>

Mallory<sup>37</sup> describes 6 cases in which extensive pulmonary fibrosis was associated with miliary granulomatous lesions believed to be entirely consistent with sarcoidosis, and identical with many cases so described in the literature.<sup>86, 89, 116, 121, 122</sup> In these cases, the oldest lesions, consisting almost entirely of acellular whorled collagen, were present beneath the pleura, and about the blood vessels and bronchi near the hilus. More recent granulomas extended into the alveolar septums, which showed gross thickening and distortion. Contiguous lesions showed a marked tendency to fuse, with eventual loss of all traces of lung architecture in these foci. Bronchial walls and less frequently blood vessels were also invaded, the latter showing evidence of

NEW HAMPSHIRE MEDICAL SOCIETY

PROCEEDINGS OF THE ONE-HUNDRED AND FIFTY-SEVENTH ANNIVERSARY

House of Delegates, June 1, 2 and 3, 1948

The report of the Committee on National Emergency Medical Service was then presented

At the spring meeting of the American Medical Association Council on National Emergency Medical Service, held at Chicago April 5 and 6, the New Hampshire Medical Society was represented by the chairman of the Committee. At that session various speakers from different branches of the government and various civilian organization officials were heard and outlined the kind of national emergency that might exist in case of another war. The meaning of atomic warfare was expounded and certain proposals were made for the purpose of arriving at a means of coping with the emergencies that might be created.

It was agreed by most speakers at this session that any future war would be aimed at ruining all the enemy's war-making potential. This would mean the total destruction of his means of communications and his civilian population engaged in operating these national assets. As a corollary it might be inferred that armies in the field and navies in the oceans might be by-passed by the enemy in his effort to strike at the civilian populations, which are the life blood and source of supplies of these armies and navies. This could be accomplished by waging war with atomic bombs and other weapons similarly horrible in their destructive effect and usually termed "special weapons". Under the classification of special weapons would be those having to do with chemical, biologic and bacteriologic warfare. The scope of the destruction caused by the atomic bomb at Nagasaki and Hiroshima is slowly being realized with the information that has accrued as a result of the study that was undertaken since the time of their explosions.

There is reason to believe, from the study of vegetable matter that the effect of the destructive action of atomic energy may be felt through the second and third generations. Whether or not this is applicable to human beings is

still open to question, and studies are being carried out in this direction. All females who were in the atomic area who have become pregnant are being registered, and their progeny will be studied.

It has been stated that we now have atomic bombs that are one hundred to one thousand times more powerful than those exploded at Nagasaki and Hiroshima. The implications of this are almost beyond imagination. It has been estimated by various persons that the Russians, who are now our main potential enemy, will have an atomic bomb by 1951-1955. Recent statements from an official in the air force also imply that the Russians now have or will shortly have an atomic bomb.

It is certainly reasonable to believe that the secret of atomic power cannot remain forever within the grasp of citizens of the United States. It therefore behooves us to devise ways and means of protection against an enemy who might employ atomic energy in his attack upon us. These ways and means may be very different from those conceived in our plans for civilian defense during World War II.

In Great Britain early in World War II and in this country the plan against incendiary bombs was to have fire-fighting units at strategic points in metropolitan and urban centers, and it was intended that these should go out and extinguish any fires that were started. Later in the war, in the face of overwhelming bombing, the method was changed. It then became apparent that the best means was to retire from the area of conflagration and try to protect the periphery. Now in the event of an atomic bomb attack, all our defensive resources would have to be concentrated on the periphery because nothing in the center of the bomb area would be of any use or value. In the central area there would be a great concentration of radioactive material.

This concentration of protection and protective material held on the periphery may have to be quite large in scope and in volume.

the Manhattan project, and of the 40,000 employees on the Bikini Atoll project, not one was injured by radiation. This was due to the infinite care and the skill of the application of the safety factors that were devised and employed.

In this connection it may be pointed out that protection from the secondary radiation following atomic bombing is of tremendous scope. It involves the use by thousands of people of delicate machines and precision instruments. The number of Geiger counters that must be employed in an experiment like the Bikini Atoll experiment is tremendous. When one considers that such instruments must be made in large quantities not only for the urban centers but also for the suburban and rural areas, and when one considers that trained personnel must be ready to use them, it becomes obvious that in this minor division of defense the problem is immense.

It is consideration of these factors that leads one to the conclusion that planning must be on a national level. Cost might now transcend our imagination. Admiral Wilcutts pointed out that it cost Caesar and his Roman Legions 50 cents per enemy killed, that it cost Napoleon \$3000 per enemy killed. The Civil War cost the Union \$5000 for every Confederate killed, World War I cost this country \$20,000 for every enemy killed, and World War II cost this country \$200,000 for every German and Japanese killed. He estimated that World War III would cost this country \$1,000,000 for every enemy killed.

It must be evident from the brief foregoing comments that plans for such disaster and such national emergency must necessarily be on a national level. It must also be equally evident that planning, training and knowledge concerning this problem must be in everyone's mind. At the session of the Council on National Emergency Medical Service, specific recommendations were few because it was believed that if a great deal of work were done at a state level and much expense was involved in formulating and organizing and putting into effect a program on a state level, thereafter the program that would be formulated by the Office of Civilian Defense might be out of harmony with such state-level programs and that the whole thing would have to be done over. However, it was agreed that certain specific things might be done by the state medical societies while they were awaiting a policy and program from a higher level. Specifically, it was recommended that the societies appoint or elect a subsidiary national emergency medical committee, and that the various subdivisions of the state medical societies elect or appoint corresponding committees for national-emergency medical service. A resolution to this effect was adopted by the Council on National Emergency Medical Service. Our society has such a committee, but the county societies do not as yet.

It was especially recommended that all physicians inform themselves regarding atomic energy, the implications of its use in atomic warfare and measures that might be employed in defense against it.

It then follows that defense against the type of warfare outlined in the preceding paragraphs must have two components: military and civilian.

The perfection of the military component is not of detailed interest to us except as it affects us as physicians. The military must make known its needs and its probable methods of meeting these needs. The new Selective Service law, which is reported out of committee and which will probably be passed by Congress, gives the power to the President to call into service any physician, dentist or veterinarian up to the age of forty-five. The committee asks the House of Delegates to instruct its delegate to the American Medical Association to reaffirm and re-emphasize the principles endorsed in June, 1947, by the American Medical Association House of Delegates after its deliberations on the use of medical personnel by the military services during World War II.

Representatives of the Surgeon General of the Air Force and of the Surgeon General of the Army, present at the spring meeting of the Council on National Emergency Medical Service stated that their services were re-examining their physician needs and were attempting to draw plans that would more effectively utilize their medical personnel. They said that both services were in the process of making studies to see how the work load of the medical personnel might be lightened in administrative duties. They were also attempting to make plans for mobilization where-

by the physical facilities, plants and equipment for hospitals and other medical units might be activated by nonmedical personnel, thereby enabling them to leave the practicing physician where he is until these plants and equipment and facilities were actually ready for his services with patients to treat.

It is agreed that if the military establishment is enlarged by Selective Service or a universal-military-training program, a large number of physicians will have to be obtained for military service. The Council resolved to petition the Board of Trustees of the American Medical Association to seek regulation or legislation whereby selection of physicians for a new army or a universal-military-training program would operate as follows: graduates of V-12 or ASTP programs who had not repaid the Government for their education by serving a just length of time in the military service would be selected first. The next group for selection for service within the age groups mentioned should be physicians, otherwise qualified, who did not serve in World War II.

In the event of the passage of a selective service act or a universal-military-training program that would register the youths reaching ages eighteen or nineteen, it has been estimated that 1,200,000 men will reach the age of eighteen years every year until 1951, when that number drops off until 1958 by reason of a decline in the birth rate from 1933 to 1941. Of this number reaching the age of liability, so far as the Selective Service program goes, a large number would have to be examined. The Council on National Emergency Medical Service, recalling many mistakes of World War II, adopted a resolution asking that the examination machinery be set up so that these candidates would undergo one examination instead of several physical examinations as in World War II. This matter of examining a single candidate many times accounted for many physician man hours wasted in World War II.

Colonel Eanes, of the Office of Selective Service Records, stated that the Government would probably ask the physicians of this country to perform these examinations on a voluntary, free-of-charge basis. He stated that the reasons for asking for this were that the full value of physicians' services cannot be compensated, that any such payments would increase the public tax burden, and that the making of any payments would encourage cultist and other quasi-medical practitioners to seek inclusion as examiners.

This matter was discussed by the Council on National Emergency Medical Service, and it was believed that the reasons advanced for not paying physicians for their services were not reasonable, but that this matter should be decided by the medical profession through the delegates to the American Medical Association. The committee believes that physicians, as well as all others supplying services and material to the Government, should be paid in the amount that is just and proper for their services. It is certainly true that in World War II the division of work in the examination of candidates was often not equitable, with some ultra-conscientious physicians shouldering the greater part of the burden in many cases.

The Council also decided to recommend to the armed forces that they study plans whereby men might be rotated between foreign duty and duty within the continental United States. Also, they thought that some study might be given to the matter of rotating physicians between military and civilian duty in case of a prolonged conflict.

At the spring meeting of the Council on National Emergency Medical Service it was stated that the ratio of physicians to civilian population at the present time is 1:740. During World War II the ratio of doctors remaining in civilian practice to the population reached the low figure of 1:1450. This was a general cross-section figure. In some states, notably Tennessee and Missouri, the ratio dropped lower. In other states, notably New York, the ratio remained higher, and in metropolitan New York City district the ratio never dropped below 1:1000. A resolution was passed by the Council on National Emergency Medical Service that in the event of another national emergency the ratio of physicians to civilian population should be maintained at or above 1:1250.

In connection with the equitable distribution of physicians between the civilian population and the armed forces, it was pointed out that in the table of organization of the new national defense act, the Director of Civilian Defense

Immediately upon hearing of the disaster at Nagasaki, the Japanese medical officer of the district started toward Nagasaki with a whole trainload of medical supplies. He never got nearer than within 60 miles of Nagasaki before his whole trainload of medical supplies was used up by the outbound refugees streaming forth from the bomb area. The bomb victims remaining within the area never received medical treatment.

One must contemplate with some dismay a type of warfare that claims the lives of and maims not only civilians but also their doctors and nurses and their hospital personnel, to whom they constantly turn for relief in time of physical pain and disaster. At Nagasaki there was a medical school with 800 nurses and doctors. About 200 were on vacation at the time of the explosion. Of the remaining 600 there was not one survivor. At Hiroshima, out of 300 physicians, 260 were killed or injured, and 75 per cent of the nurses and technicians were killed or injured. All the hospitals were destroyed, and there was no light or power.

We must consider the problem of national defense against a type of warfare of this kind in terms of supplies and personnel, which heretofore we have never had to consider. It is estimated, for example, that if a bomb the size of the one that was dropped on Nagasaki were dropped on the City of Boston, we should need in the next thirty-six hours 200,000 units of blood or plasma. The need for this quantity of blood and plasma, as well as for the numbers of skilled personnel for the collection, processing and administration of all this blood, not to mention the numbers of donors required, almost staggers the imagination. If we can consider at the same time that such a disaster would have completely inactivated the Massachusetts General Hospital, the Peter Bent Brigham Hospital, the Boston City Hospital, the Children's Hospital and the Beth Israel Hospital, in addition to all their doctors and all their nurses, we can have a rough concept of the scope and magnitude of the problem of recovery and rehabilitation from such a blow. Let us again emphasize at this point that we now have atomic bombs one thousand times as powerful as those dropped on Nagasaki and Hiroshima.

The information gained by the explosions of the atomic bombs at Nagasaki, Hiroshima and the Bikini Atoll project teaches us that there are two effective ways to cause destruction: to explode the bomb in the water and to explode it just above roof-top level.

Almost all cities are weak at their roof tops, and the destruction caused by roof-top explosion is almost incalculable. In addition to the blast effect and the radiation effect, there is a tremendous effect from flying debris capable of inflicting severe damage.

In addition to the immediate local blast effect of exploding an atomic bomb in the water, it was pointed out not only that the water itself was seriously contaminated but also that the mist and spray that would shoot almost to the stratosphere loaded with radiation material was equal to several hundred tons of radium.

The gamma radiation from a bomb exploded at roof-top level equals that of several thousand tons of radium. In the water explosion it was estimated that there was radiation equal to from 1 to 100 tons of radium in the mist, which could be carried by prevailing winds over long distances and precipitate out at many points along its travels.

Dr. Stafford Warren drew an impressive analogy from an incident that occurred during his air travel from Los Angeles to Chicago. He stated that near Denver there was a sandstorm in progress. One hundred and fifty miles further east there was a bank of cumulus clouds. Their tops were yellow with the particles of sand that had been picked up in Denver. The bottoms of the clouds were pure white. This sand picked up in the storm in Denver was thus being carried a considerable distance. He then stated that it was a well known meteorologic fact that cumulus clouds 100 miles square in area could precipitate out in an area one mile square. He then pointed out that vegetable matter is capable of concentrating radio activity and mineral matter in the soil up to 100 or 1000 times during the process of growth. The inference is that if atomic radiant energy particles should be diluted in mist or cloud banks, they might, by precipitation, be concentrated in a small area. Even if they were precipitated out of clouds over a given area in dilute concentration, the vegetable matter in that

given area would or could concentrate them to a toxic or lethal degree.

The contamination of water that results from an explosion could create serious damage to a relatively large area. If a bomb exploded in Lake Michigan it might contaminate the whole St. Lawrence waterway, and the contamination might be carried down to the mouth of the St. Lawrence to ruin all the fishing banks off the coast, thus imperiling a large source of the nation's fish-food supply.

#### *Analysis of the Destructive Effect of the Atomic Bomb*

The difference between ordinary high explosives such as those used in World War II and atomic bombs is the almost inconceivable magnitude of the explosive force of the second over the first and, secondarily, the liberation of radiant energy by the atomic bomb covering the whole mass of wave lengths from heat waves to million-volt gamma waves.

The effects on people of atomic-bomb explosions may relatively be divided into three main groups: actual physical injury caused by destructive violence of flying debris and particles through the air (this results in contusions, lacerations and fractures with which every physician is familiar and which he is equipped to treat in both military and civilian life), the second effect is that due to blast (and here most physicians, especially veterans of World War II, are on familiar ground), including internal, concealed hemorrhage in vital organs, petechiae of the brain and small areas of bleeding in many parts of the vascular bed, often in solid organs and in the gastrointestinal tract, the third and important injuries are those due to radiant energy. Of the radiant energy resulting from an atomic-bomb explosion, the most important is the gamma radiation energy. This radiation is actually the same as x-radiation. In an atomic bomb area these are of 200,000,000-volts electromagnetic force. They are lethal to anyone within a mile and dangerous to anyone within a mile and a half, but their effective range is apparently limited to two miles. The injurious effect is produced immediately, since the rays move with the speed of light, and they are produced at the instant of explosion. There is little one can do about protection against these rays if he is within a two-mile area of the explosion.

It was estimated by Dr. Shields Warren that a person might be protected if he were a mile and a half away from the blast, and if he had already erected and stood behind a protected screen made up of a 12-foot-thick, steel, reinforced concrete wall, with a second layer composed of a wall of heavy oil 4 feet thick and a third layer composed of an 8-foot-thick wall of lead, but there was no positive assurance that he would be protected.

About a mile from the bomb explosion at Nagasaki there was an officers' club solidly constructed of bomb-proof material, which was not injured by the blast of the atomic bomb. There was no flying debris and no destruction to the building at the time the bomb went off. Inside were about 60 officers and men. None were apparently injured. But three months after the date of the bomb explosion there was not one survivor. All died from secondary effects of radiant energy.

The atomic bomb would immediately create many deaths. A single bomb on each of twenty key cities would result in millions of deaths. Large-scale work would be necessary to repair the immediate physical injury to human beings resulting from the flying debris and the blast. Secondary measures that would be tremendous in scope would be necessary for the treatment of victims of radiation. This would involve the co-operation of all. It would involve large scale checking of white-cell counts and differential blood counts on radiation victims, as well as accurate record-taking and record-keeping on such victims.

The streams of gamma rays penetrate immediately but the effects are noted later. This physical quality is already useful to us as physicians. We treat radiosensitive cancer cells with radiant energy to destroy them, but we are familiar with the later appearance of the destructive effect of the radiation on normal cells, as well as the toxic effect on the patient as a whole in case of overdosage.

The treatment of victims of radiation will involve large scale use of blood transfusions and penicillin to prevent secondary infection in victims until such time as their own hematopoietic systems can resume their normal function.

In all fairness, after putting forth this dire picture, it should be stated that of the 200,000 employees engaged on

formed the Grange, the Farm Bureau, the State Department of Health and other groups in the State that it exists and is anxious to co-operate in any matters falling within its sphere.

The chief conclusion to be drawn from the National Rural Health Conference is that there are many groups throughout the country actively pushing their favorite health programs, and that these people mean to get results through Government action if necessary or through voluntary plans of various kinds if these can be set in motion and made to work. The Farmers' Union, for instance, has been actively supporting the Wagner-Murray-Dingell Bill, whereas those in public-health work are seeking to extend the scope and function of public-health units and activities. Some of these things may be good and some bad, but the only way the medical profession can protect itself and the public from programs that are not good is to be conscious of what is going on and to be ready with something better.

Much Government-sponsored health activity is good and deserves our understanding and co-operation. Furthermore, there seems little doubt that the expense of much of the most important health activities especially in the realm of preventive medicine, is such that there is no practical hope of getting things done without financial aid from the federal Government. Hospital-construction and school-lunch programs are but illustrations that could be multiplied many times, quite apart from the many phases of public health that have long been taken for granted as Government responsibility. At the same time, it is very important to avoid duplication of services, and to avoid a situation in which lay personnel will have control of matters that can properly be handled only by physicians.

It is clear that there is an increasing demand for modern medical care, together with an increasingly clear understanding of what this involves, in the field of preventive as well as in curative medicine. If these demands are to be properly met, the medical profession must take an active part in meeting them.

WILLIAM F. PUTNAM, *Chairman*

Dr. Sycamore, for the Committee on Officers' Reports, recommended that the report be accepted, that the Committee be instructed to continue to study and report on the needs and the trends in rural medicine, and that it is desirable that the Committee be represented at the National Conference on Rural Health.

He moved the adoption of this portion of the report.

This motion was duly seconded and was carried.

The report of the Committee on Tuberculosis was then presented.

The year 1947 registered a new all-time low in tuberculosis mortality in New Hampshire. The Division of Vital Statistics of the State Department of Health reports that deaths from all forms of tuberculosis in 1947 dropped to 82, or 8 less than the previous low of 90 in 1945.

The Division of Vital Statistics further states that the 82 deaths include 74 of New Hampshire residents that occurred in the State, and 8 of New Hampshire residents that occurred outside the State—4 residents of Manchester (World War I veterans) who died at the Rutland State Sanatorium, Rutland, Massachusetts; 1 in Florida; 1 in Vermont; 1 at Saranac Lake, New York, and 1 in Massachusetts elsewhere than at Rutland.

The 1947 tuberculosis mortality, based upon deaths of residents occurring inside and outside the State, registers a new all-time low rate of 16 per 100,000 population as compared with the previous all-time low of 18.7 in 1945.

The large reduction in tuberculosis mortality in 1947 is particularly gratifying in view of the fact that the number of deaths increased in New Hampshire in 1946 to a toll of 115 and a rate of 22.5 as contrasted with the all-time low of 90 deaths and a rate of 18.7 in 1945.

Analysis of the statistics by three-year periods for the past thirty years indicates that there has been a persistent

and continuous decline in the tuberculosis mortality in the State. However, the degree of reduction in the mortality has lessened since 1942. It is a well recognized fact that it requires more intensive effort to lower a low death rate from an infectious disease than a high one.

The 1947 tuberculosis statistics for the states of the Union are not available as yet. However, it is confidently anticipated that New Hampshire will be in the sixth or seventh lowest place in the table of tuberculosis mortality.

It is perhaps advisable at this point to quote the old axiom—"Unceasing vigilance is the price of liberty." This is particularly true in the campaign for the eradication of human tuberculosis.

To maintain the gains already won, and to continue to advance toward winning the ultimate eradication of the disease, means ever-increasing extension and intensification of the well demonstrated program of early discovery, prompt treatment, supervision and rehabilitation of patients with tuberculosis.

The remarkable progress achieved in New Hampshire is due in a considerable degree to the wholehearted efforts of the members of the Society. The physicians of New Hampshire are the first line of defense and attack in the fight against the disease. This has been amply demonstrated during the past year in the increasing use of the tuberculin test and chest x-ray examination by the physicians in the examination of thousands of "suspects," "contacts" and even in their routine examinations.

We again urge increasing use of these effective methods for the early detection of tuberculous infection and disease. The New Hampshire Tuberculosis Association is ready to provide chest x-ray films for persons referred by physicians. Furthermore, the New Hampshire State Sanatorium and the New Hampshire Tuberculosis Association continue to offer their services for interpretation of chest x-ray films sent to them.

The records in the chest diagnostic clinics prove that the physicians of the State, if they are determined to do so, can perform a better service of suspecting and discovering active tuberculosis cases year in and year out, than any other agency. It is noteworthy that in the past year as in other years, more cases of active pulmonary tuberculosis were found among patients referred to the chest diagnostic clinics than in any other group of people examined, for the reason that significant symptoms cause patients to consult their physicians with resulting referral to the clinics.

Your committee hopes that some progress may be made in the near future in the routine chest x-ray examination of all patients admitted to hospitals. At present, health departments and hospital budgets do not permit such a procedure. However, a demonstration study may be developed in one of the smaller hospitals.

Bed rest and collapse therapy continue to be the most effective elements of treatment and cure for tuberculosis patients.

Despite considerable research activity, the full value of streptomycin in the treatment of tuberculosis is not yet known and the indiscriminate use of the drug is not advocated by medical opinion. It is quite possible that the vast increase in research brought about by streptomycin may result in the discovery of an antibiotic of more definite value.

During the past year interest has increased among public-health officials and the members of the medical profession, with reference to the possible use of BCG as a preventive in tuberculosis. In a recent statement of policy adopted by the Executive Committee of the American Trudeau Society, the following conclusions are announced:

Vaccination with BCG does not provide complete protection against tuberculosis and until further controlled studies are conducted, cannot be recommended for the general population. However, since BCG appears to provide some degree of protection, it is recommended for members of groups constantly exposed to tuberculosis, if they have a negative reaction to the tuberculin test.

BCG is recommended for the following groups if they are subjected to more than ordinary exposure to tuberculosis: doctors, medical students and nurses, hospital and laboratory personnel whose work brings them constantly in contact with the tubercle bacillus, persons who are unavoidably exposed to tuberculosis in the home and patients and em-

is under the aegis of the Secretary of the Army, the Secretary of the Navy and the Secretary of the Air Force. He would probably make recommendations regarding the allocation of civilian physicians after consulting with his superiors. It was pointed out that the physicians of the United States as a whole were represented at a relatively low echelon. It was strongly urged by the Council on National Emergency Medical Service that the physicians of the United States have representation on the National Security Resources Board, which is directly responsible to the President.

As stated above, plans and enabling legislation for civilian defense must necessarily be on a national level. It was pointed out at the meeting of the Council on National Emergency Medical Service that two things might be done now while we are awaiting directives or a plan from the Office of the Director of Civilian Defense: physicians should be trained and educated in the knowledge and implications of atomic warfare—they should then ready themselves to take an active part in imparting this knowledge to the civilian population, and a complete inventory should be made of the medical resources within the state. This might well entail an integration of the Governor's plan for coping with civil disaster.

The committee has the following recommendations to make to the House of Delegates: that the machinery for procurement and assignment of physicians within the medical society be reviewed (it is recommended that a procurement and assignment board be set up rather than have the responsibility for procurement fall upon one person), that the physicians of this Society be informed regarding atomic energy, its destructive effects and the measures that might be employed to protect people against these destructive effects, and that they be kept currently cognizant of new developments in protective devices and methods as these become known, that component county-medical-society groups within the New Hampshire Medical Society be asked to appoint or elect county committees on National Emergency Medical Service to work with the State committee of the same name, that the House of Delegates instruct its delegate to the American Medical Association to move that in the event of the passage of a selective service act or a universal-military-training program, a single physical examination for candidates, which is acceptable to the armed forces, be made operative, that the House of Delegates instruct the delegate to the American Medical Association to move that physicians engaged in these examinations should be paid for their work, and that the House of Delegates instruct the delegate to the American Medical Association to vote affirmatively in a proposal in the American Medical Association House of Delegates to attempt to obtain American Medical Association representation on the National Security Resources Board.

DANIEL J. SULLIVAN, *Chairman*  
JOSEPH M. MCCARTHY  
CLARENCE E. DUNBAR  
BERNARD J. MANNING  
JOHN C. ECKELS

Dr. Sycamore, for the Committee on Officers' Reports, moved that the House of Delegates express its commendation of the Committee for its comprehensive and illuminating report.

This motion was duly seconded and was carried.

He then recommended that the resolutions of the Committee on National Emergency Medical Service be adopted.

This motion was duly seconded and was carried.

The Committee on Officers' Reports then recommended that the Committee on Emergency Medical Service be instructed to consider and make recommendations to the officers of the Society regarding appropriate means of educating the physicians of New Hampshire concerning the medical implications of atomic energy.

This motion was duly seconded and was carried.

The report of the Committee on Rural Health was then read, as follows:

This consists of a report on the activities of this committee, and a report on the National Conference on Rural Health held in Chicago, February 6 and 7, 1948.

The reasons for the existence of this new committee may not be altogether apparent, depending largely on whether one considers that rural health problems exist in this state. Fortunately they do not exist to the extent that is true in some parts of the country, where there are large groups of people seriously underprivileged because of belonging to a racial minority group, or for other reasons. In general it is true that in New Hampshire most of the people can get at least fairly satisfactory medical care; on the other hand, many of our people are existing at a level of health below that which is commensurate with present medical knowledge, and many will believe that a real problem exists so long as that is true.

The question what the Society is called upon to do about it depends largely on how important we consider it for the medical profession to have something to do with health plans and programs that may be put into effect. For as was made abundantly clear at the national conference, many groups fostering schemes and programs of various kinds may in the future have an influence not only on the health of the country but also on the conditions of medical practice.

Your committee has had one formal meeting, some informal conversations and a considerable amount of correspondence. The chairman attended the National Conference on Rural Health representing the Society. Not to go too far afield, the Committee confined its attention largely to the following matters: the supply of physicians (and other medical personnel) in rural areas, the number and adequacy of hospitals, the question of so-called state medicine as it might affect rural medicine in New Hampshire, and organizations and groups interested in these matters and their programs.

In the absence of a formal survey such as has been carried out by the rural health committees of some of the other states, we have no statistical data to present, so far as the Committee has learned, there are no areas of desperate medical need in the State at the present time, though there are many areas where additional medical personnel and facilities could be used. The Committee is convinced, however, that two types of areas constitute potential danger spots for the future—namely, areas that are remote from good hospitals, and areas that are served exclusively by so-called closed staff hospitals. Well trained young physicians are increasingly unwilling to enter rural general practice in such locations. The rapidly growing extent to which the modern practice of medicine is dependent on hospital facilities, need not be dwelt upon, and although it is still possible to practice scientific medicine in the office and home with relatively little dependence on hospitals, the labor, time and other difficulties involved make it seem almost wholly out of the question to those with present-day medical training.

The Committee endorses the purposes of the Hill Burton Hospital Construction Act, and hopes that the New Hampshire communities in need of new or improved hospital facilities will take full advantage of its provisions.

The Committee also believes that it is in line with the present-day trend to include a section on general practice on hospital staffs, and to admit general practitioners to the hospital staffs as officially recommended by the American Medical Association, to re-evaluate the policies governing the so-called closed-staff hospitals, with a view to eliminating from this State areas in which well trained general practitioners will believe that the practice of medicine is unattractive or impossible. It seems to the Committee that if this situation continues, in the foreseeable future there may be a serious lack of competent general practitioners not only in some of our more remote areas but also in the very shadow of some of our best institutions.

In addition to the points just mentioned, the Committee recommends that its existence be continued, that organized medicine may keep its finger on the pulse of movements and trends in the field of rural health that may be of vital concern to all of us, and that for the same reason, the Society continue to be represented, preferably not by the same individual, at national conferences. The Committee also

formed the Grange, the Farm Bureau, the State Department of Health and other groups in the State that it exists and is anxious to co-operate in any matters falling within its sphere

The chief conclusion to be drawn from the National Rural Health Conference is that there are many groups throughout the country actively pushing their favorite health programs, and that these people mean to get results, through Government action if necessary, or through voluntary plans of various kinds if these can be set in motion and made to work. The Farmers' Union, for instance, has been actively supporting the Wagner-Murray-Dingell Bill, whereas those in public-health work are seeking to extend the scope and function of public-health units and activities. Some of these things may be good and some bad, but the only way the medical profession can protect itself and the public from programs that are not good is to be conscious of what is going on and to be ready with something better.

Much Government-sponsored health activity is good and deserves our understanding and co-operation. Furthermore, there seems little doubt that the expense of much of the most important health activities, especially in the realm of preventive medicine, is such that there is no practical hope of getting things done without financial aid from the federal Government. Hospital-construction and school-lunch programs are but illustrations that could be multiplied many times, quite apart from the many phases of public health that have long been taken for granted as Government responsibility. At the same time, it is very important to avoid duplication of services, and to avoid a situation in which lay personnel will have control of matters that can properly be handled only by physicians.

It is clear that there is an increasing demand for modern medical care, together with an increasingly clear understanding of what this involves, in the field of preventive as well as in curative medicine. If these demands are to be properly met, the medical profession must take an active part in meeting them.

WILLIAM F. PUTNAM, *Chairman*

Dr. Sycamore, for the Committee on Officers' Reports, recommended that the report be accepted, that the Committee be instructed to continue to study and report on the needs and the trends in rural medicine, and that it is desirable that the Committee be represented at the National Conference on Rural Health.

He moved the adoption of this portion of the report.

This motion was duly seconded and was carried.

The report of the Committee on Tuberculosis was then presented.

The year 1947 registered a new all-time low in tuberculosis mortality in New Hampshire. The Division of Vital Statistics of the State Department of Health reports that deaths from all forms of tuberculosis in 1947 dropped to 82, or 8 less than the previous low of 90 in 1945.

The Division of Vital Statistics further states that the 82 deaths include 74 of New Hampshire residents that occurred in the State, and 8 of New Hampshire residents that occurred outside the State—4 residents of Manchester (World War I veterans) who died at the Rutland State Sanatorium, Rutland, Massachusetts, 1 in Florida, 1 in Vermont, 1 at Saranac Lake, New York, and 1 in Massachusetts elsewhere than at Rutland.

The 1947 tuberculosis mortality, based upon deaths of residents occurring inside and outside the State, registers a new all-time low rate of 16 per 100,000 population as compared with the previous all-time low of 18.7 in 1945.

The large reduction in tuberculosis mortality in 1947 is particularly gratifying in view of the fact that the number of deaths increased in New Hampshire in 1946 to a toll of 115 and a rate of 22.5 as contrasted with the all-time low of 90 deaths and a rate of 18.7 in 1945.

The committee has the following recommendations to make to the House of Delegates: that the machinery for procurement and assignment of physicians within the medical society be reviewed (it is recommended that a procurement and assignment board be set up rather than have the responsibility for procurement fall upon one person); that the physicians of this Society be informed regarding atomic energy, its destructive effects and the measures that might be employed to protect people against these destructive effects, and that they be kept currently cognizant of new developments in protective devices and methods as these become known; that component county-medical-society groups within the New Hampshire Medical Society be asked to appoint or elect county committees on National Emergency Medical Service to work with the State committee of the same name; that the House of Delegates instruct its delegate to the American Medical Association to move that in the event of the passage of a selective service act or a universal-military-training program, a single physical examination for candidates, which is acceptable to the armed forces, be made operative; that the House of Delegates instruct the delegate to the American Medical Association to move that physicians engaged in these examinations should be paid for their work; and that the House of Delegates instruct the delegate to the American Medical Association to vote affirmatively in a proposal in the American Medical Association House of Delegates to attempt to obtain American Medical Association representation on the National Security Resources Board.

DANIEL J. SULLIVAN, *Chairman*  
JOSEPH M. MCCARTHY  
CLARENCE E. DUNBAR  
BERNARD J. MANNING  
JOHN C. ECKELS

Dr. Sycamore, for the Committee on Officers' Reports, moved that the House of Delegates express its commendation of the Committee for its comprehensive and illuminating report.

This motion was duly seconded and was carried.

He then recommended that the resolutions of the Committee on National Emergency Medical Service be adopted.

This motion was duly seconded and was carried.

The Committee on Officers' Reports then recommended that the Committee on Emergency Medical Service be instructed to consider and make recommendations to the officers of the Society regarding appropriate means of educating the physicians of New Hampshire concerning the medical implications of atomic energy.

This motion was duly seconded and was carried.

The report of the Committee on Rural Health was then read, as follows:

This consists of a report on the activities of this committee, and a report on the National Conference on Rural Health held in Chicago, February 6 and 7, 1948.

The reasons for the existence of this new committee may not be altogether apparent, depending largely on whether one considers that rural health problems exist in this state. Fortunately they do not exist to the extent that is true in some parts of the country, where there are large groups of people seriously underprivileged because of belonging to a racial minority group, or for other reasons. In general it is true that in New Hampshire most of the people can get at least fairly satisfactory medical care; on the other hand, many of our people are existing at a level of health below that which is commensurate with present medical knowledge, and many will believe that a real problem exists so long as that is true.

The question what the Society is called upon to do about it depends largely on how important we consider it for the medical profession to have something to do with health plans and programs that may be put into effect. For as was made abundantly clear at the national conference, many groups fostering schemes and programs of various kinds may in the future have an influence not only on the health of the country but also on the conditions of medical practice.

Your committee has had one formal meeting, some informal conversations and a considerable amount of correspondence. The chairman attended the National Conference on Rural Health representing the Society. Not to go too far afield, the Committee confined its attention largely to the following matters: the supply of physicians (and other medical personnel) in rural areas, the number and adequacy of hospitals, the question of so-called state medicine as it might affect rural medicine in New Hampshire, and organizations and groups interested in these matters and their programs.

In the absence of a formal survey such as has been carried out by the rural health committees of some of the other states, we have no statistical data to present, so far as the Committee has learned, there are no areas of desperate medical need in the State at the present time, though there are many areas where additional medical personnel and facilities could be used. The Committee is convinced however, that two types of areas constitute potential danger spots for the future—namely, areas that are remote from good hospitals, and areas that are served exclusively by so-called closed staff hospitals. Well trained young physicians are increasingly unwilling to enter rural general practice in such locations. The rapidly growing extent to which the modern practice of medicine is dependent on hospital facilities, need not be dwelt upon, and although it is still possible to practice scientific medicine in the office and home with relatively little dependence on hospitals, the labor, time and other difficulties involved make it seem almost wholly out of the question to those with present-day medical training.

The Committee endorses the purposes of the Hill Burton Hospital Construction Act, and hopes that the New Hampshire communities in need of new or improved hospital facilities will take full advantage of its provisions.

The Committee also believes that it is in line with the present-day trend to include a section on general practice on hospital staffs, and to admit general practitioners to hospital staffs as officially recommended by the American Medical Association, to re-evaluate the policies governing the so-called closed-staff hospitals, with a view to eliminating from this State areas in which well trained general practitioners will believe that the practice of medicine is unattractive or impossible. It seems to the Committee that if this situation continues, in the foreseeable future there may be a serious lack of competent general practitioners not only in some of our more remote areas but also in the very shadow of some of our best institutions.

In addition to the points just mentioned, the Committee recommends that its existence be continued, that organized medicine may keep its finger on the pulse of movements and trends in the field of rural health that may be of vital concern to all of us, and that for the same reason, the Society continue to be represented, preferably not by the same individual, at national conferences. The Committee has

more patients died of accidents of pregnancy than of anything else, with hemorrhage of childbirth coming into second place. It is the hope of the Committee that the maternal death rate will soon reach what might be considered an irreducible minimum.

The Committee further classifies the cases, for purposes of this study, into four groups, as follows:

- Group I Cases in which the patient was at fault because of refusal of prenatal care, neglect, self-induced abortion and so forth (5 cases)
- Group II Those in which the obstetric treatment was inadequate (2 cases)
- Group III Those which were apparently unavoidable (7 cases)
- Group IV Cases in which data were insufficient and, therefore, undetermined (1 case)

After the Committee has made a decision in each case, including suggestions for conduct in the individual case,

TABLE 1 Maternal Deaths by Cause

CAUSE	NO OF DEATHS	
	ASSIGNED BY INTERNATIONAL LIST OF CAUSES OF DEATH	ASSIGNED BY COMMITTEE
Abortion (spontaneous therapeutic, or of unspecified origin) with mention of other infection	1	1
Abortion (induced for nontherapeutic reasons by persons other than mother herself) with mention of infection	1	1
Ectopic gestation without mention of infection	1	1
Hemorrhage of childbirth and puerperium other and unspecified hemorrhages	2	2
Puerperal thrombophlebitis	1	1
Acute yellow atrophy of liver (puerperal)	1	1
Other puerperal toxemias	2	2
Other specified conditions of childbirth	3	1
Other and unspecified conditions of childbirth and puerperium	3	1
Deaths due to anesthesia	—	3
Surgical death (following cesarean section)	—	1
	15	15

a letter is written to the reporting physician containing this information for his use.

Tables 1-3 show the maternal death rates by years since 1935, maternal death rates by counties and the number of maternal deaths by cause for the year 1947.

The Committee cannot do an exhaustive study of infant deaths or stillbirths in this report, but Table 4 demonstrates

TABLE 2 Maternal Death Rates per 1000 Live Births \*

YEAR	RATE
1935	6.5
1936	5.4
1937	6.1
1938	4.8
1939	4.2
1940	5.8
1941	3.1
1942	1.9
1943	1.7
1944	2.9
1945	1.8
1946	1.4
1947	1.1

\*The number of births in 1947 was 13,638.

causes of death of infants under one year of age, and Table 5 the chief causes of death in stillbirths.

This year, as a new phase of the study of maternal deaths the Committee asked all hospitals in the State to report the number of cesarean sections performed during the calendar year 1947. Of 31 hospitals contacted, all but two responded

The total number of cesarean sections performed in New Hampshire in 1947 was 383 (Table 6). This means that of 13,638 live births, the method of delivery in 383 was by cesarean section. In this year's report 5 of the 15 mothers

TABLE 3 Number of Maternal Deaths By County

COUNTY	URBAN	RURAL	TOTAL

who died had had cesarean sections for various indications.

In terms of percentage, this means that of the 15 mothers who died 33.3 per cent had cesarean sections. However, it should be noted that in terms of deaths of all mothers on whom sections were performed, slightly more than 1 mother out of 100, or 1.3 per cent, died. The Committee believes

\*Infant death rate per 1000 live births in 1947 28.1

that the figures speak for themselves and is attaching to the report a tabulation of cesarean sections by counties.

In studying maternal mortality rates by years (Table 2), it is interesting to note that the highest rate recorded oc-

ployees of mental hospitals, prisons and other custodial institutions among whom the incidence of tuberculosis is known to be high

It appears that in New Hampshire, which has a low tuberculosis death rate, experimental methods are out of place while the well demonstrated fundamental procedures in the discovery, diagnosis, prevention and treatment of tuberculosis continue to win results. We must continue and extend these well developed resources, ever hopeful that a specific cure or preventive may be found, and thus hasten the victorious conclusion of humanity's struggle against the tubercle bacillus

ROBERT B. KERR  
FRANK G. SELDON  
JOHN D. SPRING

Dr Sycamore moved that this report be accepted

This motion was duly seconded and was carried

The report of the Committee on Child Health was then read, as follows

In the year 1947 the Committee sent out a letter to the doctors in the State, encouraging them to advocate breast feeding of babies. In co-operation with the New Hampshire State Department of Health, it has revised the baby's feeding card. This card is widely used in the State as a schedule for infant feeding, and is distributed by the Division of Maternal and Child Health.

The New Hampshire Pediatric Society visited the Laconia State School on February 18, 1948. The following motion was passed by this Society:

That the Chairman of the Child Health Committee of the New Hampshire Medical Society report to the House of Delegates at the next annual meeting, expressing appreciation of the work done at the Laconia State School by Dr Depner. Realizing that there are many needs to be met at the State School, particularly with regard to increased personnel, it is requested that the New Hampshire Medical Society express the need for increased appropriations for the Laconia State School.

It is the opinion of the Committee that the main need for improvement in the medical care of our children is for more health supervision and routine checkups. The American Academy of Pediatrics survey will be completed this year, and our future plan of attack will probably coincide with theirs.

THOMAS B. WALKER, *Chairman*

Dr Sycamore for the Committee on Officers' Reports recommended that the following resolution be considered, with reference to the report of the Committee on Child Health:

WHEREAS, the work of the Laconia State School is of great importance, both in the care of the individuals committed to it, and in the protection of the Communities from which such individuals come, and

WHEREAS, the facilities and personnel of the Laconia State School are inadequate to the need,

NOW, THEREFORE, BE IT RESOLVED That the New Hampshire Medical Society urges that the appropriation for the Laconia State School be increased sufficiently to provide adequate personnel and facilities, including a special pavilion for feeble-minded children under the age of five years,

AND BE IT FURTHER RESOLVED That a copy of this resolution be sent to the appropriate officers and committees of the General Court.

He moved the adoption of this resolution

This motion was duly seconded and was carried

The report of the Committee on Maternity and Infancy was then presented

The Committee has conducted an annual study of maternal deaths, infant deaths and stillbirths for fourteen years. The deaths studied in this report are those occurring during the calendar year 1947. This study, as all others in

the past, was conducted with the co-operation of the Department of Health, which gives the services of personnel in the divisions of Maternal and Child Health and Vital Statistics. That the Committee may review and study all facts concerning each case and render an unbiased decision, the Division of Maternal and Child Health, acting for the Committee, gathers all data, compiles pertinent facts, and presents the material to the Committee. In this way all information is kept confidential and the members of the Committee do not know the identity of the patient, physician reporting, hospital or community where the infant was delivered. It should be pointed out that a study of this kind is made possible only through the co-operation of the reporting physicians, who must furnish all the facts concerning the care of the patient and the events which lead up to the patient's death. The Committee realizes its responsibility in deciding how each case should be classified. As in the past, the Committee has endeavored to appraise the data as fairly as possible, making its decisions on the facts presented and knowing that it is much easier to decide the proper method of approach to a case after it is finished than it may have been for the physician who was attempting to perform the best possible conduct at the time when the patient needed it. It is the hope of the Committee that this report, as others in the past, may be helpful in pointing out in retrospect certain suggestions that future conduct in the handling of cases, presenting similar problems, may prove helpful.

It is with this thought in mind that the Committee wishes physicians to read the recommendations and suggestions made, with the hope that the comments may prove of future value.

In the event that copies of past maternal-death studies are not available, it seems desirable to include in this report a brief description of the method used by the Committee in conducting this study. After the data are gathered, either through personal contact by a member of the Department of Health or by letter, including a questionnaire, it is presented to the Committee without identifying information. Each member of the Committee has a copy of the information to study. The Committee then discusses the details of each case, weighs the facts and finally reaches a decision concerning the cause of death and the conduct of the case. The Committee in classifying the causes of death, in accordance with the facts, may differ from the classification as coded according to the International List of Causes of Death by the Division of Vital Statistics. The discrepancies in classification are due to the fact that the Committee has obtained as full information as possible concerning each case, whereas the Division of Vital Statistics must depend upon the recorded diagnosis of the physician as included on the death certificate. This year, for instance, one death, which was not coded by Vital Statistics as a maternal death, was so classified by the Committee. Although the death certificate mentioned that the patient at the time of death was pregnant, the cause was listed as paralytic ileus with intestinal obstruction, which, according to the code, takes precedence over the pregnancy. The Committee found that the intestinal obstruction followed a cesarean section, and it was therefore classified as a maternal death. However, the death was deemed due to surgical causes. On the other hand, the Committee assigned 4 cases to other causes, which were listed as maternal deaths by the Division of Vital Statistics in accordance with the International Code—namely, deaths due to anesthesia, diabetes and accidents.

In looking back over the years during which these studies have been performed, two important facts seemed to stand out. In the first place, there has been a very real and significant decrease in the maternal death rate over a period of fifteen years. This is true even in years in which the birth rate has been high. The lowest maternal death rate in New Hampshire is for the year 1947, and the number of births in the State has reached an all-time high. The second interesting fact is that, over the years, the causes of maternal deaths have been strikingly narrowed down to conditions that may be considered accidental and unavoidable. There was a time, not too long ago, when the causes of maternal deaths were due to glaring mistakes, poor obstetrics, infections or gross hemorrhages. Only a few years ago, the three chief causes of maternal deaths were puerperal sepsis, post-partum hemorrhage and toxemia of pregnancy, in that order. In 1947,

tributed to toxemia of pregnancy. This was one of 2 cases of toxemias reported. It is interesting that fewer toxemias of pregnancy were listed than in any previous year during which this study has been conducted. The Committee would like to believe that its efforts in outlining repeatedly its recommendations concerning the treatment of toxemia may in part be responsible for the decrease in the number of deaths due to toxemia. In 1946, or the year of the last report, the leading cause of death, in the cases studied was toxemia of pregnancy. In the past the Committee considered the treatment for toxemia as reported by physicians to be entirely inadequate. In a case reported in 1947 the patient was a twenty-two-year-old woman who, during her first pregnancy, received excellent prenatal care. During the last trimester, the patient's blood pressure started to rise. There was some albumin in the urine, and the patient was hospitalized on two separate admissions during which she received intensive treatment for toxemia. This consisted of the administration of adequate doses of intravenous magnesium sulfate and sedation. On the last admission when she went into labor, she received continuous therapy for the toxemia and after a trial labor was delivered by cesarean section. During the post-partum period, she was digitalized, given oxygen, kept under sedation and finally given a blood transfusion. About six and a half hours after the operation, however, the patient died. Autopsy revealed extensive damage to the liver indicating that the toxemia had been overwhelming. The Committee believed that, in all probability, the treatment had been adequate.

Two of the cases that the Committee classified in Group III were attributed to anesthesia. One of these occurred in an eighteen-year-old primipara who aspirated a large quantity of recently ingested material during a light nitrous oxide and oxygen anesthesia. The Committee considers it a wise precaution to choose carefully the type of anesthesia that is safest to administer under such circumstances. The other death in this group occurred approximately three quarters of an hour after the normal delivery of a child under spinal anesthesia. The physician was engaged in repairing an episiotomy when the patient, who had been gaily conversing, stopped talking, became cyanotic, lost consciousness, and suddenly died. There can be little doubt that this death was caused by the paralysis of the respiratory centers due to the anesthetic. It was not clear whether the patient was being attended by an anesthetist or not, but from what could be gathered the physician who performed the delivery also administered the anesthetic. The Committee believes that a spinal anesthetic, when it is chosen, should be administered by a physician trained in such techniques and by one who can be in constant attendance to the patient for purposes of checking blood pressure, pulse and respiration and can be at all times thoroughly observant of the patient's general condition. The physician who is delivering the patient cannot be in two places at the same time. It may be well at this point to comment about the third anesthetic death reported in 1947. This death was one of 2 deaths classified by the Committee in Group II. This case occurred during a normal spontaneous delivery in the course of which the patient suddenly ceased breathing and died despite the supposed efforts of resuscitation through administration of oxygen. After the death occurred, it was found that the nitrous oxide tank was attached to the auxiliary oxygen. This case thoroughly illustrates the importance and necessity of careful checking by the anesthetist of apparatus, tanks, patient and everything concerned before the anesthesia is induced as well as during the anesthesia. Because 3 of the 15 maternal deaths were considered due to anesthesia, the Committee believes that it should include in this report the opinion of the New England Society of Anesthesiology that was included in last year's report since repetition may sharpen the consciousness of physicians in the consideration of the importance of anesthesia.

There are so many dangers inherent in all types of anesthesia that the success and safety of all the various methods is directly proportional to the experience and training of the person responsible. These dangers are so numerous and serious accidents are so imminent that it is imperative for a physician to be in constant attendance throughout the entire administration.

Serious or potentially fatal complications are especially prone to occur during the course of intravenous anesthesia, spinal anesthesia and caudal analgesia. These accidents are usually preventable. It is our opinion that a physician conversant with these dangers should be in constant attendance.

Group I numbers 5 cases. This represents 33.3 per cent of the maternal deaths in 1947. Of these, 2 were due to abortions. One of these involved the criminal participation of two laymen, who were charged and found guilty and are serving prison sentences. The other was a self-induced abortion ending in the only case of puerperal sepsis reported. Causes of death of the other cases in this category were myocarditis in a patient with long-standing heart disease, who did not seek medical attention and a toxemia of pregnancy in a case in which no prenatal care was sought. One patient presented herself for the first time to the physician when in labor, and was found to have a marked and severe anemia. She died after delivery, followed by an excessive post-partum hemorrhage from a flaccid and atonic uterus. The Committee believes that the medical profession must continue an increased determination to educate the public concerning the importance and necessity of prenatal care.

### COMMENTS AND RECOMMENDATIONS

In the analysis of the 15 cases studied, it was shown that almost half, or 7 cases, were probably unavoidable. Five cases or one third, were due to the neglect of the patient herself. Since this is true, and since one third of the cases occurred in mothers who had had cesarean sections, admitting that most had reasonable indications and with 3 anesthetic deaths this year the Committee believes that the following recommendations should be made.

The Committee wishes to stress the importance and necessity for good prenatal care to ensure safe and logical planning for the conduct and method of delivery. It cannot stress too much the role of the physician, the nurse, public-health agencies and hospitals in making available to the public accurate information on facilities for prenatal care on a local and state level. Although efforts have always been made to educate the adult population concerning prenatal care, the Committee recommends that the private practitioner increase his efforts toward this end, and to assist in every way the efforts of both public and private agencies in the adequate and more intensive dissemination of information. The Committee wishes to enumerate the essential components of initial prenatal care. This should consist of a complete history, that a thorough appraisal of the patient's past, present and future status can be determined, a complete physical examination including a blood test, urine test and any other indicated laboratory tests and monthly return visits for the first six or seven months, after which more frequent visits should be made if indicated. The use of special diagnostic aids such as pelvic x-ray study should be employed if necessary.

The Committee wishes to stress the importance of anesthesia in obstetrics and recommends that the obstetrician obtain the services of trained anesthetists in assisting him with his deliveries. The Committee believes that physicians should be encouraged to acquire training in the skill of anesthesia.

The Committee believes that cesarean sections are performed too frequently without clear-cut or accepted indications. To say that the pelvis is contracted does not prove disproportion. It is true that physicians today may have adequate indication to do a cesarean section, since one may have been performed for a previous delivery. The Committee believes that sections should not be performed because the patient requests the surgical procedure, unless there is a definite indication for the operation. There is too much risk in choosing a surgical delivery for the purpose of sterilization. It is recognized that sterilization may be done at the time of the section when the latter is indicated.

The Committee wishes to comment on the encouraging increase in the number of autopsies performed in this

curred in 1933, about the time the maternal-death studies began. There was a slowly receding rate through 1942, but in 1943 there was a rise in the rate, which remained through 1944 and started to drop again in 1945. In the next two years, the drop in the rate seems to be tending toward a more rapid fall. In 1946 the number of births increased from 8551 in the previous year to 11,489. There were 16 maternal deaths reported in 1946, giving a maternal death rate of 1.4. In 1947 the year of this study, there were 15

tion and should be considered responsible for her own death. There was only 1 case in the undetermined group, for the Committee, in this case, could not determine from the facts what had caused the death of the patient. It may be interesting to review some of the facts in certain of the maternal deaths studied this year.

In Group IV, 1 patient was reported as having died of acute dilatation of the heart. The patient was a 38-year-old primipara who had a contracted pelvis. A planned cesarean

maternal deaths reported, and the number of births jumped to 12,912, which is an all-time high. The maternal death rate for 1947 is 1.1 per 1000 live births, an all-time low.

### MATERNAL DEATHS

There were 15 maternal deaths in 1947. The number of births was 12,912, giving a maternal death rate of 1.1 per

section was done at term, under spinal anesthesia and was completed with no incidents. Twenty-four hours after the operation, an intravenous injection of 5 per cent glucose in saline solution was administered. Almost immediately the patient had a chill, her temperature became elevated, and she died a little more than twenty-four hours after the section. Autopsy revealed nothing unusual, except what might have been expected after sudden death. The Com-

1000 live births. In conducting the study of maternal deaths, the Committee attempts to place each death in a specific classification or group according to where the responsibility seems to fall. To determine this classification the Committee carefully appraises all the facts and without bias places each case in one of the four groups listed above. The Committee is gratified that in 1947 the largest number of deaths were classed as unavoidable. The next largest group was assigned to the patient, who either did not seek prenatal care, refused treatment, or performed a self-inflicted abor-

mittee could not assign the death to acute dilatation of the heart, but from the facts presented, could not determine the cause of death.

The largest group, including 7 deaths, the Committee classified as unavoidable. This group of cases presents some interesting facts. These cases fell roughly into 3 groups, namely, deaths due to anesthesia, deaths due to surgical causes, one of which was uncontrollable bleeding and accidents of pregnancy, such as pulmonary embolism, and ruptured ectopic pregnancy. One of these deaths was at

The number of conjunctival petechiae increased. The temperature ranged from 102 to 103°F, and the pulse from 90 to 100, rising in the last twenty-four hours to 120. There was no other change in physical signs. On the sixth hospital day the patient died without regaining consciousness.

#### DIFFERENTIAL DIAGNOSIS

DR F DENNETTE ADAMS This case will be discussed from the standpoints, first of the underlying disease and second of the terminal illness. The history is not very helpful except that it seems to bring out clearly that the patient had a failing heart. The most likely cause of the sudden attack of weakness is concealed hemorrhage, since no mention is made of blood in the vomitus, hemorrhage, if it occurred, was below the duodenum or not in the intestinal tract at all. Pulmonary embolism is another possible cause of the episode of weakness. From the description of the murmur it seems reasonable to assume that cardiac enlargement and failure were due to aortic valvular disease. The character of the murmur—systolic in time, most marked at the second right interspace, widely distributed, transmitted to the neck and accompanied by palpable thrill—points definitely toward aortic stenosis. The murmur was louder than one ordinarily hears with atheroma of the aorta—with or without hypertension. Without knowing the previous blood-pressure level, we have no grounds for assuming that the patient ever had hypertension even though we recognize the fact that the current reading, 120 systolic, 80 diastolic, may not have represented the patient's true blood pressure, it may have been low for her because of failing myocardium or peripheral vascular failure secondary to the process causing the episode of weakness discussed above. There are three other possibilities to be considered in connection with the murmur—syphilis, rheumatic disease and calcareous aortic-valve disease. Syphilis is excluded. In syphilitic aortic disease sufficient to give so loud and extensive a systolic murmur, one would also hear a loud diastolic murmur. No mention is made of this. The negative blood Hinton test is another item of evidence against syphilitic aortic disease, it is almost always positive in cardiovascular syphilis. Without a definite history of previous rheumatic infection one cannot, with any degree of assurance, differentiate rheumatic aortic disease and calcareous disease, but on the law of probability I would vote for the latter. The patient was in the right age group, there was no history of rheumatic infection. Some authorities believe that calcareous aortic-valve disease is actually the end result of rheumatic disease. In this hospital I believe that it is regarded not as rheumatic but as an unusual arteriosclerotic manifestation. Is that correct, Dr Castleman?

DR BENJAMIN CASTLEMAN Not quite. It may well be a nonspecific infectious process, not necessarily rheumatic.

DR ADAMS In any event, I believe that the patient had calcareous aortic-valve disease. We may get help from the x-ray film, which sometimes shows calcium deposits in the leaflets, but failure to demonstrate them would not alter my opinion. The aortic second sound was not heard because the valve leaflets were fixed and did not snap shut as in the normal heart. It is harder to explain absence of the pulmonic second sound unless it was concealed by the very loud murmur. Theoretically, with left-sided failure and pulmonary congestion, back pressure on the pulmonic valve should make the pulmonic second sound louder than normal. The ankle edema could have been due to any one of several conditions: right-sided heart failure, thrombophlebitis or phlebothrombosis. If it was due to right-sided failure, one would expect a palpable, perhaps tender liver and distended neck veins. Varicosities are not mentioned, it seems probable that if the edema had been due to this disturbance it should not have been so pronounced after some days in bed. Thrombotic disease of the leg veins is favored by congestive failure and inactivity of the patient. One cannot with certainty explain the signs in the lungs but only mention the probabilities: congestive failure, pneumonia, pulmonary infarction or any combination of these. The x-ray film may help us decide, but often the roentgenologist cannot be sure either.

The urinary examination is consistent with congestion or perhaps, as we will see later, with infection or both. The findings do not necessarily indicate a primary nephritis. The blood picture indicates acute infection. Perhaps Dr Wyman can help us out with the lungs.

DR STANLEY M WYMAN The mottling in the right lung is more pronounced in the lower portion. There is some in the upper lobe as well. The left-lung field is relatively spared, but there is some mottling in the left base. This film was taken with the patient lying on her back, and the heart shadow cannot be measured in terms of cardiothoracic ratio, the heart appears to be prominent in the region of the left ventricle, dipping down below the diaphragm, and is prominent to the right as well. The aorta is tortuous, arising at this point and extending far to the right, explaining why the murmur was heard so far to the right. Calcification is visible in the arch. The lateral view shows the heart to extend rather far posteriorly in the chest. It is definitely increased in the anteroposterior diameter, suggesting that the patient has been a victim of emphysema and fibrosis for some time. This shadow suggests enlargement of the left auricle. The hilar vascular shadows seen on the left do not appear unusually prominent.

year's series of deaths. It wishes to encourage this practice that actual causes of death may be verified and properly classified.

The Committee is confident that the drop in post-partum infections as a cause of death has come to stay. The only infections reported in cases in this series were due to neglect on the part of the patient or to criminal interference. It may be anticipated that infection as a cause of death in maternity will disappear.

The Committee would like to comment concerning the stillbirth rate and infant death rate for 1947 by pointing out that these rates have reached an all-time low. The stillbirth rate for 1947 was 21.5 per 1000 live births. The infant death rate for 1947 was 28.1 per 1000 live births, or slightly lower than the rate for 1946, which was 28.7 per 1000 live births. However, it should be noted that up to 1944, the infant mortality rate was as high as 37 per 1000 live births.

Since there were 9 stillbirths reported as due to erythroblastosis and since there may have been many more, the Committee would like to include in its recommendations a statement concerning the importance of the Rh factor in obstetrics. In cases in which the mother is Rh— and the father is Rh+, danger may exist for the fetus, in that fatality may occur two or three weeks before term or shortly after birth from erythroblastosis and hemolytic jaundice.

The Committee stresses that it is important that laboratory facilities throughout the State provide the means of determining the presence of this factor in the mothers' blood prenatally, that the possibility of such danger may be foreseen. Occasionally a stillbirth will occur that is perhaps preventable.

The Committee recommends that mothers be tested for Rh factor and that when such fetuses are born they be carefully watched for the development of severe hemolytic jaundice and a marked drop in the red cells, and that treatment be available in the form of transfusion from an Rh— donor, accurately typed and cross-matched.

The Committee wishes to thank all physicians and hospitals responding to the requests for information that was necessary to conduct this study and to make a report. As in the past the Committee wishes to state that any recommendations or suggestions from the physicians throughout the State will be welcome.

The Committee wishes to acknowledge with appreciation and co-operation of the Department of Health through its Divisions of Maternal and Child Health and Vital Statistics in furnishing data and personnel in the preparation of this report.

ROBERT O. BLOOD, M.D., *Chairman*  
BENJAMIN P. BURPEE, M.D.  
JAMES SANDERS, M.D.

Dr. Sycamore moved that the recommendations of the Committee be approved.

This motion was duly seconded and was carried.

#### CASE 34441

##### PRESENTATION OF CASE

An eighty-year-old widow was admitted to the hospital complaining of weakness.

The patient had been in slight congestive failure about six weeks previously and had taken digitalis since that time. One month prior to admission she had a severe respiratory infection, from which she apparently recovered except for a persistent cough. Four hours prior to admission, while preparing supper, she experienced a sudden attack of weakness, was nauseated and vomited. She was seen by a physician, who referred her to the hospital.

Physical examination revealed the heart to be enlarged, the border of cardiac dullness extending 11 cm. to the left of the midsternal line in the fifth interspace. A rough, Grade IV systolic murmur with an associated thrill was present, most marked in the second interspace, 7 cm. to the right of the midsternal line. The murmur was widely transmitted,

both to the neck and over the whole chest anteriorly. Neither the aortic nor the pulmonic second sound could be heard. Rales were present at both bases posteriorly, particularly on the right, where there was a small area of bronchovesicular breathing. The liver was not palpated. Marked edema of the ankles was present. The left knee jerk was more active than the right.

The temperature was 104°F, the pulse 100, and the respirations 30. The blood pressure was 120 systolic, 80 diastolic.

Examination of the blood disclosed a white-cell count of 26,300, with 85 per cent neutrophils, 3 per cent lymphocytes, 10 per cent monocytes and 2 per cent late myelocytes. Frequent band forms were observed. Urinalysis showed a specific gravity of 1.024 and a ++ test for albumin, with occasional casts, 40 red cells and 25 white cells per high-power field in the sediment. The blood Hinton test was negative. X-ray examination revealed the heart to be enlarged in the region of the left ventricle. The aorta was tortuous and calcified. The right leaf of the diaphragm was slightly elevated and poorly defined, owing to poor aeration of the right lower lobe. The right lower lobe showed some diffuse and mottled increased density with one larger patch. The left lung appeared normal.

On the third hospital day the patient was "drowsy but responsive," and petechiae were observed on the conjunctivas. The temperature continued elevated, and a blood culture showed a growth of *Staphylococcus aureus* on two occasions. She gradually became unresponsive and then comatose. On the fifth hospital day it was possible to demonstrate a flaccid paralysis of the left arm and leg.

DR ADAMS I cannot rule out either one with certainty. On the law of probability a murmur of this type in an eighty-year-old woman is more likely due to aortic calcareous disease than to rheumatic disease. As I said at the outset, some observers believe that calcareous aortic disease is the end result of rheumatic disease. Conceivably, such a murmur could be due to a congenital bicuspid aortic valve, with superimposed calcareous disease.

#### CLINICAL DIAGNOSES

Calcific aortic stenosis  
Acute bacterial endocarditis  
Cerebral emboli

#### DR ADAMS'S DIAGNOSES

Calcareous aortic stenosis, with hypertrophy and dilatation of heart  
Acute bacterial endocarditis of aortic valve  
Generalized septicemia (*Staph aureus*)  
Multiple septic infarcts of brain, lungs, kidneys, spleen and perhaps other viscera  
Thrombophlebitis of leg veins?

#### ANATOMICAL DIAGNOSES

*Endocarditis acute, bacterial, aortic calc* (*Staph aureus*)  
*Calcific aortic stenosis*  
*Mycotic aneurysm, left circumflex coronary artery, with rupture*  
Hemopericardium  
Infarcts, septic, of spleen, kidney and brain  
Bronchitis, acute, purulent  
Pulmonary edema  
Pulmonary fibrosis, right

#### PATHOLOGICAL DISCUSSION

DR CASTLEMAN This patient did have calcific aortic stenosis. The cusps were thickened with the calcareous deposits in the sinuses of Valsalva, which is in contrast to what is seen in the rheumatic heart. In the true rheumatic heart stenosis is produced by interadherence between the cusps, whereas in this type of case stenosis is more apt to be produced by calcareous masses within the sinuses of Valsalva. There was a vegetation on the aortic valve and also one on the mitral valve.

DR ADAMS But not a large one?

DR CASTLEMAN No.

A PHYSICIAN Would you not have expected a murmur in the mitral region?

DR ADAMS That could have been obscured by the aortic murmur.

DR CASTLEMAN The pericardial cavity contained about 200 cc of blood, and on the epicardium were shreds of blood clot. Along the course of the circumflex branch of the left coronary artery was a huge, very red, bulbous mass. Careful dissection of this area revealed a tear in this mass, which proved to be a mycotic aneurysm. I am certain

that this tear was the cause of the sudden attack of weakness. It is not the same as ruptured heart that produces death suddenly because of cardiac tamponade. Here the opening from the coronary artery was enough to fill the pericardial sac partially but not to balloon it out to produce sudden tamponade. As might have been expected, there were septic infarcts of the kidney, of the spleen and also of the liver, which is not too common. The bronchi were filled with polymorphonuclears but there was no acute pneumonia anywhere. There was some edema, but most of the process seen in the lungs was due to fibrosis. The patient had long-standing fibrosis with slight bronchiectasis as a result of scarring, especially marked in the right lower lobe, but also present in the right middle and upper lobes. The infections four years previously were probably just exacerbations of an old chronic, fibrotic process.

DR WYMAN How about the aorta?

DR CASTLEMAN It was tremendously dilated and arteriosclerotic, and showed calcification in the descending portion, not in the ascending portion. This absence of arteriosclerosis in the ascending aorta is almost the rule with calcareous aortic stenosis, and is one of the arguments that is used against believing that the valvular process is arteriosclerotic. When arteriosclerosis affects the ascending aorta one has to think of syphilis.

DR ADAMS The head was not examined?

DR CASTLEMAN Yes, it was, we found an infarct of the right parietal lobe that caused the terminal symptoms, and, in addition, numerous small septic infarcts were noted throughout the brain.

A PHYSICIAN Did an electrocardiogram show any coronary-artery involvement?

DR CASTLEMAN The patient was too sick. No electrocardiogram was taken. Until the blood cultures became positive on the fourth day she really had not been given all the penicillin possible — only 30,000 units every three hours; the dose was doubled on the fourth day.

#### CASE 3442

#### PRESENTATION OF CASE

*First admission* A forty-five-year-old woman, a telephone operator, was seen in the Emergency Ward because of painful swollen legs.

The patient had experienced bouts of ankle and lower-leg swelling for the past ten years, each attack lasting one to six weeks. This swelling disappeared after she stopped working. Three months before entry she had an initial attack of palpitation and

DR ADAMS Can you see calcification in the aortic-valve leaflets?

DR WYMAN This film is not good enough to make such an observation. If a heavy film had been taken, with the patient rotated so that the aortic-valve area, which lies here, were away from the spine, we might have seen it better. There is a suggestion of an area of density at this point where the aortic valve might lie, but it is not sufficient for me to say that it is calcification. The heart is shifted to the right, the right lung is definitely underaerated. This shadow shows tortuosity of the aorta.

DR ADAMS Just a large aorta?

DR WYMAN Yes. The ascending portion is wide.

DR ADAMS With this degree of widening of the aorta, one must think of aneurysm, but aortic arteriosclerosis and calcareous aortic disease are much more likely.

Having committed myself to a diagnosis of the primary disease, I must now explain the terminal events. The fever and leukocytosis indicate serious acute infection. With a history of recent respiratory infection, followed by persistent cough and signs of trouble in the lungs, one would first postulate lobar or bronchopneumonia. The conjunctival petechiae strongly suggest septicemia, and the report of two blood cultures positive for *Staph aureus* confirm this diagnosis. Septicemia occurring in a patient with valvular heart disease usually means endocarditis, *Staph aureus* infection is an acute fulminating disease, and endocarditis, if present, is acute. In the absence of any other portal of entry, such as a furuncle or other local abscess, it seems reasonable to assume that the staphylococcus entered through the respiratory tract, implanted itself on the chronically damaged heart valve and established an acute bacterial endocarditis, which, in turn, gave rise to multiple septic emboli. One could postulate that the loud murmur was due to the presence of a large vegetation on the valve, but only if it were known that the murmur had not been there previously or that a previously existing murmur had changed appreciably within the past few days. Lacking this information, it seems wiser to suppose that the murmur was due to calcareous disease. If we assume the presence of a septic vegetation on the heart valve, it is easy to explain the other terminal findings. Multiple septic emboli would account for the neurologic signs, — inequality of knee jerks on initial physical examination and the subsequent left-sided paralysis, — the urinary findings, especially the red cells and white cells, and the pulmonary signs.

To summarize, I believe this patient had calcareous disease of the aortic valve, with superimposed acute vegetative endocarditis on the valve, and multiple septic emboli involving the brain, kidneys, lungs and perhaps other organs, notably the spleen, and that she died of the septicemic

process. Thrombophlebitis of the legs cannot be excluded, but there is no definite evidence that it existed.

DR CASTLEMAN One does not usually see septic infarcts in the lung with a bacterial endocarditis unless they are coming from the right side of the heart.

DR ADAMS I am not certain, but it seems to me that I have seen cases of acute septic endocarditis in which septic infarcts have been found on both sides of the circulatory system and that one does not necessarily have to presuppose damage on the right side of the heart to get trouble in the lungs. One could also postulate emboli arising in the legs as the cause of the pulmonary signs.

DR CASTLEMAN That would be all right.

DR ADAMS In generalized pyemia cannot one find embolic abscess on both sides?

DR CASTLEMAN One can get abscesses in the lung with generalized septicemia.

DR ADAMS That is just what I am talking about.

DR CASTLEMAN What caused the sudden attack of weakness four hours before admission?

DR ADAMS I cannot answer that question. A certain number of old people who get severe infection do get sick terribly suddenly, and this may be the answer. Earlier in the discussion I stated that a sudden attack of weakness is most likely due to hemorrhage, but here we have no evidence on which to base a diagnosis of hemorrhage. A third possibility would be a pulmonary embolus.

A PHYSICIAN How about involvement of the coronary vessels?

DR ADAMS Yes. An embolus breaking off the aortic valve and landing in a coronary vessel might have caused the episode.

DR CASTLEMAN One almost always finds tiny emboli in the small coronary vessels, and Buchbinder and Saphir<sup>1</sup> believe that the miliary infarcts that develop are sufficiently numerous to produce real heart failure. In a series of 40 autopsied cases of subacute bacterial endocarditis, they found evidence of heart failure in 45 per cent. On the other hand, de Navasquez,<sup>2</sup> admitting the finding of miliary myocardial infarcts in subacute bacterial endocarditis in 95 per cent of the cases, was unable to demonstrate any relation with heart failure. Now that so many of these cases are being treated successfully, the healed miliary infarcts may become an important factor in the development of heart failure.

DR ADAMS This patient certainly presented the picture of infection rather than heart failure from the standpoint of the terminal illness. I believe that the infection was generalized septicemia.

A PHYSICIAN I still cannot see how a rheumatic heart can be ruled out completely. It is true that this was not a classic picture of rheumatic heart disease. I wonder also how you rule out congenital heart disease.

DR ADAMS I cannot rule out either one with certainty. On the law of probability a murmur of this type in an eighty-year-old woman is more likely due to aortic calcareous disease than to rheumatic disease. As I said at the outset, some observers believe that calcareous aortic disease is the end result of rheumatic disease. Conceivably, such a murmur could be due to a congenital bicuspid aortic valve, with superimposed calcareous disease.

DR CASTLEMAN That would be all right.

DR ADAMS In generalized pyemia cannot one find embolic abscess on both sides?

DR CASTLEMAN One can get abscesses in the lung with generalized septicemia.

DR ADAMS That is just what I am talking about.

DR CASTLEMAN What caused the sudden attack of weakness four hours before admission?

DR ADAMS I cannot answer that question. A certain number of old people who get severe infection do get sick terribly suddenly, and this may be the answer. Earlier in the discussion I stated that a sudden attack of weakness is most likely due to hemorrhage, but here we have no evidence on which to base a diagnosis of hemorrhage. A third possibility would be a pulmonary embolus.

A PHYSICIAN How about involvement of the coronary vessels?

DR ADAMS Yes. An embolus breaking off the aortic valve and landing in a coronary vessel might have caused the episode.

DR CASTLEMAN One almost always finds tiny emboli in the small coronary vessels, and Buchbinder and Saphir<sup>1</sup> believe that the miliary infarcts that develop are sufficiently numerous to produce real heart failure. In a series of 40 autopsied cases of subacute bacterial endocarditis, they found evidence of heart failure in 45 per cent. On the other hand, de Navasquez,<sup>2</sup> admitting the finding of miliary myocardial infarcts in subacute bacterial endocarditis in 95 per cent of the cases, was unable to demonstrate any relation with heart failure. Now that so many of these cases are being treated successfully, the healed miliary infarcts may become an important factor in the development of heart failure.

DR ADAMS This patient certainly presented the picture of infection rather than heart failure from the standpoint of the terminal illness. I believe that the infection was generalized septicemia.

A PHYSICIAN I still cannot see how a rheumatic heart can be ruled out completely. It is true that this was not a classic picture of rheumatic heart disease. I wonder also how you rule out congenital heart disease.

lar 270 There were multiple ventricular ectopic beats

Four days after admission the patient was started on puriodigin and ammonium chloride. This was followed by nausea and vomiting, which became progressively worse. This therapy was stopped two days later. The nausea and vomiting persisted for five days after the digitalis had been withheld. At this time the patient showed a questionable slight sacral edema and a slight nonpitting edema of the stumps. The lungs were dry. There was great and frequent variation in the degree of pulse deficit. The apical pulse rate was 120 and grossly irregular and the radial pulse 45. On the thirteenth hospital day the patient was given cedilanid intravenously after which the nausea stopped. This was continued for four days, and then puriodigin again begun. One day later, the pulse had slowed and was regular, with rare extrasystoles. She no longer had a pulse deficit. An electrocardiogram taken on the following day disclosed a normal rhythm with a rate of 95.

With the exception of a short period of bigeminal rhythm, the patient remained improved symptomatically for the next eight days. On the twenty-seventh hospital day, however, she suddenly developed a severe, sharp pain in the lower anterior portion of the right side of the chest. Physical examination of the chest was negative, the pain was relieved by 75 mg of demerol subcutaneously, and the patient did not look acutely ill. Half an hour later, however, the blood pressure and pulse were unobtainable. The skin was cold and sweaty but not cyanotic. There were scattered coarse rales in both lungs.

The patient remained in collapse for two or more hours. She gradually showed improvement, however, and six hours later the blood pressure was 105 systolic, 80 diastolic. The pulse was good and regular. An electrocardiogram revealed the presence of an infrequent fusion beat.

The patient suffered a similar episode of shock on the following day, from which she again recovered. On the afternoon of the next day she asked for the oxygen mask, having no definite complaints but saying that she "felt scared." Half an hour later she was found breathing very rapidly and gasping for breath. She became cyanotic and died a few minutes later.

#### DIFFERENTIAL DIAGNOSIS

DR HOWARD B. SPRAGUE This is a rather peculiar story, as usual in these exercises. At the age of thirty-five the patient began to have attacks of edema of the ankles and lower legs, relieved by rest. These attacks lasted from one to six weeks. There does not seem to have been any history of dyspnea at that time, and one wonders whether the sedentary occupation of telephone operator, rather than a cardiac condition, led to the development

of edema of the legs. Of course, swelling of the legs, as studied in patients in the Out-Patient Department, is more commonly not due to heart disease than due to heart disease, but we do have evidence as we go along that there was something wrong with this patient's heart. She apparently had some venous difficulty with the legs, and it was not particularly related to the final disease. However, ten years later, she began to have palpitation, swelling of the ankles and what was probably ectopic rhythm, auricular fibrillation. These attacks recurred and were relieved by cardiac therapy, at least so far as the edema is concerned. Previously, this had been alleviated by stopping work, but now digitalis and mercurials were necessary. The sudden onset six days before admission consisted of an attack of interference with circulation of the legs. By the time of admission there were cyanosis, pain and tenderness and some swelling and gangrene of the feet and absence of arterial pulsation. From the fact that cyanosis was present and from what I interpreted as some pulsation of the femoral arteries, I judge that this was a partial occlusion of the circulation, presumably at the bifurcation of the iliac vessels or above. The electrocardiogram suggested some left, or at least the absence of right, ventricular strain pattern. The blood pressure was somewhat elevated, the diastolic pressure was 110, and the heart was enlarged to the left.

What about this red herring of the one attack of crushing pain in the chest? When did she have that? Can anyone answer that? Was it in relation to this episode in which the circulation of the legs was obstructed, or was that something that occurred some time in the past? We do not know.

The second admission, three and a half months later, seems to have been that of a person with cardiac difficulty, and therapy was hard to manage. There was some evidence of digitalis intoxication, such as bigeminy, and the cardiac findings were those, presumably, of some pulmonary hypertension. The pulmonic second sound was accentuated, and there was a definitely enlarged heart to the left.

Are the x-ray films available?

DR JAMES J. MCCORT Yes. This film of the chest was made at the time of the first admission. The heart is definitely enlarged to the left and most likely represents enlargement of the left ventricle. The pulmonary vascular markings are within normal limits. The aorta is not tortuous or sclerotic. Both lungs are clear, there is no fluid in the costophrenic sinuses. This next chest examination, three and a half years later at the time of the third admission, shows a large heart, again with enlargement to the left. The lungs are clear and no fluid can be demonstrated in the costophrenic sinuses. On the third examination made three weeks after the third admission, the heart is unchanged in size, but there is some accentuation of the vascular markings as compared with the previous examination.

nervousness associated with swelling of the ankles. Such attacks recurred with almost any form of exercise. At about this same time she was told that she had heart disease and was given digitalis and mercupurin, after which the edema disappeared. Six days before admission the legs suddenly became blue, cold and painful. She never had orthopnea or cough but did have one attack of pain in the upper chest, crushing in character. She denied having any history of heart disease when young.

On physical examination the heart seemed to be enlarged to the left, the rhythm was regular. An inconstant gallop with frequent extrasystoles and a very soft systolic murmur were heard at the apex. The legs were swollen, bluish and tender, the feet were gangrenous. There was no arterial pulsation below the femoral arteries.

The blood pressure was 154 systolic, 110 diastolic.

An electrocardiogram showed a normal rhythm at a rate of 90, a PR interval of 0.19 second, low upright T waves in Leads 1 and 2 and a flat T wave in Lead 3, there was slight slurring of the QRS complexes and a tendency to left-axis deviation. The T waves were upright in Lead CF<sub>2</sub>, low upright in Lead CF<sub>4</sub>, and flat in Lead CF<sub>3</sub>, the R wave was low in Lead 4.

Bilateral low-thigh amputations were done, followed two days later by bilateral ligations of the common femoral veins. The patient was placed on a cardiac regime and discharged twenty-one days after admission feeling well.

*Second admission* (approximately three and a half months later). In the interval the patient was followed in the Out-Patient Clinic, where she complained of intermittent nausea, vomiting, palpitation and swelling of the stumps. An electrocardiogram showed bigeminy and other findings interpreted as digitalis effect.

Physical examination revealed the heart to be enlarged, the point of maximal intensity being 13 cm to the left of the midsternal line in the sixth interspace, it was diffuse and forceful. There was a Grade I apical systolic murmur, which was not transmitted. The pulmonic second sound was split and markedly accentuated. There was no gallop rhythm. The liver edge was not palpable. There was slight pitting edema of the stumps.

The blood pressure was 150 systolic, 100 diastolic.

The blood and urine were not remarkable. The nonprotein nitrogen was 30 mg, and the total protein 7.3 gm per 100 cc, with 4.92 gm of albumin and 2.38 gm of globulin. A blood Hinton test was negative. The circulation time with calcium gluconate was twenty seconds (arm to tongue) and with ether, ten seconds (arm to lung). The venous pressure in the antecubital vein 10 cm above the posterior axillary line was equivalent to 11.75 cm of water. The vital capacity was 2.8 liters, or 82 per cent. An electrocardiogram showed

bigeminy in Leads 1 and 4, with ventricular premature beats occurring after each normal beat. The axis was normal. The T waves were flat in Leads 1 and 4 and inverted in Leads 2 and 3. The ST segments were sagging in Leads 2 and 3. Digitalis was withheld for two weeks, transient bouts of bigeminy persisted, however. Edema of the stump was absent at the end of this time. Digitalis was reconstituted in small doses, and the patient was discharged.

*Final admission* (approximately three and a half years later). Following the second hospitalization, the patient showed marked progressive improvement on very limited activity. The pulse was regular, the murmur previously heard disappeared, and she suffered no shortness of breath or edema. One month before entry she developed nausea and slowly progressive swelling of the stumps and abdominal wall. She had only rare vomiting. The nausea was not associated with pain or diarrhea and diminished somewhat during the following two weeks. At that time, however, two weeks before admission, she noted dyspnea and orthopnea. Four days later she experienced a severe episode of sharp substernal pain, which "took her breath away." She was given an injection by a physician, which brought about relief ten minutes after the onset of pain. The nausea persisted, and there was progressive edema, dyspnea, orthopnea and weakness. She had no digitalis during the two weeks before admission.

Physical examination revealed a well developed, well nourished woman, who was comfortable on two pillows. The abdominal wall, sacrum and stumps appeared full but showed very little pitting. The skin was moist, and there was no evidence of cyanosis. The apex of the heart was 13 cm to the left of the midsternal line in the sixth interspace. The sounds were distant. There was a Grade II systolic murmur, heard best just to the left of the sternum. The pulmonic second sound was greater than the aortic second sound. There were numerous extrasystoles. The liver edge was slightly tender and was felt two fingerbreadths below the costal margin.

The temperature was normal, the pulse 110, and the respirations 24. The blood pressure was 120 systolic, 82 diastolic.

Laboratory study disclosed a prothrombin time of 20 seconds (control, 16 seconds). The nonprotein nitrogen was 44 mg, the total protein 5.6 gm, and the cholesterol 208 mg per 100 cc, and the sodium 136.7 milliequiv per liter.

A roentgenogram showed the heart grossly enlarged, the cardiothoracic ratio being 175.24/0. The left-lower-lung field was almost entirely obliterated by the overlying heart shadow.

An electrocardiogram done on the day following admission was interpreted as showing auricular flutter, the ventricular rate was 120, and the auricu-

aortic second sound was less than the pulmonic I think that she had had an embolus at the bifurcation of the aorta, presumably an embolus arising from the heart. But other sources can be the aorta itself, and extremely rarely the pulmonary veins. Just for the dubious credit of having mentioned dissecting aneurysm of the aorta, I think I should put it in but with several question marks.

DR EDWARD F. BLAND: Let us ask Dr Gephart if he would comment on why the common femoral iliac veins were tied following low amputation. Was that to ensure circulation locally or was it a preventive measure?

DR F. THOMAS GEPHART: It was a preventive measure. At amputation a few years back, although we still do it occasionally, we more frequently tied the common femoral veins to prevent pulmonary embolism from the stump. It was purely a protective measure.

DR MALLORY: Have you any comment on the cardiac disease, Dr Bland?

DR BLAND: No, but I am not sure what Dr Sprague's final diagnosis is.

DR SPRAGUE: I would have to call it hypertensive heart disease for want of a better diagnosis.

DR BLAND: This case was a puzzle, as you see — it may still be after Dr Mallory presents his findings.

DR RICHARD J. CLARK: Where does Dr Sprague think the terminal emboli came from? If there were terminal pulmonary emboli, what was the source?

DR SPRAGUE: Presumably in the venous system above where they ligated.

DR BLAND: For the sake of the record I think it is correct that Dr Paul D. White saw the patient some time before the final admission, and he, like the rest of us, was puzzled but decided that she had heart disease of undetermined cause, or perhaps she belonged to the small group of cases that Dr Mallory may have trouble in deciding about too.

#### CLINICAL DIAGNOSES

Myocarditis of unknown etiology?

Pulmonary embolism

#### DR SPRAGUE'S DIAGNOSES

Cardiac disease of unknown etiology (hypertensive?)

Embolism to bifurcation of aorta

Terminal pulmonary embolism

#### ANATOMICAL DIAGNOSES

Hypertrophy and dilatation of heart, generalized

Coronary arteriosclerosis with occlusion, descending branch of right coronary artery

Infarct of right ventricle

Mural thrombi of right auricle and right ventricle

Pulmonary emboli, multiple, with infarction

Amputation of legs

#### PATHOLOGICAL DISCUSSION

DR MALLORY: There is a comment in the record by Dr White three years ago, suggesting the probability of idiopathic myocarditis of the type described by Levy.\* I think, as in so many of these clinically difficult cases, the problem remains difficult after autopsy. I can only tell you what we found. The heart was very diffusely enlarged, in both right and left ventricles. We were particularly impressed by the enlargement in the right ventricle. There were thrombi present in the right auricle and numerous thrombi overlying the endocardium in the right ventricle. There were some gross foci of scarring in the right ventricle. The large coronary branches were relatively free from atheroma, but looking over the heart a second time we demonstrated an occlusion of one of the terminal branches of the right coronary artery. Microscopical sections from the right ventricle showed an area of infarction, underlying the thrombus. Sections of the left ventricle revealed only a spotty fibrosis, with nothing to suggest infarction. The aorta showed a rather minimal degree of arteriosclerosis. We found absolutely nothing in the left side of the heart to provide a focus for systemic embolism. Of course, that embolism occurred four years previously. The endocardium of the left ventricle was a little thick. It is possible that there was thrombosis at one time, most of which broke off, and the fibrous healing of the remainder showed only as a thickened endocardium. The patient had numerous pulmonary infarcts for which there were two sources — the right auricle and the right ventricle — so I do not believe we have to assume that she had further trouble in the remainder of the iliac veins. The amputated legs showed complete thrombotic occlusion of the popliteal vessels. About a month before death she had a rather definite episode of gnawing, substernal pain, and the infarct in the right ventricle was histologically compatible with that duration. I think those two episodes can be put together — first cardiac infarction and then pulmonary embolism secondary to the intracardiac thrombosis. We have no etiologic explanation for the diffuse hypertrophy of the heart. As Dr Sprague suggests, it may have been hypertensive heart disease, although the hypertension was not very convincing in the later period of life, or as Dr White suggested, it was at some earlier period an idiopathic enlargement of the heart, which we can no longer prove.

DR SPRAGUE: Was there a separate embolus in each popliteal artery, or was it a thrombotic process?

DR MALLORY: The emboli were apparently separate, we do not know.

\*Levy, R. L., and von Glahn, W. C. Cardiac hypertrophy of unknown cause: study of clinical and pathologic features in 10 adults. *Am Heart J* 28:714-741, 1944.

These last two films, on the day before death and on the day of death, are taken with the patient lying down and are not too satisfactory. However, there is a suggestion of an area of slightly increased density in the right perihilar region and a smaller one in the right-lower-lung field. They may represent infarcts, but that is difficult to determine because of slight motion.

**DR. SPRAGUE:** The patient had improved for three and a half years. She had no legs, so she could not be very active presumably, and there was not too much test of her cardiac function. Auricular flutter was present on the third admission. I neglected one note about the second admission that the renal findings do not suggest an underlying kidney disease or an ischemic condition in the renal circulation. To return to the third admission, the patient had auricular flutter, a month of progressive edema of the leg stumps and the abdominal wall and, for the first time, dyspnea and orthopnea. She had the attacks of sharp pain in the chest, which suggest pulmonary embolism, the systolic murmur reappeared, the pulmonic second sound remained accentuated, the blood pressure was normal, and she had a very large heart. The auricular flutter was restored to normal rhythm, perhaps through temporary auricular fibrillation, which is the classic course in these cases. The lungs on physical examination were noted as being dry, but that probably was not true in the terminal films. I think that she presumably did have a terminal pulmonary embolism.

We should now consider the question of the underlying situation. If we start at the periphery of this patient, with the gangrenous feet, and go toward the heart, we have three possibilities to consider. The first is peripheral vascular disease, but it would be extraordinary for two thrombi to develop simultaneously in the two legs. It would be less extraordinary, but still unusual, to have simultaneous emboli to both legs. Therefore, it seems more reasonable to assume that the obstruction was higher up, presumably at the bifurcation of the iliac veins or higher. A rider embolus at the iliac bifurcation one often diagnoses by listening to the heart and finding mitral stenosis. There did not seem to be mitral stenosis in this patient, however. In no way can we bring in mitral stenosis unless we pick it out of the dark and say that there are some patients who have no murmurs with mitral stenosis. There is no evidence that this patient had had a coronary occlusion to give a basis for an intracardiac thrombosis. Is there anything further about the history of chest pain?

**DR. TRACY B. MALLORY:** On the final admission just before the shock-like episode, she had two sharp attacks of pain on the right side of the chest along the costal margin. Before the amputation she had complained of attacks of pounding of the heart but not of pain.

**DR. SPRAGUE:** We do not know about any attack of pain before amputation. The patient did not have

the shock or the abdominal pain that is usually associated with a large embolus to the iliac bifurcation, but she had a large heart, as well as auricular fibrillation, premature beats and auricular flutter, and she could have had an intracardiac thrombosis on that basis. How about primary thrombosis of the aorta, acute or slowly progressive? This history is pretty much against the picture of slowly progressive aortic thrombosis because there was no history of previous intermittent claudication. This was a sudden episode, whereas in the slowly occluding cases, according to the literature, there is in general either extensive ulcerative arteriosclerosis of the aorta or embolism to the bifurcation. It has been reported following irradiation of the pelvis. However, gangrene is very rare in slowly occlusive aortic thrombosis. Another part of that picture is the late appearance of hypertension due to involvement of renal circulation following occlusion of the aorta and later infarction of the kidneys. Acute thrombosis of the aorta, I suppose, might be a possibility, but this woman became extraordinarily well for three and a half years after amputation of both legs, which seems to me to be against a process that would by itself probably continue occluding vessels higher up.

One has to mention dissecting aneurysm because there was a history of a crushing pain in the chest and because dissecting aortic aneurysm, which has ruptured back into the lumen and caused a double-barreled aorta, turns up at autopsy every so often. But I think we must assume some degree of thrombosis of the aorta in addition. By the time of admission, apparently, the Surgical Service did not believe that the patient was a candidate for embolectomy or anything except amputation. Dissecting aneurysm of the aorta has often been confused, even here, with a rider embolism, and embolectomy has been attempted. But in this case there was no history of pains in the back or in the arms, or suggestion of obstruction to other branches of the aorta. One ought to mention, I suppose, ball or mass thrombus of the left auricle, because peripheral gangrene occurs in that condition. There are no cases, however, due to tumor of the auricle, and, so far as I know, only 1 case in the absence of mitral stenosis. But with mitral stenosis the patient would have had cyanosis, obvious rheumatic heart disease, auricular fibrillation and ischemic involvement of the arms and perhaps of the ears and tip of the nose due to obstruction of the mitral orifice, and she would not have become so well for three and a half years. So I do not know what type of heart disease this was, unless it was hypertensive heart disease, and I cannot make out any type of congenital anomaly or any valvular disease.

I would not like to be caught with one of these cases of aortic stenosis that keep turning up at these conferences. This patient was a young woman instead of an old man as is usually the case in that condition, and there is not much to go on. The

aortic second sound was less than the pulmonic I think that she had had an embolus at the bifurcation of the aorta, presumably an embolus arising from the heart. But other sources can be the aorta itself, and extremely rarely the pulmonary veins. Just for the dubious credit of having mentioned dissecting aneurysm of the aorta, I think I should put it in but with several question marks.

DR EDWARD F. BLAND: Let us ask Dr Gephart if he would comment on why the common femoral iliac veins were tied following low amputation. Was that to ensure circulation locally or was it a preventive measure?

DR F. THOMAS GEPHART: It was a preventive measure. At amputation a few years back, although we still do it occasionally, we more frequently tied the common femoral veins to prevent pulmonary embolism from the stump. It was purely a protective measure.

DR MALLORY: Have you any comment on the cardiac disease, Dr Bland?

DR BLAND: No, but I am not sure what Dr Sprague's final diagnosis is.

DR SPRAGUE: I would have to call it hypertensive heart disease for want of a better diagnosis.

DR BLAND: This case was a puzzle, as you see — it may still be after Dr Mallory presents his findings.

DR RICHARD J. CLARK: Where does Dr Sprague think the terminal emboli came from? If there were terminal pulmonary emboli, what was the source?

DR SPRAGUE: Presumably in the venous system above where they ligated.

DR BLAND: For the sake of the record I think it is correct that Dr Paul D. White saw the patient some time before the final admission, and he, like the rest of us, was puzzled but decided that she had heart disease of undetermined cause, or perhaps she belonged to the small group of cases that Dr Mallory may have trouble in deciding about too.

#### CLINICAL DIAGNOSES

Myocarditis of unknown etiology?  
Pulmonary embolism

#### DR SPRAGUE'S DIAGNOSES

Cardiac disease of unknown etiology (hypertensive?)  
Embolism to bifurcation of aorta  
Terminal pulmonary embolism

#### ANATOMICAL DIAGNOSES

Hypertrophy and dilatation of heart, generalized  
Coronary arteriosclerosis with occlusion, descending branch of right coronary artery  
Infarct of right ventricle  
Mural thrombi of right auricle and right ventricle  
Pulmonary emboli, multiple, with infarction  
Amputation of legs

#### PATHOLOGICAL DISCUSSION

DR MALLORY: There is a comment in the record by Dr White three years ago suggesting the probability of idiopathic myocarditis of the type described by Levy\*. I think, as in so many of these clinically difficult cases, the problem remains difficult after autopsy. I can only tell you what we found. The heart was very diffusely enlarged, in both right and left ventricles. We were particularly impressed by the enlargement in the right ventricle. There were thrombi present in the right auricle and numerous thrombi overlying the endocardium in the right ventricle. There were some gross foci of scarring in the right ventricle. The large coronary branches were relatively free from atheroma, but looking over the heart a second time we demonstrated an occlusion of one of the terminal branches of the right coronary artery. Microscopical sections from the right ventricle showed an area of infarction, underlying the thrombus. Sections of the left ventricle revealed only a spotty fibrosis, with nothing to suggest infarction. The aorta showed a rather minimal degree of arteriosclerosis. We found absolutely nothing in the left side of the heart to provide a focus for systemic embolism. Of course, that embolism occurred four years previously. The endocardium of the left ventricle was a little thick. It is possible that there was thrombosis at one time, most of which broke off, and the fibrous healing of the remainder showed only as a thickened endocardium. The patient had numerous pulmonary infarcts for which there were two sources — the right auricle and the right ventricle — so I do not believe we have to assume that she had further trouble in the remainder of the iliac veins. The amputated legs showed complete thrombotic occlusion of the popliteal vessels. About a month before death she had a rather definite episode of gnawing, substernal pain, and the infarct in the right ventricle was histologically compatible with that duration. I think those two episodes can be put together — first cardiac infarction and then pulmonary embolism secondary to the intracardiac thrombosis. We have no etiologic explanation for the diffuse hypertrophy of the heart. As Dr Sprague suggests, it may have been hypertensive heart disease, although the hypertension was not very convincing in the later period of life, or as Dr White suggested, it was at some earlier period an idiopathic enlargement of the heart, which we can no longer prove.

DR SPRAGUE: Was there a separate embolus in each popliteal artery, or was it a thrombotic process?

DR MALLORY: The emboli were apparently separate, we do not know.

## FALL MEETING OF THE COUNCIL

THE Council of the Massachusetts Medical Society met on October 6. The meeting was conspicuous by the absence of the usual reports of councilors' deaths since the previous meeting, and by the presentation of a new gavel to the President. The acceptance was in verse, graceful, gracious and witty.

President James C. McCann of Massachusetts Medical Service reported on the organization and current activities of Blue Shield, after which the main business of the Council was taken up—the consideration of reports of committees. The meeting was in many spots wholesomely controversial, as befits a democratic procedure, but was kept on a level course by skillful handling and wise decisions from the chair.

The report of the Committee on Cancer was referred back to the Committee for the development of a method of voluntary registration of cancer cases that might be acceptable to the Council.

The Committee on Tax-Supported Medical Care had recommended the approval of certain policies and procedures for a medical care program of the Office of Veterans' Services, subject to renegotiation. It was pointed out by a councilor that this program called for day rates to be paid to physicians from 7 a.m. to 11 p.m. and night rates not until after 11 p.m. The apparent endorsement of a sixteen-hour day for physicians by an agency of a Government that otherwise recognizes a forty-hour week seemed to verge on inconsistency. The report was ordered tabled until after the program had been published in the *Journal*.

The Committee on Veterans' Affairs offered a resolution protesting against the policy of the Veterans Administration—previously condemned in a letter and editorial in the *Journal* on July 22, 1948—in advising veterans that they may attend any medical school in Europe at the expense of the Government. This report was approved, and the resolution adopted by the Council.

The Council in considering the usual long report of the Committee on Public Relations approved a public-health exhibit, disapproved a student loan fund, approved a state-wide health meeting and tabled the endorsement of an ascending scale of membership dues. It approved and referred to the Committee on Education the matter of granting an annual award to a fourth-year student in each of the three medical schools of the state.

The report of the Committee on Public Health concerned the prevention of sexual psychopathology and the inclusion of this subject in the postgraduate medical education program, the Heart Demonstration in Newton and Framingham, active immunization against tetanus, the endorsement of Diabetes Week and the problem of geriatrics. The report was accepted, and its recommendations approved by the Council.

All other committee reports were approved. These included the reports of the Committee on Membership, the Advisory Committee to the Red Cross Blood Bank, the Committee on Arrange-

ments, the Subcommittee on Mental Health and the Committee on Benevolence. The last-named committee recommended that the by-laws be amended to provide for a standing committee on benevolence that would co-operate with the Massachusetts Medical Benevolent Society, with an annual budget.

Certain matters that had been referred to the Executive Committee by the Council at the annual meeting in May were considered. The Committee on Postgraduate Assembly was made a subcommittee of the Committee on Postgraduate Medical Education. The Council voted that the Society sponsor the art exhibit of the Massachusetts Physicians Art Association. A Section on Pathology and Physiology was recommended. A committee was approved that would confer with the directors of the newly formed Bay State Medical Rehabilitation Clinic, to consider in what manner the Society might best assist in the establishment of the clinic.

Under suspension of rules the Council endorsed in principle, on motion of Dr W A R Chapin, of Hampden, certain resolutions on specialty boards that have been presented to the House of Delegates of the American Medical Association by the delegates of the Medical Society of the State of New York.

### RUTLAND'S GOLDEN JUBILEE

THE Great and General Court of the Commonwealth of Massachusetts on June 5, 1895, approved a bill for the establishment of a "Massachusetts Hospital for Consumptives and Tubercular Patients." On September 24, 1898, a proclamation by Governor Roger Wolcott announced that the same "Massachusetts Hospital for Tuberculous Patients," the title somewhat modified, would open on or after October 1 of that year, on October 3 the first patient was admitted.

Thus there came into existence the first state sanatorium for tuberculous patients to be built in this country. The Trudeau Sanatorium at Saranac was already in operation, and Dr Vincent Y Bowditch had established his hospital in Sharon, Massachusetts in 1891, but these were both private institutions. With the opening of the sanatorium at Rutland a new marker was set in place beside

the road of progress in public health. As Dr Paul Dufault, its present superintendent has written, "What is considered obvious today was in the realm of bold thinking fifty years ago."

The sanatorium at Rutland, however, came near to missing its mark at the very beginning of its career, the original bill called for the establishment of a hospital for the terminal care of advanced cases of tuberculosis. It was owing to Dr Alfred Worcester, general practitioner extraordinary and a member of the original commission and board of trustees, that the idea was changed and the purpose of the establishment directed toward the treatment of patients in whom the prognosis might be considered as favorable.

The first superintendent of The Massachusetts Hospital for Tuberculous Patients, now the Rutland State Sanatorium, was Dr Walter J Marcle. The first visiting physicians were Dr Vincent Y Bowditch and Dr Herbert C Clapp. Treatment of the patients was conservative, for, as Dr Clapp wrote at the end of the first year

— in addition to constant and copious potations of the beautiful Rutland fresh air, *day and night*, and the other modern hygienic measures now recognized necessities for consumptives, medicines have been given in almost all cases, but use has been made only of those which are well known to our physicians generally.\*

Dr Clapp also disagreed with most authorities of the time, who believed that whisky, up to a pint a day, was beneficial to tuberculous patients.

The experiment at Rutland was followed with considerable interest outside Massachusetts. In 1905 an Ohio State Commission visited the institution, and delegations are recorded from Maryland, Indiana, Virginia, Alabama, Minnesota, New York, Nevada, New Mexico, Louisiana, Missouri, Iowa, California, New Hampshire, Maine and Vermont, as well as from Canada, England and Korea. Assistance from Rutland was sought in the organization of other state sanatoriums. In 1907 Dr Marcle went to the State Sanatorium of Minnesota, and in the same year Dr Bayard T Crane left to become the head of the Maryland State Sanatorium, and Dr Henry B Dunham to become an assistant at New Jersey's first institution of the kind.

\*Dufault, P. Fiftieth anniversary of Rutland State Sanatorium. *Massachusetts Health J.* 29:6, 1948.

As Kronick indicates in his paper published elsewhere in this issue of the *Journal*, at first only incipient cases of tuberculosis were accepted at Rutland, because they were considered to be reasonably curable. During the first twenty-five years of the institution's existence over 45 per cent of the applicants were rejected as having disease that was too advanced for treatment. The second twenty-five years have shown a great increase in advanced cases, and consequently in the average age of patients, to the point where, in 1947, far advanced cases made up 60.5 per cent of the sanatorium population.

The records at Rutland represent also, as Kronick shows, a catalogue of the progress that half a century has brought in the treatment of tuberculosis. Although whisky was frowned on from the beginning, overfeeding was at first the rule and the overstuffed patients were encouraged to take more exercise than is now permitted. As the bed rest was increased the calories were reduced, from a maximum of 5000 to an average of 2300 daily.

Pneumothorax was introduced in 1911, first with nitrogen, later with air, bronchoscopy and thoracoplasty came together in 1927, the first increasing and the second decreasing in use since that time, the first lobectomy was performed in 1940.

So the Rutland State Sanatorium, its golden jubilee over, continues to serve the people of the Commonwealth. Venerable so far as institutions of its kind are concerned, it has seen great changes in the vital statistics of the disease that it was built to treat. Its patients, like itself, have grown older, it is in the realm of possibility that coming generations will no longer need its services and that its destiny may some day be considered as fulfilled.

## THE CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ON October 25, 1923, the Case Records of the Massachusetts General Hospital became a special feature of the *Journal*. When these reports, previously published independently by the Hospital, were about to be discontinued for lack of financial support,<sup>1</sup> the *Boston Medical and Surgical Journal* undertook to incorporate them into its pages. In

announcing this fact the *Journal* emphasized the value of the exercises in presenting "correct and modern methods of treatment."<sup>2</sup> Throughout the years in which they have been a regular part of the *Journal*, the Case Records have not only fulfilled the high standard promised but also proved one of its most interesting and popular features. Moreover, clinicopathological conferences, of which the "Cabot Case Records" were the prototype, have become "one of the most characteristic features of American medical teaching."<sup>3</sup>

The history of the Case Records actually goes back to 1895, when Dr. Richard C. Cabot first began using "in private quiz exercises at my own office, some of the printed case histories which had been used by Dr. Frederick C. Shattuck on the examinations in clinical medicine."<sup>4</sup> The first published cases appeared in 1911, and the exercises were continued in the *Journal* under the editorial supervision of Dr. Cabot until July 4, 1935, when Case 21271 was published with Dr. Tracy B. Mallory as editor.<sup>4</sup> The reports have since then been published under Dr. Mallory's expert guidance, with the assistance of Dr. Benjamin Castleman and Miss Edith E. Parris.

Among the many anniversaries celebrated this fall, none is more deserving of hearty congratulations than the twenty-fifth in their present form of the Case Records of the Massachusetts General Hospital. The high standard of these exercises has never been relaxed, and their editors have merited the praise and thanks of all who find the reports a source of inspiration. Having established the form of the clinicopathological conference, the Case Records have remained foremost in interest and value and have continued to justify the high regard in which such conferences are universally held. "the clinicopathological conference is the wonder of many of our foreign visitors, who see in it a candor and fearlessness altogether to the credit of American medicine."<sup>5</sup>

## RED CROSS CONFERENCE

CERTAIN principles of warfare as it should be waged when war becomes inevitable were reaffirmed at the seventeenth International Red Cross conference held in Sweden in August of this year. One new treaty that would afford wartime protection to civilians and revisions of others were proposed and approved, and many new resolutions were passed. The proposed new treaty and revisions will be presented for adoption to a diplomatic conference of nations to be held in Switzerland at a later date.

One of the resolutions that was passed called upon nations to outlaw the atomic bomb, a righteous exhortation and one that will fall upon receptive ears if it seems to the best interest of those nations concerned to heed it. That this situation is not altogether impossible of attainment may be adduced from the absence of gas warfare in the open hostilities so recently suspended. People who live in glass houses do not throw stones, and the enlightened nations of the world may still be considered as genuinely opposed to indiscriminate slaughter.

The main change proposed in the Geneva treaty for the relief of the wounded and sick on the battlefield had to do with the status of captured military medical personnel. Instead of being returned home at once when captured as is supposed to be their disposition under the present convention, medical officers may be detained by the captor in sufficient numbers to care for the captured sick and wounded of their own army.

In view of the unparalleled ferocity and barbarity with which certain belligerents waged the recent war, the present efforts of the Red Cross may seem like a totally unrealistic excursion into the realms of wishful thinking. Such is not the case. Only by frequent reaffirmation of the basic principles of acceptable human conduct can the distinction between right and wrong remain clearcut. Any country that disregards the generally accepted standards of civilized behavior must be made aware that its actions are intolerable to the majority of nations.

## MASSACHUSETTS MEDICAL SOCIETY

## DEATHS

ALLEN — William H. Allen, M.D. of Mansfield died on September 19. He was in his eighty-first year. Dr. Allen received his degree from Harvard Medical School in 1894.

His widow survives.

DUNPHY — Henry A. Dunphy, M.D. of Palmer, died on June 11. He was in his sixty-seventh year.

Dr. Dunphy received his degree from Baltimore Medical College in 1908. He was a member of the staff of Mercy Hospital in Springfield and was associate medical examiner for the Palmer District of Hampden County. He was a fellow of the American Medical Association.

His widow, four sons, two daughters and four brothers survive.

FAUNCE — Calvin B. Faunce, M.D. of Boston, died on September 22. He was in his sixty-seventh year.

Dr. Faunce received his degree from University of Maryland School of Medicine in 1904. He was formerly assistant professor of otology at Harvard Medical School and was chief of staff of the Eye, Ear, Nose and Throat Division, Faulkner Hospital and a member of the staffs of the Massachusetts Eye and Ear Infirmary, Massachusetts General Hospital, Children's Hospital and Brookline Contagious Hospital. He was a member of the American Laryngological, Rhinological and Otolological Society, American Otolological Society, Incorporated and New England Otolological and Laryngological Society and a fellow of the American College of Surgeons and American Medical Association.

His widow, a son and two daughters survive.

KLEIN — George Klein, M.D. of Norwood, died on June 18. He was in his fifty-eighth year.

Dr. Klein received his degree from Tufts College Medical School in 1914. He was a member of the staffs of Norwood and Faulkner hospitals and was a member of the American Society of Anesthetists, Inc., and a fellow of the American Medical Association.

His widow, a son, three brothers and two sisters survive.

LUBINSKY — Henry Lubinsky, M.D. of Fall River, died on May 25. He was in his forty-sixth year.

Dr. Lubinsky received his degree from Tufts College Medical School in 1927. He was chief of pediatrics at Fall River General and St. Anne's hospitals and a member of the staff of Union Hospital. He was a fellow of the American Medical Association.

His widow, a daughter, two brothers and six sisters survive.

## BLUE CROSS—BLUE SHIELD

## PREMATURE INFANTS

Effective immediately Blue Shield will interpret care rendered to a premature infant weighing  $4\frac{1}{2}$  pounds or less as being other than routine. This means that payment for such care will be made to any participating physicians beginning on the day of delivery.

## MISCELLANY

## DR. HOWARD M. CLUTE MEMORIAL

A movement has been put on foot and a committee formed to erect a memorial that will pay tribute to Dr. Howard M. Clute's long and unselfish services to the New England Baptist Hospital and the community. It has been proposed that this memorial take the form of an auditorium in connection with the Hospital to meet the educational needs of nurses, of doctors and of the community.

## "IN TIME OF PEACE —"

Demands on the nation's health resources in the event of war would far exceed the supply, according to the medical advisory committee of the National Security Resources Board. The committee has therefore recommended that the Board include administration of an over-all national health policy in planning for wartime organization of the Government.

## NOTICES

### ANNOUNCEMENT

Dr Benjamin F. Sieve announces the removal of his office to 314 Commonwealth Avenue, Boston.

### NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff will be held in the Classroom of the Nurses' Residence, on Thursday, November 4, at 7:15 p.m., with Dr Augusta Hayck as chairman. Dr William L. Fleming will speak on the subject, "Modern Concept of Syphilology".

### MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

The fall meeting of the Massachusetts Public Health Association will be held on the opening day (November 8) of the convention of the American Public Health Association, in the Salle Moderne of the Hotel Statler at 2:30 p.m. A program entitled "A Progress Report of Activities of the Special Legislative Commission on Public Health for the Commonwealth of Massachusetts" will be presided over by Dr Vlado A. Getting, with introductory remarks by Senator Richard H. Lee. The reports of the technical committees will be presented by the chairmen, as follows: Local Health Administration, Dr Hugh R. Leavell; Preventable and Chronic Diseases, Dr Conrad Wesselhoef; Sanitation, Dr John H. Cauley; and Maternal and Child Health, Dr Warren R. Sisson. The discussion will be led by Dr Henry D. Chadwick, Professor Curtis M. Hilliard and Dr L. Jackson Smith.

The meeting will be open to all interested persons.

### NEW ENGLAND HEART ASSOCIATION

A meeting of the New England Heart Association will be held at the Peter Bent Brigham Hospital, Boston, on Monday, November 8, at 8:15 p.m., Dr Samuel A. Levine, presiding.

#### PROGRAM

Dicumarol in the Prevention of Thromboembolic Phenomena in Congestive Failure. Drs Clement A. Finch and W. Proctor Harvey.

Uncomplicated Pulmonic Stenosis. Drs Harper Hellemis, Milton Elkin and Lewis Dexter.

The Enlarged Pulmonary Artery. Drs James E. Dow, Raymond Healey, James Whittenberger and Eugene C. Eppinger.

Diodrast Studies in Congenital Heart Disease. Drs Martin Wittenborg and Edward B. D. Neuhauser.

Grafting of Blood Vessels. Dr Robert E. Gross.

Further Notes on Auscultation of the Heart. Drs Samuel A. Levine and W. Proctor Harvey.

Interested physicians and medical students are cordially invited to attend.

Future meetings are planned as follows (all meetings on Mondays at 8:15 p.m.): December 6, 1948, at the Massachusetts General Hospital, Boston, Dr Paul D. White, chairman; January 10, 1949, at the Boston City Hospital, Dr Laurence B. Ellis, chairman; February 7, 1949, at the Massachusetts Memorial Hospitals, Boston, Dr Robert W. Wilkins, chairman; and March 28, 1949, at the Beth Israel

Hospital, Boston, Dr Herrman Blumgart, chairman. At its annual meeting, on a date to be specified, the Jackson Lecture will be delivered.

Members who wish to present papers and are staff members of hospitals in which no meeting has been scheduled can probably be fitted into the program of one of the other hospitals and should get in touch with the secretary of the New England Heart Association as soon as possible.

### FREE MONOGRAPHS ON CANCER

The American Cancer Society has prepared a brochure series of illustrated monographs aimed at providing physicians with up-to-date information for the early recognition of cancer. Available free to all physicians, these articles are written by cancer specialists highly competent in their fields, and will appear at two-month intervals.

Physicians who have received notice of this series from the American Cancer Society (Massachusetts Division) are asked to return their cards at their earliest convenience. Any Massachusetts physician who wishes to be placed on the mailing list and who has not received a notice, may write to the American Cancer Society, 462 Boylston Street, Boston 16, or call Copley 7-2650.

### SOCIETY MEETINGS AND CONFERENCES

#### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, NOVEMBER 4

##### THURSDAY NOVEMBER 4

\*7:15 p.m. Monthly Clinical Conference and Staff Meeting. Nurses' Residence. New England Hospital for Women and Children.

##### FRIDAY NOVEMBER 5

\*9:00 a.m. 12:00 p.m. Combined Medical and Surgical Staff Rounds. Peter Bent Brigham Hospital.  
\*12:00 p.m. X-Ray Conference. Margaret Jewett Hall. Mt. Auburn Hospital. Cambridge.

##### MONDAY NOVEMBER 8

\*12:15-1:15 p.m. Clinicopathological Conference. Main Amphitheater. Peter Bent Brigham Hospital.  
\*2:30 p.m. Massachusetts Public Health Association. Salle Moderne. Hotel Statler.  
\*8:15 p.m. New England Heart Association. Peter Bent Brigham Hospital.

##### TUESDAY NOVEMBER 9

\*12:15-1:15 p.m. Clinicoröntgenological Conference. Peter Bent Brigham Hospital.  
\*1:30-2:30 p.m. Pediatric Rounds. Burnham Memorial Hospital for Children. Massachusetts General Hospital.

##### WEDNESDAY NOVEMBER 10

\*11:00 a.m. 12:00 p.m. Medical Rounds. Amphitheater. Children's Hospital.  
\*12:00 p.m. 1:00 p.m. Clinicopathological Conference (Children's Hospital). Amphitheater. Peter Bent Brigham Hospital.  
\*2:00-3:00 p.m. Combined Clinic by the Medical, Surgical and Orthopedic Services. Amphitheater. Children's Hospital.

\*Open to the medical profession.

## ACUTE RENAL INSUFFICIENCY DUE TO LOWER-NEPHRON NEPHROSIS\*

MAURICE B. STRAUSS, M.D.†

FRAMINGHAM, MASSACHUSETTS

### PATHOLOGY

ACUTE renal insufficiency due to the disorder now known as lower-nephron nephrosis<sup>1</sup> or hemoglobinuric nephrosis<sup>2</sup> occurs in association with a large variety of conditions, including intravascular hemolysis associated with transfusion reactions,<sup>3-7</sup> blackwater fever,<sup>8</sup> quinine sensitivity<sup>9</sup> and transurethral prostatectomy,<sup>10, 11</sup> as well as in the crush syndrome,<sup>12-23</sup> nontraumatic muscle ischemia,<sup>24</sup> electrical injury to muscle,<sup>25</sup> heat stroke,<sup>26</sup> uretero-placental damage,<sup>27, 28</sup> after abortion,<sup>29</sup> alkalosis from excessive vomiting,<sup>30</sup> thermal burns,<sup>31, 32</sup> sulfonamide sensitivity<sup>33-36</sup> and from various poisons of diverse origin,<sup>1</sup> including the most common offender, carbon tetrachloride.<sup>37-45</sup>

The purpose of this communication is to present certain data pertinent to this syndrome and to suggest that treatment based on the pathological physiology of this type of renal failure offers considerable promise.

### CLINICAL ASPECTS

Irrespective of the antecedent condition associated with this syndrome the clinical features and the histologic pathology appear similar if not identical. With or without an initial period of shock, dependent on the precipitating cause, patients often develop nausea, vomiting, weakness, malaise, sometimes pain in the abdomen or back and, abruptly or insidiously, oliguria or anuria. The magnitude and severity of the general manifestations frequently so divert attention from what at the moment seems a minor matter that it is often difficult to determine just when the urine volume declined or became nil. After renal shutdown, edema generally develops (the magnitude depending on the nature of the treatment), the blood pressure rises, the nonprotein nitrogen steadily mounts, acidosis becomes chemically apparent, and death generally ensues from pulmonary edema or, in certain cases, from potassium intoxication.

The histologic pathology as noted by Lucké<sup>1</sup> and Mallory<sup>2</sup> and others is essentially as follows: eighteen to twenty-four hours after onset there is lipid vacuolization of the ascending limbs of Henle's loop. Precipitation of pigment casts in the distal convoluted and collecting tubules is generally noted thirty-six to seventy-two hours after onset. This pigment usually gives a positive reaction to benzidine, but does not contain stainable iron. Moderate dilatation of the proximal and sometimes of the distal convoluted tubules follows the pigment precipitation. Sometimes on the third day, and regularly by the fourth and fifth days, necrosis and regeneration of the epithelium in the ascending portions of Henle's loop and in the distal convoluted tubules become evident, and simultaneously lymphocytes appear between the tubules and about the vessels. From the fifth day on rupture of the tubules becomes frequent. There is no significant change in the glomerular capillaries. The capsular space and the lumen of the proximal convoluted tubules may contain a variable amount of amorphous and granular debris. Edema of the interstitial spaces of the kidney is frequently seen. This may well be related to the generalized edema induced by the administration of large quantities of parenteral fluids. The basement membrane of the tubules is usually intact. Available evidence suggests that the re-epithelization of the tubules, albeit imperfect, is completed generally within two weeks of onset.

Although emphasis in the literature has been placed on the anuria and renal pathology it is to be noted that liver damage also occurs.<sup>2, 3, 8, 9, 12, 20, 21, 26, 27, 33, 36</sup> Bywaters,<sup>49</sup> one of the original describers of the crush syndrome, has recently reported central or midzonal liver-cell necrosis following crush or other skeletal injury in 42 patients, the majority of whom died in uremia. In carbon tetrachloride poisoning liver damage is so constant that many physicians are surprised that renal failure often overshadows the hepatic injury.<sup>45</sup>

### SURVIVAL TIME AND CAUSE OF DEATH IN FATAL CASES

Lucké<sup>1</sup> has determined the survival time in 100 fatal cases of lower-nephron nephrosis. Ninety-five per cent of the patients succumbed within fourteen days, 86 per cent within ten days, and 48 per cent within six days. No deaths occurred after twenty days. Burwell, Kinney and Finch<sup>7</sup> reviewed 89 cases of oliguria following intravascular hemolysis. Fifty-one of the 55 patients in the fatal cases succumbed within the first two weeks — 26 within six days. The other 4 deaths occurred on the six-

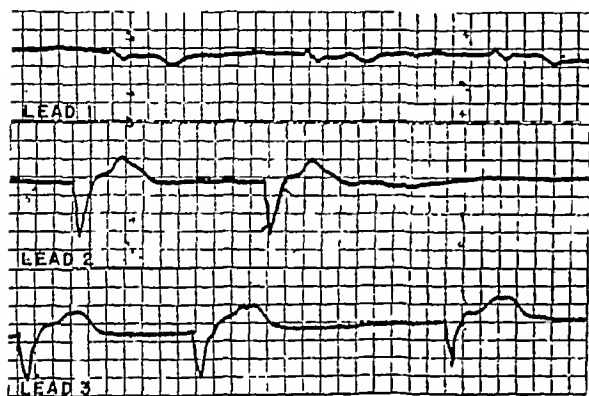

FIGURE 1 *Electrocardiogram in Case 4 Shortly before Death*

teenth, seventeenth, eighteenth and twentieth days respectively.

That factors probably unrelated to the kidney may be of very considerable importance in many fatal cases is suggested by the large number of deaths (50 per cent) within the first six days. It appears highly unlikely that renal insufficiency per se would ever lead to death within such a brief period. There is no doubt that the underlying or precipitating condition is frequently the major cause of a fatal outcome, and it is also probable that in some cases the hepatic damage is significant. Massive generalized edema, as well as pulmonary edema, is a common finding at autopsy,<sup>1, 2, 50</sup> the pulmonary form often being the immediate cause of death. Until the last year all the patients in the fatal cases of hemoglobinuric nephrosis observed by me died with, and probably from, pulmonary edema.

The level of the blood nonprotein nitrogen seems to bear little correlation with the outcome. Lower values are more often encountered in fatal cases than in patients who ultimately recover. The blood nonprotein nitrogen of 2 recently studied patients who recovered reached 225 and 255 mg per 100 cc respectively whereas in 5 fatal cases the highest values were 115, 154, 182, 195 and 240 mg per 100

cc. In Lucké's<sup>1</sup> series the nonprotein nitrogen levels in 10 fatal cases were, in ascending order of magnitude, 109, 114, 150, 175, 188, 218, 225, 240 and 260 mg per 100 cc.

Several investigators<sup>1, 19, 23, 29</sup> have commented on the possible role of potassium intoxication in the fatal outcome through alterations of cardiac function. In 1 case (Case 4) typical electrocardiographic changes of hyperpotassemia preceded death (Fig 1). Winkler and his associates<sup>51</sup> have shown that if potassium salts are injected intravenously in dogs rapidly enough to raise the serum potassium level a reproducible series of electrocardiographic changes occurs, terminating in death from ventricular flutter, fibrillation or arrest when the level reaches 14 to 16 milliequiv per liter. At a serum potassium level of 5 to 8 milliequiv, the T waves become tall and peaked, at 8 to 9 milliequiv, the ST interval is depressed, and the T waves become diphasic. The P waves decrease in size and disappear at 9 to 11 milliequiv per liter, and at the same level intraventricular block occurs. Orally administered potassium salts fail to elevate the serum potassium level significantly in the dog with normal renal function.<sup>52</sup> However, if renal insufficiency has been produced, the same sequence of electrocardiographic changes follows the oral administration of potassium when the serum levels rise.<sup>52</sup> In dogs experimentally rendered anuric, similar electrocardiographic changes follow the increasing concentration of potassium in the blood that occurs as a result of endogenous protein catabolism.<sup>53</sup> There is thus considerable evidence that potassium intoxication is important in certain cases of lower-nephron nephrosis.

### ONSET OF DIURESIS IN SURVIVING PATIENTS

In 34 cases of hemoglobinuric nephrosis reported by Burwell, Kinney and Finch<sup>7</sup> in which the patients recovered diuresis began from the second to the twelfth day in 32 and began on the fourteenth and sixteenth days in 2 cases. In the 4 cases reported by Humphrey and Avery Jones<sup>49</sup> diuresis began on the thirteenth to the fifteenth day after the onset of anuria. The patients in Kugel's<sup>50</sup> cases began passing appreciable amounts of urine on the ninth and tenth days. The 2 patients who recovered in the cases presented below had spontaneous diureses on the tenth and fifteenth days of anuria. Many other cases of spontaneous diuresis in the second and third weeks after the onset of anuria may be found. The evidence, therefore, is suggestive that in lower-nephron nephrosis with anuria or oliguria the damage is not always irreversible, and regeneration of the tubular epithelium is possible and may be anticipated in the majority of cases within the first two or three weeks if the patient can be kept alive long enough for healing to occur.

Once recovery from the acute episode has taken place, complete physiologic restitution may be expected to occur over a period of several months<sup>7, 29, 50</sup>

#### MAXIMUM SURVIVAL PERIOD WITHOUT RENAL FUNCTION

It is currently believed that after complete renal shutdown man can survive at most two or three weeks. This belief has developed during recent years when the parenteral administration of fluids became a routine procedure for a great variety of conditions. In an endeavor to ascertain how long patients with complete anuria survived prior to the days of parenteral fluids the older literature was studied<sup>51-59</sup>. It was not altogether surprising to find that many patients were reported as surviving from three to four weeks, 1 for five weeks, 2 for six weeks, and 3 for seven weeks. Since the possibility exists that certain of these observations were in error it is worth calling attention to 5 of these reported cases in particular in which there appears to be little probability that any urine was formed during the period of observation. In the first of these removal of the right kidney was performed for carcinoma of the kidney twenty-seven and a half days before death<sup>55</sup>. Autopsy revealed the congenital absence of the left kidney. In the second case the patient survived removal of the right kidney for hydronephrosis for twenty-three days before post-mortem examination disclosed the congenital absence of the left kidney<sup>53</sup>. A third patient who died after twenty-five days of anuria was shown at autopsy to have both ureters completely obstructed by cancer<sup>55</sup>. The left kidney was represented by a thin-walled cyst, and the right by a hydronephrotic sac containing a pint of urine. The fourth patient had had chills and fever together with anuria for three days at the age of thirty-two and for eleven days a year later, with recovery associated with the passage of pus-laden urine<sup>56</sup>. At the age of thirty-four, after twenty-two and a half days of anuria during which she was closely observed to make certain that there was no deception, she was operated upon. The left kidney was absent, and 500 cc of thick, foul-smelling pus was evacuated from the right kidney pelvis. Many stones were found in the calyces and one calculus completely occluded the right ureter. Recovery was uncomplicated. The fifth patient succumbed thirty days after the onset of complete anuria due to obstruction of both ureters by pelvic carcinomatosis<sup>57</sup>.

Animal experimentation has been somewhat misleading. It has frequently been observed that guinea pigs and rats die a few days after bilateral ureteral ligation<sup>59</sup> or after anuria has been produced by occlusion of both renal arteries for two hours<sup>60</sup>. The survival of rabbits<sup>61, 62</sup> and of dogs<sup>63-65</sup> is somewhat longer, whereas sheep and goats generally

do not succumb for two weeks<sup>59</sup>. Presumably, elephants might well survive for months. The increased ability of larger animals to survive without functioning kidneys may in part be ascribed to the fact that the rate of formation of metabolic waste products is a function of the rate of total body metabolism, which in turn is correlated with surface area. The amount of body water, however, in which these products may be distributed and thus diluted is almost a linear function of body weight. This penalty of small size has also been noted in infants and children, and has been commented upon by Gamble<sup>66</sup>.

#### THEORETIC CONSIDERATIONS IN TREATMENT

At this point it may be well to consider the course of events that may ensue in an otherwise healthy adult man weighing 70 kg who suddenly lost all function of both kidneys but who did not suffer from "toxic destruction" of body protein<sup>67</sup>. There would be a daily insensible loss of approximately 1000 cc of water by evaporation from the skin and lungs<sup>66</sup>. In the absence of actual sweating no appreciable amount of electrolyte would be lost. Gastric intolerance for food would probably appear and preclude nutrition by mouth, leading to the rapid exhaustion of the scanty body stores of carbohydrate. Approximately 70 gm of body protein would then be broken down daily<sup>68</sup> and the remaining caloric need supplied by the burning of about 200 gm of body fat. In the course of this catabolism of fat and protein, ketone acids, nitrogenous waste products, potassium, sulfate and phosphate would accumulate in the body. Preformed water and water of oxidation in the amount of 470 cc daily would be released, leaving an approximate daily deficit of 530 cc. The nitrogenous waste products would be distributed throughout the entire body water of approximately 50 liters and would rise steadily, as would the level of potassium in the body fluids. The accumulation of ketone acids as well as sulfate and phosphate anions would be followed by a reduction in the carbon dioxide content of the plasma. Rising plasma phosphate may be accompanied by a lowering of the calcium. However, the presence of acidosis should protect the patient from actual tetany. The daily negative water balance, increasing the osmotic pressure of the extracellular fluids, would lead to cellular dehydration. The duration of life under these circumstances is uncertain. It appears likely that the rise in serum potassium would lead to fatal cardiac changes before nitrogen retention or acidosis became threatening.

If isotonic electrolyte solution is given parenterally concentration of the extracellular electrolytes with secondary cellular dehydration will nevertheless occur by virtue of the evaporation of electrolyte-free water from the skin and lungs. If on the other hand, sufficient distilled water is admin-

istered to replace the water loss, concentration of the electrolytes in the body fluids should be kept reasonably constant. If, further, 100 gm of glucose was given daily, ketosis would be prevented and protein breakdown would be reduced by almost half as demonstrated by Butler et al<sup>68</sup> and by Winkler and his co-workers<sup>69</sup> in their studies of fasting man. This would mean that the nitrogenous waste products, potassium, sulfate and phosphate released by protein catabolism would accumulate at only half the rate that they would have accumulated if glucose had not been received. How rapidly should the nonprotein nitrogen rise in this hypothetical person who is now receiving 100 gm of glucose a day and whose insensible loss of water is taken care of? The metabolism of 37.5 gm of protein daily will lead to the formation of 6000 mg of nonprotein nitrogen, which will be distributed throughout the entire body water (amounting roughly to 50 liters), and therefore the blood nonprotein nitrogen should rise at a daily rate of 12 mg per 100 cc. By similar calculations it is possible to determine that the daily rise in serum potassium, sulfate and phosphate will be respectively 0.324, 1.86 and 1.66 milliequiv per liter, on the assumption that the potassium will be distributed in a volume equivalent to the total body water,<sup>63, 70</sup> and that the sulfate and phosphate are distributed only in the extracellular water. Actually since some portion of the phosphate will be deposited in bone or other tissues the rise of serum phosphate will be much slower.

Such data as are available suggest that these rates of increase for nonprotein nitrogen, potassium and sulfate are correct,<sup>29</sup> although the rise in potassium may be slower than expected, possibly owing to an increase in the nonionized fraction of intracellular K-proteinate.<sup>71</sup> Serum sodium levels show no marked deviation from the normal range. Observed serum chloride and bicarbonate values have been lower than those anticipated from the rise in sulfate and phosphate. In a case in which sufficient data were obtained to allow calculation of the electrolyte balance,<sup>29</sup> the sum of the anions— $\text{Cl}' + \text{HCO}' + \text{PO}'' + \text{SO}'' + \text{protein}$ —was consistently lower than that of the cations— $\text{Na} + \text{K} + \text{Ca}$ . No explanation for this discrepancy was apparent.

#### TREATMENT

The treatments that have been suggested in the management of acute anuria or oliguria are many and diverse. They include spinal anesthesia, splanchnic block, diathermy to the kidney region, x-ray irradiation of the kidneys, acetyl-beta-methylcholine injections, irrigation of the renal pelvis, decapsulation or capsulotomy of the kidney, transfusion of compatible blood or plasma, or both, intravenous sodium sulfate, intravenous hypertonic fluids, including glucose and saline solution, massive

intravenous administration of saline or lactate solutions, peritoneal lavage and the use of an artificial kidney. Recently enthusiasm for capsulotomy has been noted.<sup>72, 73</sup> J. T. Peters<sup>74</sup> has advanced the theory that anuria is due to edema of the kidney, which produces an increase in the intrarenal pressure, effectively preventing the flow of urine. The fact remains that in patients who recover diuresis starts at the height of fluid retention and thus at a time when the edema of the kidney may be anticipated to be at its greatest. Furthermore, there is no evidence for the existence of edema of the kidney at the onset when the anuria first occurs. The subject of capsulotomy has recently been reviewed,<sup>75</sup> and the evidence in its favor found wanting. It is to be noted that most of the successes reported in the literature indicate that the operation was performed between the eighth and the tenth day, which is the period in which spontaneous diuresis most often occurs. It is of particular interest that in Talbot's<sup>76</sup> case, in which operation was performed on only one kidney, but catheters placed in both ureters, diuresis began at precisely the same time on each side.

There is no doubt that peritoneal lavage can successfully remove large amounts of nitrogen from the body.<sup>66, 77-82</sup> However, the difficulties involved in maintaining water balance and the frequent development of peritonitis have caused some workers<sup>81</sup> to discard this method of tiding the patient over the period needed for tubular regeneration. The artificial kidneys developed by Kolff<sup>83</sup> and Alwall<sup>61, 62, 84</sup> offer considerable promise for the future. However, evidence available at present indicates that the number of patients with lower-nephron nephrosis who will require such management may be materially reduced by the more widespread use of the conservative therapy of restricted fluids and glucose administration. Although Wakeman et al<sup>85</sup> advocated such a procedure a decade and a half ago, Kugel<sup>86</sup> was unable to find any case of acute toxic nephrosis so treated. He treated 2 patients by rigidly limiting their fluids and obtained uneventful recovery. Since then Muirhead and his associates<sup>81</sup> and Burnett<sup>86</sup> have recommended similar treatment.

The therapeutic regime employed in the treatment of all patients with anuria or oliguria from lower-nephron nephrosis at the Cushing Veterans Administration Hospital has been divided into three phases.

If shock or dehydration is present in the initial phase of this syndrome, whole blood, plasma or saline solution is employed to combat these phenomena.

The second phase of treatment begins when it is observed that the urine volume is markedly diminished or anuria has occurred. Then 750 cc of 15 per cent glucose in distilled water is given

by vein daily, care being taken to run this in slowly, with every precaution to avoid thrombosis of veins. If necessary a vein is cut down upon. Nothing is given by mouth since vomiting appears to be increased by the oral administration of food or liquid. If there is significant vomiting the amount is carefully measured and that much physiologic saline solution is added to the daily infusion of dextrose in water. During the second week of treatment great fortitude is required because of the insistent demands that the patient be drowned with large volumes of intravenous fluid. This must be resisted. If acidosis becomes clinically manifest (as well as being evident on laboratory examination) a liter of one-sixth molar sodium lactate is given, the extracellular fluid volume being thus expanded as the price for combating acidosis.\* Electrocardiograms are made at least every other day for the observance of changes indicative of an excess of potassium. It is my hope at present that it may be possible to combat this if it occurs, by the insertion of a modified Miller-Abbott tube into the small intestine and the perfusion through it into the proximal jejunum of a slightly hypertonic, potassium-free electrolyte and dextrose solution, which is withdrawn from the distal ileum, where its potassium content should be in equilibrium with the blood plasma. With such a procedure Maluf<sup>88</sup> has been able to achieve blood urea clearances of 32 cc per minute. Any loss of sodium is then replaced intravenously with either potassium-free Ringer lactate or one-sixth molar sodium lactate solution.

When the stage of diuresis appears in the second or third week the third phase of treatment is employed, which consists in administration of a volume of water sufficient to make up for the total urine volume in addition to 1000 cc for insensible loss as well as any other losses, together with the amount of sodium chloride found in the preceding day's urine. Frequently, during the phase of diuresis, moderate to severe anemia is noted. This is treated by the transfusion of carefully matched blood. If the patient's anuria has been due to a hemolytic transfusion reaction the greatest of care is exercised in the administration of blood although with proper precautions this is a safe procedure. In the state of diuresis the kidney is producing an only slightly modified glomerular filtrate as urine, which may show only a twofold or threefold concentration of nitrogen and very little ability to conserve sodium chloride. Accordingly, salt

depletion must be avoided. Furthermore, at this time when the urine volume may be well in excess of 2 or 3 liters daily, the danger of drowning the patient has become remote.

### CASE REPORTS

In the following cases the lower-nephron nephrosis was treated by intravenous administration of large volumes of saline solution. Death from pulmonary edema ensued.

**CASE 1 (CVAH 578)** A 40-year-old man, 2 days after drinking with a friend (Case 2) on November 28, suffered nausea and vomiting, followed by a steadily falling urinary output. Approximately 2 liters of 5 per cent dextrose in physiologic saline solution was administered by vein daily. The urine specific gravity was 1.010, with a + test for albumin, and there were a few red and white blood cells in the sediment. The blood nonprotein nitrogen was 72 mg per 100 cc. on December 2 and 115 mg on December 7. The carbon dioxide capacity was 15.3 milliequiv per liter on December 7.

The urinary output during the last 24 hours was 2000 cc.

Autopsy revealed central necrosis of the liver, lower-nephron nephrosis, two 0.6-cm ulcerations in the duodenum, pulmonary edema and bilateral hydrothorax, with 300 cc. of fluid in the left and 400 cc. in the right pleural cavity. The left lung weighed 1300 gm, and the right 1250 gm. Microscopical examination showed the alveoli to be filled with edema fluid. Examination of the viscera was negative for poisons of the heavy-metal group.

**CASE 2 (CVAH 596)** A 36-year-old man, 2 days after drinking with a friend (Case 1) on November 28, noticed nausea and vomiting together with tremulousness and hallucinations. From December 1 to 4, inclusive, 9000 cc. of 5 per cent dextrose in physiologic saline solution was given intravenously in the face of a falling urinary output. Periorbital ecchymoses appeared spontaneously on December 3 and spread over the chest on December 6. Edema of the face and extremities was noted on December 4 and of the lungs on December 5. The urine specific gravity was 1.015, with an acid reaction and a +++ test for albumin and a few red and white blood cells in the sediment. The blood nonprotein nitrogen was 157, 162 and 195 mg per 100 cc. on December 4, 5 and 6. The plasma chloride was 87, and the carbon dioxide capacity 8.5 milliequiv per liter on the day of death (December 6). The blood prothrombin was 30 per cent of normal, the Lee-White coagulation time 19 minutes, and the bleeding time 2 minutes. No fluids were given on December 5. Death occurred 6 hours after intravenous infusion of 1000 cc. of physiologic saline solution in addition to 500 cc. of one-sixth molar sodium lactate.

No autopsy was performed.

In the following case of lower-nephron nephrosis following an extensive brain hemorrhage, pulmonary edema was controlled by rigid restriction of fluids.

**CASE 3 (CVAH, 4601)** A 29-year-old man was subjected to a second craniotomy and exploration of the third ventricle on January 16. Two transfusions of blood were given. During the next 3 days the temperature increased to 106°F, and a period of hypotension lasting 18 hours occurred. Consciousness was never regained after operation. From January 20 to 23 inclusive the patient received 4000 cc. of 5 per cent dextrose in distilled water and 4000 cc. of 5 per cent dextrose in physiologic saline solution intravenously. From operation until January 20 he was incontinent of an unknown amount of urine. Thereafter he was completely anuric. On January 23 both lungs were filled with moist rales. During the next 7 days he received 750 cc. of 15 per cent dextrose in distilled water by vein daily, with the gradual complete clearing of all signs of pulmonary edema. The blood nonprotein nitrogen rose from 96 mg per 100 cc. on January 21 to 182 mg on January 28, the plasma chloride fell to 81.2, and the carbon dioxide capacity to 10.4 milliequiv per liter. Death occurred on January 30 (1 week after the restriction of fluids).

\*If any degree of base dilution has occurred from the excessive intake of 5 per cent sodium bicarbonate solution may be employed. Not infrequently when first seen these patients have already received large quantities of water by mouth or fluids of low salt content parenterally and as a result may exhibit significant hypotonicity of expanded body fluids. Such salt depletion even in the presence of edema may be greatly corrected by the intravenous administration of 3 to 5 per cent sodium chloride with or without bicarbonate. It should be emphasized that in these patients the tonicity of the blood cannot be estimated with accuracy from the serum chloride and bicarbonate.

Autopsy revealed a normal degree of hydration throughout the body. The left lung weighed 450, and the right, 500 gm. There was no evidence of pulmonary edema. Lower-nephron nephrosis was present. A large operative defect in the right frontal lobe of the brain was filled with a blood clot, which extended across the midline to obliterate the basal ganglions on the left and to involve the corpus callosum and insula. The blood clot measured approximately 130 cc. Numerous cysts lined with a single layer of endothelial cells occupied

ination was negative except for hypertension, the blood pressure being 160/110. The lungs were clear. The urine was neutral, with a specific gravity of 1.012, a ++ test for albumin and red and white blood cells in the sediment. The blood nonprotein nitrogen was 185 mg per 100 cc, rising to 240 mg, and the serum chloride 85.5 milliequiv per liter, falling to 80.3 milliequiv, the carbon dioxide capacity was 13.8 milliequiv per liter, falling to 8.5 milliequiv before death on June 11. Treatment was limited to the administration of 1800 cc of 15 per cent dextrose in distilled water intravenously during 40 hours in the hospital. Three electrocardiograms were taken. On June 9 the P waves were low, the QRS complexes widened and slurred, and the ST intervals depressed. The QT interval was 0.36 second. On June 10 the P waves were absent, the T waves were tall and wide, and the QT interval was 0.52 second. Shortly before death on June 11, there was an idioventricular rhythm with a rate of 32, the QRS complexes measured 0.20 second, and the QT interval was 0.92 second (Fig. 1).

Autopsy showed lower-nephron nephrosis and central necrosis of the liver. The pleural cavities each contained 250 cc of fluid. The left lung weighed 660 gm, and the right 600 gm. Microscopical examination disclosed atelectasis

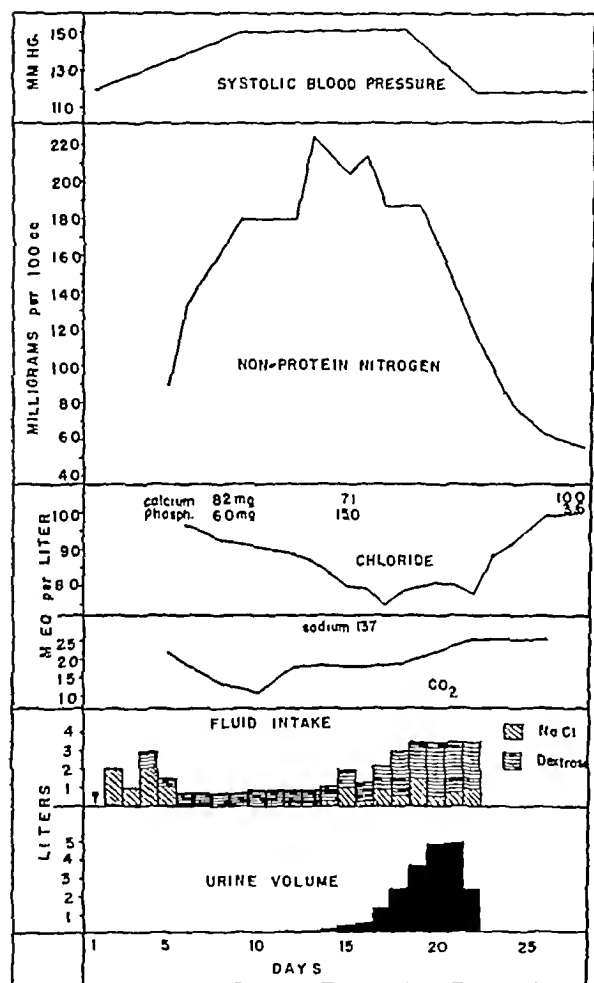

FIGURE 2 Essential Data in Case 6

the right thalamus, hypothalamus, midbrain and pons. Blood was present over both hemispheres and the base of the brain.

In the following case the lower-nephron nephrosis was self-treated by fluid restriction. Death with the electrocardiographic changes of hyperkalemia occurred. There was no pulmonary edema.

**CASE 4 (CVAH 3857)** A 52-year-old man had partaken freely of whisky on May 30. He denied the ingestion of any unusual beverages or foods. On June 2 he felt weak, complained of pain in his back and noted a diminished urinary output. Anorexia, nausea and some vomiting began on June 4. He took no food whatsoever and restricted his fluids to less than 1000 cc daily. The urinary output diminished steadily. When, on June 9, it was less than 2 oz, the patient became alarmed and sought hospitalization. Physical exam-

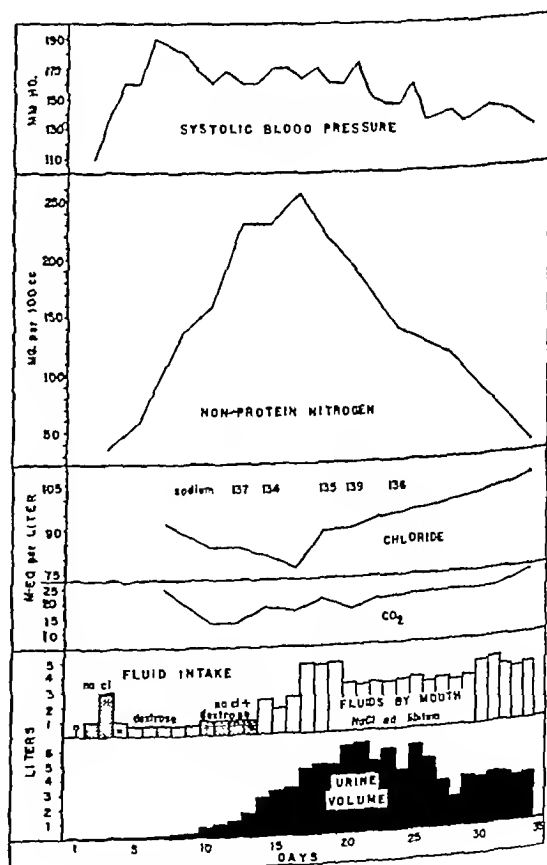

FIGURE 3 Essential Data in Case 7

of the left lower lobe and a small infarct in the right lower lobe but no significant pulmonary edema.

The following case of lower-nephron nephrosis was complicated by severe hypertension and nitrogen retention. The urinary output was normal.

**CASE 5 (CVAH 6331)** A 35-year-old man developed anorexia, nausea and vomiting several days after drinking to excess on October 12, followed by pain in the lumbar region

on October 16 and two convulsive seizures on October 17, after which he was admitted to the hospital.

Two years before admission he had begun to have convulsive seizures occurring at intervals of several months. Eight months after the first seizure his skull was fractured when struck by an airplane propeller. He was unconscious for an unknown period and was hospitalized for a fortnight.

On admission to this hospital the patient was agitated, confused and hallucinated. Numerous ecchymoses were observed over his body. The blood pressure was 220/120. The ocular fundi were normal. All deep tendon reflexes were hyperactive. The urine volume averaged 2000 cc daily. The specific gravity varied from 1.006 to 1.010, a + test for albumin was constantly observed, and red and white blood cells were present in the sediment on all examinations. The spinal fluid was under normal pressure but showed over 5000 red cells per cubic millimeter. On October 22 the blood nonprotein nitrogen was 175 mg per 100 cc., falling to 154 mg 2 days later, when the serum chloride was 73.3 milliequiv and the carbon dioxide capacity 14.7 milliequiv per liter. The blood pressure during his 8 days in the hospital varied from 176/98 to 220/140. A convulsion on October 23 was followed by increased clouding of the sensorium. Several small flame hemorrhages developed in the left retina, and the arteries were observed to be contracted. An electrocardiogram on October 22 was normal. The QRS complexes measured 0.07 second. Two days later the P waves were wider, the PR interval was 0.21 second, the QRS complexes widened and slurred (0.11 second), and the T waves tall and peaked. Death occurred on October 25.

Autopsy revealed central necrosis of the liver and lower-nephron nephrosis, with no evidence of antecedent renal disease. The lungs were free of edema, the left weighing 250 gm and the right 200 gm. There was a depressed fracture of the left parietal region of the skull with an area of brain necrosis 3 cm deep beneath it.

The following cases of lower-nephron nephrosis were treated by fluid restriction and dextrose administration.

**CASE 6 (C\A H 865)** A 28-year-old man, while drinking in a hotel bar on March 9, became nauseated and began to vomit. He continued to vomit during the 5 succeeding days and passed no urine after March 10. From March 11 to 14 inclusive he received intravenously 6000 cc of 5 per cent dextrose in physiologic saline solution and 1500 cc of 5 per cent dextrose in distilled water. On admission to the Medical Service on March 14 the blood nonprotein nitrogen was 90 mg per 100 cc, and the carbon dioxide capacity 22 milliequiv per liter. At this time edema of the face and extremities was present. For the next 2 weeks the patient received nothing by mouth, with the rapid subsidence of excessive vomiting, so that only 100 to 200 cc. was regurgitated daily. Two hundred gm of dextrose was administered by vein daily, dissolved in 750 cc of distilled water with an additional amount equal to the preceding day's loss in vomitus. With the onset of diuresis he received an additional amount of physiologic saline solution approximately equivalent to the preceding day's urinary chloride output. (The frequent thrombosis of veins that occurred with the concentrated dextrose has since caused the use of any solution stronger than 15 per cent to be abandoned, in addition the evidence cited above<sup>1</sup> indicates that 100 gm of dextrose is almost as effective in reducing protein catabolism as 200 gm.) The essential data obtained in this patient are shown in Figure 2. Recovery was uneventful. Urine passed after the onset of diuresis was of a fixed specific gravity at 1.010 and contained albumin and red and white blood cells.

**CASE 7 (C\A H 6969)** A 40-year-old man was drinking on October 18. On the following day he had severe vomiting and weakness of his right arm and leg of a peripheral neuritic type, possibly associated with the fact that he had been lying on the floor for some hours in a comatose state. During the day an unknown amount of urine was passed, the specific gravity of which was 1.010. The sediment contained albumin and red and white blood cells. Subsequently, he was anuric. During the first 2 days of anuria he received 4000 cc. of 5 per cent dextrose in saline solution and 1000 cc. of 5 per cent dextrose in distilled water on the 3rd day. At this time, when first seen, he had moderate generalized edema. For the

next 5 days he received 750 cc. of 15 per cent dextrose in distilled water by vein daily. No thrombosis occurred. With the onset of diuresis on the 9th day he was given 1000 cc of physiologic saline solution containing 100 gm of dextrose daily for 4 days, with the subsequent increase in his generalized edema and the appearance of moist rales throughout both lungs. On the night of the fourth day he had a generalized convulsion in which he fractured his left humerus. The serum calcium at this time was 9.3 mg per 100 cc. After this episode he appeared much improved and was able to take fluid and food by mouth. Although his intake rose to almost 5 liters, his diuresis kept pace with this. The pulmonary and generalized edema subsided, the blood nonprotein nitrogen fell, the serum chloride and carbon dioxide capacity rose, and he made an uneventful recovery. The essential data are shown in Figure 3. Nitrogen clearance was estimated after the onset of diuresis from the 24-hour output of nonprotein nitrogen in the urine and the blood nonprotein nitrogen. From 1.25 cc per minute on the 10th day of illness it rose steadily to 27.6 cc. 4 weeks later. A week after this the standard urea clearance determined in the usual fashion was 70 per cent of normal.

### SUMMARY AND CONCLUSIONS

The precipitating factors, clinical and chemical aspects and pathologic histology of lower-nephron nephrosis are reviewed.

Evidence is presented suggesting that neither nitrogen retention nor acidosis is responsible for the usual fatal outcome.

Fatal cases of lower-nephron nephrosis often exhibit generalized and pulmonary edema at autopsy, the pulmonary edema frequently being the immediate cause of death.

In the absence of pulmonary edema there is evidence that potassium intoxication may lead to a fatal outcome.

Available data indicate that man, unlike small animals, may survive without renal function for four or more weeks, if excessive quantities of fluids are not administered parenterally.

Histologic and clinical evidence indicates that the tubular lesion is often reparable, with spontaneous diuresis to be expected within three weeks if the patient can be kept alive this long.

A review of the many treatments proposed for this condition fails to reveal evidence that any of them speeds the appearance of spontaneous diuresis.

A regime is outlined consisting essentially in the replacement of water loss and the furnishing of 100 gm of dextrose daily, which it is believed may, in many cases, permit the patient to survive long enough to have spontaneous recovery.

Seven cases illustrating various phases of this syndrome and its treatment are reported.

## DICUMAROL THERAPY IN CONGESTIVE HEART FAILURE\*

J. H. WISHART, M.D.,† AND CARLETON B. CHAPMAN, M.D.‡

MINNEAPOLIS, MINNESOTA

AMONG the more serious threats to the life of the decompensated cardiac patient are thrombosis and embolism, and some means of combating these phenomena are a very pressing need in cardiovascular therapeutics. Recent work with anticoagulant agents<sup>1, 2</sup> in postoperative patients, in cases of myocardial infarction and in cases of thrombophlebitis suggests that the use of dicumarol offers a safe and effective method of preventing such accidents. To test the effectiveness of this drug, all patients admitted to the Veterans Administration Hospital, Minneapolis, because of cardiac decompensation have been treated with dicumarol since October, 1946. The present report is a preliminary evaluation of the therapy as carried out up to August, 1947.

Although a clear description of hemorrhagic pulmonary infarcts was given by Laennec,<sup>3</sup> it was Virchow<sup>4</sup> who first proposed the view that these lesions were actually due to embolism of branches of the pulmonary artery and who suggested that stasis of the pulmonary circulation was a factor of some pathogenic importance. Experimental support for Virchow's views was supplied by Zahn,<sup>5</sup> who found that sterile mercury emboli, injected into the jugular vein, failed to produce hemorrhagic pulmonary infarcts in rabbits unless the thorax of the experimental animal was tightly bound within two days of the introduction of the embolus. Karsner and Ash<sup>6</sup> reported that obstruction of a branch of the pulmonary artery caused some circulatory changes in the lung tissue supplied by that branch but produced a hemorrhagic infarct only if stasis was effected by simultaneous ligation of the vein from the area.

From these earlier concepts grew the view, now generally accepted, that congestive heart failure predisposes to the development of thrombi in the veins or in the heart itself. These thrombi in time may give rise to infarcts, particularly in the lung, but also in other vital organs such as the brain and kidneys. It is of interest that although Laennec had no adequate concept of the pathogenesis of hemorrhagic infarcts of the lungs, both the illustrative cases he presented in his original description of the lesion were cases of severe congestive heart failure. In recent years a number of surveys

have shown conclusively that pulmonary infarcts occur extremely frequently with congestive heart failure and possibly more frequently with this condition than with any other single disease. Hampton and Castleman<sup>7</sup> reported a series of 370 cases of pulmonary embolism and infarction at autopsy. One hundred and eleven were cardiac cases, and of these, 90 per cent showed infarcts of the lungs. Of the noncardiac medical cases, 62 per cent showed infarcts of the lung, whereas in only 58 per cent of the postoperative cases were pulmonary infarcts found. Hines and Hunt<sup>8</sup> observed that 81 (34.6 per cent) of a series of 234 cardiac cases at autopsy showed gross pulmonary infarcts, although this lesion had been diagnosed clinically in only 2

TABLE 1 Incidence of Pulmonary Infarcts in Series of Kinsey and White<sup>10</sup>

TYPE OF CASE	TOTAL CASES	CASES OF PULMONARY INFARCT
Autopsy performed	45 (24.4%)	18 (40%)
Death but no autopsy	30 (16.3%)	8 (27%)
Survival of patient	107 (59.3%)	14 (13%)
<b>Totals</b>	<b>184</b>	<b>40 (22%)</b>

\*Grades II and III only

of the 81 cases. Greenstein<sup>9</sup> reported pulmonary emboli in 50 per cent of 32 cardiac cases at autopsy. Kinsey and White<sup>10</sup> reviewed 200 cases of congestive heart failure to ascertain the cause of the fever often seen in this disease. They described three grades of cardiac failure: left ventricular failure alone, moderate right ventricular failure (enlarged liver with slight to moderate dependent edema), and marked right ventricular failure with anasarca. Their Grades II and III conform almost exactly with the cases making up the present series for which reason their statistics have been recomputed leaving out their Grade I (left ventricular failure alone). Table 1, constructed from their data, shows the incidence of pulmonary infarcts in the autopsied the dead but not autopsied and the surviving members of the series. In a series such as theirs, and our own, the true incidence of pulmonary infarction probably lies somewhere between the minimum (clinical) figure of 13 per cent and the maximum (autopsy) figure of 40 per cent. That many infarcts of the lungs and of the other organs such as the kidney and spleen are never suspected clinically cannot be denied, yet one cannot accept the incidence of such lesions at autopsy as the true incidence in all cases of congestive heart failure, since not all persons with congestive failure die

No hemorrhagic complications developed in any of the cases although it was often necessary to suspend dicumarol therapy because of excessive depression of the prothrombin concentration

Vitamin K (30 mg intravenously, three or four times daily) was occasionally used to counteract excessive dicumarol effect, but this measure was rarely necessary

The mortality in the series was 32.8 per cent (20 deaths), and autopsies were done in 12 cases

### RESULTS

Probably the most significant finding in this survey is that there were no deaths definitely attributable to classic pulmonary embolism, and only 1

dence, has been taken to mean probable renal infarction

On the basis of clinical data, definite pulmonary infarcts developed in 2 patients on dicumarol therapy. There is evidence, however, that the dicumarol effect was inadequate before and during the time the embolic phenomena appeared. One of the patients developed thrombophlebitis at a time when dicumarol dosage was adequate, but some days later, when pulmonary infarction occurred, the prothrombin concentration ranged between 30 and 35 per cent. Although these levels are borderline, this case is included in our list of dicumarol failures. The other patient was put on dicumarol therapy because he had previously de-

TABLE 3 *Infarcts Found at Autopsy*

PATIENT	TYPE OF HEART DISEASE	LOCATION OF THROMBI	LOCATION OF INFARCT	OCCURRENCE OF INFARCTION
C A	Isolated myocarditis	Left ventricle	Right kidney	Before dicumarol treatment
C V	Acute myocardial infarct	Left ventricle	Lower lobes of lungs	Before and during dicumarol treatment
C M	Arteriosclerotic	Left auricle	Right kidney and spleen	Before dicumarol treatment
C L	Hypertensive and arteriosclerotic	Left auricle	Lower lobes of lungs	After dicumarol treatment
B G	Rheumatic	Left auricle	Lower lobes of lungs	After dicumarol treatment
J H	Hypertensive and arteriosclerotic	Femoral vein	Lower lobes of lungs	Before and after dicumarol treatment

death might conceivably have been due to such a condition. The patient was an eighty-two-year-old man who had severe arteriosclerotic heart disease and whose electrocardiogram showed left bundle-branch block. His decline was actually gradual but death occurred unexpectedly, and since there was no autopsy one cannot rule out massive pulmonary embolism as the immediate cause of death. In none of the remaining 19 cases was death sudden enough or the terminal symptoms suggestive enough to permit the diagnosis of fatal pulmonary embolism. No such embolus was found in any of the 12 autopsied cases although small emboli were present in several.

The clinical diagnosis of nonfatal embolism and infarction in the lungs is notoriously difficult and in many cases is frankly impossible. Under the best of conditions many infarcts remain silent and undiagnosed. In the present work symptoms and signs were carefully scrutinized for evidence of infarction. In addition, elevations in temperature, pulse rate, white-cell count and sedimentation rate, x-ray films of the chest and urinary-sediment, serum-bilirubin and urinary-urobilinogen determination were specifically studied. Unexplained elevations in temperature, pulse or sedimentation rate probably do not constitute sufficient evidence for the diagnosis of infarction unless accompanied by other evidence such as appropriate symptoms and signs, the visualization of pulmonary lesions by x-ray study or elevation in serum bilirubin or urine urobilinogen. On the other hand, unexplained hematuria, alone or in combination with other evi-

veloped pulmonary infarction. Since there was a rather marked initial drop in the prothrombin concentration, dicumarol was discontinued and was not started again for nine days. During the three days preceding the appearance of fresh infarcts of the lung, the prothrombin concentration ranged between 60 and 70 per cent, and it seems likely that the complication would have been avoided if the dicumarol dosage had been adequate. The case was therefore not included in the group of dicumarol failures. Two patients had transient, microscopic hematuria (2 or 3 red cells per high-power field in a single specimen) while on dicumarol therapy, but in 1 case the infarct, if present, occurred before adequate reduction in the prothrombin concentration had been obtained. In the other case dicumarol therapy was adequate, and the case was accepted as one of dicumarol failure.

At autopsy infarcts (other than myocardial) were present in 6 out of 12 cases. From the ages of the lesions as judged morphologically, it was possible to determine with reasonable certainty whether the infarcts had occurred before, during or after dicumarol therapy. In 5 cases infarcts had developed either before dicumarol had been given or after it had been withdrawn. In the remaining case pulmonary infarction had apparently occurred in spite of adequate doses of dicumarol. The patient, who was suffering from massive myocardial infarction, developed large mural thrombi and multiple pulmonary infarcts but was so ill that the complication did not become clinically

while under observation. In fact, death may occur partly as a result of multiple embolic phenomena so that the incidence at autopsy, as compared with the incidence in a series of this type, is probably unduly high. We believe that the figure 22 per cent is as close as one can come at present to the true incidence of pulmonary infarcts in patients with congestive heart failure, not all of whom die and none of whom are treated with anticoagulants. The true incidence is almost certainly no lower, and may well be somewhat higher.

### MATERIAL

To arrive at a preliminary evaluation of the therapy the records of all patients treated were reviewed. Patients with dyspnea and basal rales as the only indication of decompensation were excluded. Minimum requirements for inclusion in the series comprised such signs as hydrothorax, enlarged tender liver, peripheral edema and elevation of the venous pressure. All except a few pa-

TABLE 2 *Types of Heart Disease*

Rheumatic	16	26
Hypertensive and arteriosclerotic	11	18
Hypertensive	7	12
Myocarditis etiology unknown	2	3
Syphilitic	1	—
Congenital defect with bacterial endocarditis	1	—

tients had peripheral edema, and many had anasarca. The total number of cases exhibiting definite congestive failure was 61. On the basis of the criteria of Kinsey and White 20 of our cases fell into Group II and 41 into Group III.

The ages of the patients in the series varied from twenty-two to eighty-four years, about two thirds being in the group from fifty to fifty-nine years. Ten patients were less than fifty, and 11 were over sixty years of age.

The average stay in the hospital was fifty-three days, the range being from nine to two hundred and ten days. Thirty of the 61 patients were in the hospital from two to six weeks, and 30 for more than six weeks. Only 1 patient was in the hospital for less than two weeks.

The types of heart disease represented in the series are shown in Table 2. There were 7 patients (12 per cent) with acute myocardial infarction and congestive failure, all 7 are included in the arteriosclerotic or hypertensive and arteriosclerotic categories. In 19 cases (31 per cent) auricular fibrillation was present, and there were definite signs of mitral stenosis in 11 (18 per cent). All 3 of these conditions probably predispose, independently of cardiac decompensation, to thrombosis and embolism. In spite of this fact no attempt was made

to rule out patients with any of the 3 conditions. Congestive failure was the only basis for selection.

### METHOD

Before a patient was given dicumarol, a careful search was made for contraindications to the use of the drug. According to Allen et al.,<sup>1</sup> these include renal insufficiency, blood dyscrasias that in themselves cause increased tendency to bleed, hepatic disease associated with a decrease in prothrombin concentration, ulcerative lesions of various sorts and operations on the brain or spinal cord after which bleeding might be fatal. The same authors regard subacute bacterial endocarditis as a probable contraindication. If no contraindications were present, a sample of blood for determination of the prothrombin time was withdrawn, and the initial dose (usually 200 mg) of dicumarol was given orally. In a few cases, small doses of heparin were given intramuscularly in addition to the dicumarol for the first twenty-four or forty-eight hours. Once the administration of dicumarol was begun, the prothrombin time was determined daily, and the dosage of the drug was adjusted accordingly. The aim was to keep the prothrombin concentration below 30 per cent and above 10 per cent, as suggested by Allen and his co-workers.<sup>1</sup> The average initial prothrombin concentration, before dicumarol was started, was 62 per cent of normal, and in 1 case it was only 17 per cent. We interpret this to be further evidence that liver function may be significantly impaired in congestive heart failure. Cotlove and Vorzimer<sup>11</sup> studied the prothrombin time in 20 patients with congestive heart failure and concluded that the disorder does not per se influence the prothrombin time. Their data do not include control prothrombin times and for this reason are difficult to interpret. The present figures provide strong evidence that congestive heart failure may depress the prothrombin concentration (and increase prothrombin time) quite markedly.

The average number of days during which dicumarol was given was twenty-three, the range being from two to fifty-nine. The average duration of adequate dicumarol effect, as judged by the prothrombin time, was thirty-two days, with a range of four to one hundred and two. In most cases the drug was continued until the patient was ambulatory or until death supervened. The average total dose of dicumarol was 2255 mg, and the average daily dose was 105 mg. The latter figure is somewhat misleading in that it is calculated from the number of days on which dicumarol was actually given. Perhaps a more pertinent figure is the average dose per day of adequate dicumarol effect, which was 78 mg. This is in accord with the view that patients in cardiac failure require smaller doses of dicumarol than compensated persons do.<sup>11</sup>

## CLOSED-LOOP OBSTRUCTION OF THE ASCENDING COLON, WITH INCOMPLETE DESCENT OF THE CECUM, SIMULATING ACUTE CHOLECYSTITIS\*

EUGENE A. GASTON, M.D.,† and MAURICE E. COSTIN, M.D.‡

FRAMINGHAM, MASSACHUSETTS

**C**LINICAL findings and laboratory tests frequently fail to indicate accurately the pathologic status of the gall bladder in acute cholecystitis. Gangrene with incipient or actual perforation may exist with minimal physical signs and with normal or only slightly elevated temperature and blood counts. For these reasons and because of the ease and safety of cholecystectomy in the early stages of the disease, early operation is being advocated with increasing frequency.<sup>1-31</sup> The purpose of this communication is to present 2 cases in which acute, closed-loop obstruction of the ascending colon in combination with incomplete descent of the cecum was mistaken for acute cholecystitis, a diagnostic pitfall that may be avoided if both conditions are kept in mind when acute surgical problems involving the right upper quadrant of the abdomen are encountered.

### CASE REPORTS

**CASE 1** A 47-year-old woman was admitted to the hospital on January 7, 1941, complaining of abdominal pain of 5 hours' duration.

Two years before admission she began to complain of intermittent, dull, nagging pain in the right side of the abdomen, which was indefinitely located at the level of the umbilicus and in the right upper quadrant. She also noted flatulence and a feeling of distention following meals, which was relieved by belching. She had always been constipated, requiring a cathartic once or twice a week. Repeated questioning failed to elicit a history of change in bowel habits or abnormal stools. Three months before admission examination by her family physician revealed mild tenderness in the right middle portion of the abdomen. She was placed on a regimen that included milk of magnesia and mineral oil. Thereafter her bowels moved regularly and the abdominal pain disappeared, but gas and indigestion following food, particularly airy and fried food, persisted. She was instructed to take a fat-free diet, and 2 months later her weight had fallen from 150 pounds to 166 pounds. This was believed to be due to the low-calorie intake. A Graham test on December 18, 1940, showed no filling of the gall bladder.

About 2 weeks before admission abdominal pain recurred, at this time located in the right upper quadrant, nonradiating and considerably more severe than that during previous episodes. A bile-salt preparation prescribed at this time caused several watery stools a day but did not relieve the abdominal pain. Five hours before admission the patient was awakened by the sudden onset of excruciating pain in the right upper abdomen radiating to the right scapular region and associated with nausea and vomiting. When she was seen at home by the family physician the entire right side of the abdomen was found to be spastic and tender and she was immediately hospitalized.

Physical examination revealed a well developed, moderately obese woman who complained bitterly of pain in the right upper quadrant. The tongue was dry and furred. The heart was normal and the lungs were clear. The entire right side of the abdomen was tender and spastic, with the point

of maximum tenderness about 4 cm below the costal margin in the midclavicular line. Rebound tenderness was present throughout the abdomen and was referred to the right upper quadrant. No masses were felt. Pelvic and rectal examinations were noncontributory.

The temperature was 98°F, the pulse 90, and the respirations 20.

Each of two urine specimens showed no abnormalities. Examination of the blood disclosed a red-cell count of 4,530,000, with a hemoglobin of 91 per cent, and a white-cell count of 6700, with 61 per cent neutrophils. The icteric index was 9.

An initial diagnosis of acute cholecystitis and cholelithiasis was made, and operation was deferred until the fluid and electrolyte balance could be re-established. During the first 8 hours of hospitalization the abdominal tenderness progressively diminished, her general condition improved, and the white-cell count fell to 5400. At the end of this time she suddenly entered a state of peripheral vascular collapse, with rapid thready pulse and a blood pressure of 80/60. A poorly defined mass could then be felt in the right upper quadrant. Transfusion of whole blood was started at once, with rapid improvement. It was thought that the acutely inflamed gall bladder had perforated and as soon as her condition permitted, she was transferred to the operating room.

At operation the gall bladder was found to be normal. The cecum was incompletely descended and lay in the right upper quadrant. Five centimeters distal to the hepatic flexure was a small annular carcinoma, which completely obstructed the transverse colon. A huge retroperitoneal abscess was found in the right upper quadrant. Its lateral wall, consisting of parietal peritoneum overlaid the colon proximal to this lesion. This abscess was opened, and over a liter of bloody, foul-smelling pus was aspirated. A large area of gangrene was found on the posterior wall of the ascending colon near the hepatic flexure and in the center of this area was a perforation 2 cm in diameter. Since it was impossible to close the perforation satisfactorily, the right half of the colon was resected, the terminal ileum and transverse colon being exteriorized. During the operation the blood pressure fell to dangerously low levels in spite of the continuous administration of whole blood. After operation her condition continued progressively to deteriorate and she died 12 hours later. Permission for autopsy was refused.

**CASE 2** A 70-year-old woman was admitted to the hospital on March 28, 1948, with the chief complaint of abdominal pain.

Four years previously she had experienced an attack of fairly severe right-upper-quadrant pain which radiated to the right scapular region and which persisted for 24 hours. For 2 days thereafter she was mildly jaundiced but could not recall the color of stools or urine. Thereafter, she remained on a low-fat diet and, except for occasional bloating after meals, had no abdominal symptoms until the night before admission to the hospital. At that time she was awakened by the sudden onset of pain in the epigastrium radiating to the right upper quadrant. The pain was constant and associated with increasing tenderness. On the following morning the patient herself noted a mass in the right upper quadrant. There was no nausea or vomiting and she was emphatic in stating that her bowels moved daily and that there had been no change in bowel habits and no abnormal stools.

Physical examination revealed a well developed, well nourished woman in moderate distress. There was marked tenderness in the right upper quadrant of the abdomen associated with muscle spasm and some rebound tenderness. A firm tender mass about 6 cm in diameter, which descended with inspiration and appeared to be contiguous with the liver, was palpable below the right costal margin.

†Assistant professor of surgery, Boston University School of Medicine, Framingham Union Hospital.

‡Surgeon, Framingham Union Hospital.

manifest Further information on these 6 cases is given in Table 3

With the clinical and post-mortem evidence combined, it seems probable that embolic phenomena developed in 4 (6.5 per cent) of the 61 cases despite adequate dicumarol therapy If the comparison between our data and those of Kinsey and White<sup>10</sup> is valid, the difference in incidence of embolic phenomena in the two series (22 per cent in theirs, and 6.5 per cent in ours) is impressive This difference is statistically significant for samples of these sizes (sigma of the difference =  $\pm 4.4$ , observed difference = 15.5) It should be noted that we included embolic phenomena of all types in our reckoning, whereas Kinsey and White were concerned only with infarcts of the lungs If we exclude the case of renal infarction, the incidence of embolic phenomena in our series becomes 4.9 per cent

### DISCUSSION

That congestive heart failure predisposes to the development of thrombosis and embolic phenomena seems established For this reason the use of anticoagulants in the treatment of the disorder is theoretically fully justifiable In practice, dicumarol is not only effective as an anticoagulant but also safe if certain routine precautions are observed during its administration

To establish the efficacy of dicumarol therapy in congestive failure beyond question will require methodical treatment of many hundreds of cases with the drug Although the present series is not large enough to achieve this result, the fact that there were no deaths attributable with certainty to massive pulmonary embolism is highly suggestive, and the low incidence of embolic phenomena of lesser magnitude is only slightly less so

From our results we believe that dicumarol therapy is probably effective in protecting the patient with congestive heart failure from the danger of embolism and that controlled anticoagulant therapy may become as important in the treatment of the disorder as it already is in that of thrombophlebitis or of postoperative patients The protection it affords is apparently not absolute It seems likely that it retards or prevents the propagation of established thrombi, but it can hardly prevent the breaking off of unorganized projections

of a thrombus lying loose in a vessel or chamber of the heart Ideally, therefore, one should begin dicumarol therapy as early in the disease as possible and should continue it, in the absence of contraindications, as long as signs of cardiac decompensation remain

### SUMMARY AND CONCLUSIONS

Sixty-one patients with definite congestive heart failure were treated with dicumarol in an effort to decrease the incidence of embolic phenomena

Previously published reports indicate that in a group of cardiac patients comparable to our own, one may expect embolic phenomena in the form of infarcts of the lungs in at least 22 per cent In our series, the incidence of such lesions, during the period when dicumarol therapy was effective, was 6.5 per cent There were no deaths attributable with certainty to massive pulmonary embolism, and only 1 death that might conceivably have been due to such an accident

On the basis of these results, it is probable that dicumarol therapy gives protection from thrombosis and embolism to the cardiac patient when he needs it most when he is in congestive failure Further evaluation of the method is under way

titis In both the cases presented above the cecum had failed to descend and lay in the right upper quadrant of the abdomen

The differential diagnosis between acute, closed-loop colonic obstruction with incompletely descended cecum and acute cholecystitis depends primarily upon keeping the former condition in mind when one is dealing with lesions involving the right upper quadrant of the abdomen It is probable that in a majority of cases a carefully taken history will reveal significant changes in bowel habit preceding the onset of acute symptoms It should be emphasized, however, that such symptoms may be entirely absent as in the cases presented above Simple x-ray study of the abdomen, by demonstrating a distended loop of gas-filled colon in the right upper quadrant, may make the diagnosis obvious Such an examination was not done in Case 1 because of the sudden onset of serious peritonitis associated with shock In Case 2 an x-ray film of the abdomen failed to reveal the distention of the ascending colon and cecum because the closed loop was filled with fluid and contained relatively little gas The diagnosis in Case 1 was further confused by the positive Graham test done three weeks before admission Why the gall bladder failed to fill at this time is not clear

It is evident that the one procedure that will establish the diagnosis of colonic obstruction is x-ray examination with barium enema Because the combination of circumstances causing carcinoma of the colon to resemble acute cholecystitis is not commonly encountered, it is unlikely that routine barium enema is necessary when one is dealing with the clinical picture of acute cholecystitis Since acute obstruction of the colon due to cancer is probably invariably associated with the presence of occult blood in the stool, the guaiac test affords a simple screening method for determining when barium enema is indicated In the absence of obvious anal or rectal disease the presence of occult blood in the stool should serve as a warning that symptoms of acute cholecystitis may be of colonic origin

Since acute, closed-loop obstruction of the colon demands early surgery, just as acute cholecystitis does, the importance of emphasizing an accurate preoperative diagnosis might be questioned Emergency operations are often done at odd hours when operating-room personnel is limited An accurate preoperative diagnosis will point up the necessity for an adequate team before the abdomen is entered

Acute closed-loop obstruction of the ascending colon in the presence of an undescended cecum presents a problem in surgical management when the obstructing neoplasm is at or near the hepatic flexure Since the competent ileocecal valve prevents distention of the terminal ileum in the early stages, primary resection with end-to-end ileotransverse colostomy and proximal decompressing ileos-

tomy, followed by adequate antibiotic therapy, is the choice of many surgeons even in the absence of adequate preoperative preparation of the colon Such a choice proved adequate in Case 2 As an alternate method the ileum and transverse colon may be brought out on the abdominal wall to form an open ileotransverse colostomy, as advocated by Lahey Although such a procedure gives added protection against peritonitis, it has the disadvantage of subjecting the wound and surrounding skin to the digestive action of the ileal discharge If the wall of the cecum is so damaged that it will not withstand the manipulation necessary to a primary resection, a cecostomy for temporary decompression may be necessary although the resulting adhesions will complicate the subsequent resection Under these circumstances appendicostomy may be the operation of choice Such a procedure was rendered impossible in Case 2 by obliteration of the appendiceal lumen

### SUMMARY

Two cases are presented in which acute, closed-loop obstruction of the ascending colon in the presence of an incompletely descended cecum gave clinical pictures closely simulating that of acute cholecystitis

The differential diagnosis depends primarily on keeping the condition in mind when one is dealing with acute problems involving the right upper quadrant of the abdomen Simple x-ray examination of the abdomen may fail to demonstrate the obstructed loop The presence of occult blood in the stool should serve as an indication for barium enema x-ray studies when the clinical picture of acute cholecystitis is encountered

Operative therapy is briefly discussed The possibility of closed-loop obstruction of the colon should give added impetus to an aggressive attitude on the part of the surgeon confronted with the clinical picture of acute cholecystitis

The temperature was 98.6°F, the pulse 84, and the respirations 20. The blood pressure was 185/98.

Examination of the blood disclosed a red-cell count of 4,440,000, with a hemoglobin of 14.5 gm., and a white-cell count of 9850 with 84 per cent neutrophils, of which 2 per cent were stab forms. The urine was normal except for a rare pus cell in the sediment. The blood nonprotein nitrogen was 43 mg., and the total protein 6.3 gm. per 100 cc., with an albumin-globulin ratio of 1:4.1. The serum chloride was 491 mg. per 100 cc.

An x-ray film of the chest showed the lung fields to be clear, the heart and great vessels were normal. X-ray study of the abdomen revealed the presence of an ill defined soft-tissue mass in the right upper quadrant, the nature of which could not be determined. The lower pole of the right kidney was well seen and appeared normal. There were no opaque gall-bladder or urinary-tract calculi and no evidence of intestinal obstruction.

The initial diagnosis was acute cholecystitis, and, because of the evidence of peritoneal irritation, it was feared that perforation was imminent. Immediate surgery was therefore advised.

Operation was performed 3 hours after admission. The mass was found to be an incompletely descended cecum, which was greatly distended, but with its lower border above the level of the umbilicus. The colon was found to be obstructed at the hepatic flexure where there was a small, constricting carcinoma. The serosa of the colon was obviously invaded with cancer at this point, but there were no distinct metastases. The colon distal to the constricting carcinoma was of normal caliber. The ileocecal valve was competent, and the ileum was not distended. The very thin wall of the distended cecum appeared to be viable, and although there was a moderate quantity of cloudy peritoneal fluid in the right gutter, there was no evidence of perforation or peritonitis. Since the ileum proximal to the ileocecal valve and the transverse colon distal to the obstructing neoplasm were both of normal caliber, the entire right half of the colon and the distal 15 cm. of the ileum were resected with an end-to-end anastomosis of ileum to transverse colon. A catheter ileostomy for decompression was placed proximal to the suture line. Primary resection was considered the operation of choice because the incompletely descended cecum did not lend itself well to a cecostomy and, furthermore, cecostomy would have materially interfered with later resection of the neoplasm. An appendectomy was considered but was impossible because the lumen of the appendix was obliterated.

Postoperatively, convalescence was complicated by a period of obstruction of the small intestine, which was probably due to adhesions and which responded well to intubation. The wound healed by first intention, and the patient was discharged from the hospital on the 23rd postoperative day.

## DISCUSSION

Although much has been written on the treatment and prognosis of acute cholecystitis, remarkably little is to be found in the literature on the diagnosis of this condition. This point has been emphasized by Lawrence and Clute<sup>12</sup> in the discussion of 4 cases in which intrinsic diseases of the liver were responsible for the clinical picture usually associated with acute cholecystitis. In 3 of their cases tumors of the liver were found—2 metastatic, and 1 primary. The fourth patient had acute central necrosis of the liver due to carbon tetrachloride poisoning. The cases presented above indicate that lesions of the colon must also be considered in the differential diagnosis.

The diagnostic confusion between lesions of the colon and acute cholecystitis is dependent upon three factors: the site and type of obstruction, competence of the ileocecal valve, and incomplete descent of the cecum.

Colonic obstruction due to carcinoma usually progresses slowly over a period of several months and most commonly results from lesions located in the left half of the colon. In a series of 150 cases of carcinoma of the colon with complete obstruction reported by Gregg and Dixon<sup>13</sup> there were only 5 cases with the obstructing neoplasm in the cecum or ascending colon. In an additional 19 cases the obstruction was in the hepatic flexure or transverse colon. When obstruction of the colon is sudden and complete the resulting symptoms overshadow those of the chronic obstruction, which have usually been present for some time. Symptoms of chronic obstruction are due to the gradual stenosis of the lumen of the colon by the growing neoplasm. As pointed out by Mayo<sup>14, 15</sup> and Collier and Berry<sup>16</sup> this gradual stenosis may give rise to dyspepsia, with sour eructations and postprandial distress. These symptoms are often referred to the upper abdomen and may closely simulate those associated with gall-bladder disease.

Occasionally, symptoms of preceding chronic obstruction are completely absent, and the first indication of abdominal disease is the sudden, unheralded obstruction of the colon. This type of obstruction was present in 5 of 129 cases of carcinoma of the colon reported by Miller.<sup>17</sup>

Competence of the ileocecal valve is said to be present on routine barium-enema x-ray examination in about 10 per cent of cases.<sup>18</sup> If this valve is incompetent, acute obstruction of the colon results in progressive retrograde distention of the small intestine and the clinical picture usually associated with low intestinal obstruction. However, when the ileocecal valve is competent the distention resulting from acute obstruction of the colon is limited to the colon, and, because of its greater diameter and thinner wall, the distention is most marked in the cecum, regardless of the point at which the colon is obstructed. The degree of distention of the cecum under these circumstances frequently becomes so great that it causes areas of necrosis and eventual perforation.<sup>19-21</sup> The perforation of such a necrotic area was the cause of the sudden onset of shock in Case 1. In Case 2 the distended cecum formed an easily palpable, acutely tender mass, which was mistaken for a distended, inflamed gall bladder.

Rankin<sup>22</sup> has emphasized the fact that necrosis and perforation of the normally placed cecum due to closed-loop obstruction of the colon may give rise to a clinical picture resembling that of appendicitis. During the second trimester of intrauterine life the cecum normally descends from the right upper quadrant of the abdomen to the right lower quadrant. When this descent fails to take place and the cecum remains in the right upper quadrant the distention, necrosis and eventual perforation resulting from acute closed-loop obstruction may give rise to the clinical picture of acute cholecys-

Of interest was the development of signs of a pulmonary embolism immediately after full digitalization in Case 2. Such incidents suggest caution in the use of digitalis in patients who have already manifested minor embolic phenomena.

### SUMMARY

Two cases of fatal bacterial endocarditis developing after urethral dilatation are presented. In 1 patient, the history and physical signs gave ample evidence of rheumatic heart disease, in the other, such evidence was found at autopsy. It is pointed

out that chemotherapeutic or antibiotic prophylaxis should be utilized before and after manipulation in such cases.

**Bone.** Localization of the sarcoid lesions in bone has frequently been described, but the true incidence of such involvement is not known. The incidence of roentgenographically demonstrable involvement, however, has ranged between 15 and 25 per cent of cases in several series<sup>5, 35, 49, 131</sup>, in others it has been considerably lower,<sup>45, 132</sup> and only 1 case of such involvement has been reported from Australia.<sup>115</sup> The tendency of the lesions to appear at any time, to last for indefinite periods, to regress spontaneously and even to reappear at a later date<sup>44</sup> makes it necessary to follow cases for an adequate period by means of serial roentgenograms if such localizations are not to be missed. Furthermore, Schaumann<sup>132</sup> has shown that such localizations may occur, and probably often do without demonstrable roentgenographic or even gross pathologic manifestation, and a reliable estimate is therefore difficult to make even from the autopsied cases.

The radiologically visible bone lesions have a special predilection for the short bones of the hands and feet and, when demonstrable, are of considerable diagnostic significance. A similar appearance, however, has been described in leprosy.<sup>5, 134</sup> Lesions have also been demonstrated in the bones of the carpus and tarsus, in the long bones of the extremities and in the vertebrae.<sup>69, 125-127</sup> rarely they are seen throughout the skeleton, including the skull.<sup>40</sup> Histologic examination of such areas reveals diffuse involvement of the bone-marrow spaces, but only lesions that cause destruction of spongy bone or erosion of the compact bone are likely to be visible.<sup>5</sup>

The bone lesions, originally called "ostitis tuberculosa multiplex cystica (or cystoides)," have been described in great detail by Jüngling,<sup>135, 136</sup> Fleischner<sup>137</sup> and many others.<sup>5, 10, 35, 131, 138-140</sup> The roentgenographic appearance takes two main forms: a circumscribed type with characteristic cystoid areas of rarefaction, usually medullary, and with little or no surrounding reactive change, and a diffuse form in which multiple small areas of rarefaction produce a finely reticulated pattern extending over large portions of the bone, often associated with broadening of the shaft and thinning of the cortex.<sup>35</sup> Both types frequently coexist, however, and there may be transitions from one to the other.<sup>5</sup> External manifestations may be seen as fusiform swellings of the fingers or toes with occasional periarticular subcutaneous nodules or dystrophic nail changes. The swellings are usually symptomless though slight pain may occur in the early stages<sup>35</sup>; lack of pain is probably explained by the fact that periosteum and joints are rarely involved.<sup>5, 9</sup> Occasionally, diffuse, extensive bone destruction causes severe external deformity.

It is difficult to estimate the frequency with which external manifestations are associated with bone lesions. The latter certainly occur in the absence of such manifestations,<sup>5, 9</sup> and in at least one series all 6 cases with bone changes were discovered only by routine roentgenograms of the hands or feet.<sup>47</sup> In Reisner's<sup>25</sup> series, however, all but 1 of 9 cases with visible bone lesions showed external manifestations at the site of involvement. Such manifestations usually mean associated involvement of the skin and subcutaneous tissues of the hands and fingers, and it is of interest that Jüngling<sup>136</sup>

## BACTERIAL ENDOCARDITIS FOLLOWING URETHRAL MANIPULATION

### Report of Two Cases

JOHN K MENEELY, JR, M D \*

ALBANY, NEW YORK

REVIEWS in the older literature<sup>1-3</sup> and a recent article<sup>4</sup> have commented on the frequent occurrence of bacteremia following manipulation of the genitourinary tract. In one report<sup>3</sup> the complication of bacterial endocarditis in a case is noted, but a perusal of the literature since 1940 revealed no recently reported cases. To emphasize the occurrence of this complication and to stress the need for routine prophylaxis in persons with known valvular defects, the following cases of bacterial endocarditis, developing after urethral dilatation and terminating fatally, are presented.

**CASE 1** A 56-year-old man was admitted to the hospital on July 6, 1945, with the complaint of chills, fever and vomiting. A few hours previously, sounds had been passed for the relief of urethral strictures. Physical examination was negative, no cardiac murmurs were noted. A retention catheter was inserted, and 20,000 units of penicillin was given intramuscularly every 2 hours for ten doses. The temperature promptly fell to normal, and the patient was discharged 2 days after admission.

Two days later, the patient was readmitted to the hospital with a history of having developed severe chills and fever almost immediately after leaving the hospital. Physical examination revealed a soft, grating systolic murmur at the apex and a few posterior basal rales. He was catheterized, penicillin was given intramuscularly every 2 hours for 2 days in a dosage of 20,000 units and every 3 hours for 2 days in a dosage of 10,000 units. The temperature quickly fell, and the patient was discharged on the 4th hospital day.

Ten days later he was readmitted with complaints of continued chills, fever, malaise and severe headaches since arrival at home. At this time, no murmur was noted, but a gallop rhythm was present at the apex. No petechiae were observed, and the spleen was never felt. No organic defects were found on cystoscopy and retrograde pyelography on the 3rd hospital day, but colon bacilli were recovered from the bladder and both ureters. On the 9th hospital day several blood cultures were positive for colon bacilli, and purpuric spots appeared over the body. Intramuscular injections of penicillin (20,000 units every 3 hours) were begun at that time, but the patient became moribund and died on the 12th hospital day.

Autopsy disclosed old, inactive rheumatic inflammation of the mitral and aortic valves, with superimposed acute, ulcerative endocarditis of the left auricular endocardium and mitral valve. Post-mortem blood cultures from the heart were positive for colon bacilli. Focal embolic infarctions were seen in the kidney and spleen, and there were chronic, inflammatory changes in the urinary bladder and urethra.

\*Assistant in medicine, Albany Medical College clinical assistant in medicine Albany Hospital.

**CASE 2** A 56-year-old man was admitted to the hospital on November 7, 1947, with the complaint of shaking chills and fever for 1 week prior to admission. Three weeks before entry, he had undergone urethral dilatation for strictures, and a few hours later he had an episode of violent shaking chills and fever.

The past history revealed an attack of rheumatic fever as a child, necessitating bed rest for 11 months. Since that time, however, there had been no cardiac complaints.

Physical examination revealed a loud systolic and a harsh diastolic murmur at the aortic area, with much fainter replicas at the apex. No external stigmas of embolization were noted at that time, and the spleen was not felt. The remainder of the physical examination was noncontributory.

On the following day, numerous petechiae were noted on the abdominal wall, and several hemorrhagic bullae appeared on the toes of the right foot. Cultures of these bullae were positive for *Staphylococcus aureus* and were mannite and coagulase positive. Three cultures of blood drawn in the first 2 days were positive for the same organism. Intramuscular injection of penicillin (100,000 units every 4 hours) was begun. New bullae appeared on the hands, but the patient improved clinically. Seven days after entry, because of developing cardiac decompensation, the patient was digitalized a few hours later, the clinical picture of pulmonary embolism was evident. The patient rallied briefly at this point, but 2 days later became comatose and remained so until the time of death, 18 days after admission. Terminally, uremia was present. The penicillin was increased to 100,000 units every 2 hours on the 3rd hospital day, and to 200,000 units every 2 hours on the 5th day. All blood cultures taken after the initial three were negative. No autopsy was performed.

### DISCUSSION

The sequence of events in both cases and the similarity of the organism in the blood stream and urinary tract in 1 case make it evident that the endocarditis had a direct relation to the urethral manipulation. Although urethral dilatation is a common office procedure, such complications make it mandatory to consider the use of prophylactic agents in all persons subjected to these procedures. Persons with a clear history and definite signs of rheumatic heart disease must receive vigorous prophylaxis. The method of choice is not yet certain, but the use of penicillin, with or without sulfadiazine, for two days before and after manipulation, has been advised by Glaser et al<sup>4</sup> and Clark and his associates.<sup>5</sup>

Of interest was the development of signs of a pulmonary embolism immediately after full digitalization in Case 2. Such incidents suggest caution in the use of digitalis in patients who have already manifested minor embolic phenomena.

### SUMMARY

Two cases of fatal bacterial endocarditis developing after urethral dilatation are presented. In 1 patient, the history and physical signs gave ample evidence of rheumatic heart disease; in the other, such evidence was found at autopsy. It is pointed

out that chemotherapeutic or antibiotic prophylaxis should be utilized before and after manipulation in such cases.

## BACTERIAL ENDOCARDITIS FOLLOWING URETHRAL MANIPULATION

### Report of Two Cases

JOHN K. MENEELY, JR., M.D.\*

ALBANY, NEW YORK

REVIEWS in the older literature<sup>1-3</sup> and a recent article<sup>4</sup> have commented on the frequent occurrence of bacteremia following manipulation of the genitourinary tract. In one report<sup>3</sup> the complication of bacterial endocarditis in a case is noted, but a perusal of the literature since 1940 revealed no recently reported cases. To emphasize the occurrence of this complication and to stress the need for routine prophylaxis in persons with known valvular defects, the following cases of bacterial endocarditis, developing after urethral dilatation and terminating fatally, are presented.

**CASE 1** A 56-year-old man was admitted to the hospital on July 6, 1945, with the complaint of chills, fever and vomiting. A few hours previously, sounds had been passed for the relief of urethral strictures. Physical examination was negative, no cardiac murmurs were noted. A retention catheter was inserted, and 20,000 units of penicillin was given intramuscularly every 2 hours for ten doses. The temperature promptly fell to normal, and the patient was discharged 2 days after admission.

Two days later, the patient was readmitted to the hospital with a history of having developed severe chills and fever almost immediately after leaving the hospital. Physical examination revealed a soft, grating systolic murmur at the apex and a few posterior basal rales. He was catheterized, penicillin was given intramuscularly every 2 hours for 2 days in a dosage of 20,000 units and every 3 hours for 2 days in a dosage of 10,000 units. The temperature quickly fell, and the patient was discharged on the 4th hospital day.

Ten days later he was readmitted, with complaints of continued chills, fever, malaise and severe headaches since arrival at home. At this time, no murmur was noted, but a gallop rhythm was present at the apex. No petechiae were observed, and the spleen was never felt. No organic defects were found on cystoscopy and retrograde pyelography on the 3rd hospital day, but colon bacilli were recovered from the bladder and both ureters. On the 9th hospital day several blood cultures were positive for colon bacilli, and purpuric spots appeared over the body. Intramuscular injections of penicillin (20,000 units every 3 hours) were begun at that time, but the patient became moribund and died on the 12th hospital day.

Autopsy disclosed old, inactive rheumatic inflammation of the mitral and aortic valves, with superimposed acute, ulcerative endocarditis of the left auricular endocardium and mitral valve. Post-mortem blood cultures from the heart were positive for colon bacilli. Focal embolic infarctions were seen in the kidney and spleen, and there were chronic, inflammatory changes in the urinary bladder and urethra.

\*Assistant in medicine, Albany Medical College clinical assistant in medicine Albany Hospital.

**CASE 2** A 56-year-old man was admitted to the hospital on November 7, 1947, with the complaint of shaking chills and fever for 1 week prior to admission. Three weeks before entry, he had undergone urethral dilatation for strictures, and a few hours later he had an episode of violent shaking chills and fever.

The past history revealed an attack of rheumatic fever as a child, necessitating bed rest for 11 months. Since that time, however, there had been no cardiac complaints.

Physical examination revealed a loud systolic and a harsh diastolic murmur at the aortic area, with much fainter replicas at the apex. No external stigmas of embolization were noted at that time, and the spleen was not felt. The remainder of the physical examination was noncontributory.

On the following day, numerous petechiae were noted on the abdominal wall, and several hemorrhagic bullae appeared on the toes of the right foot. Cultures of these bullae were positive for *Staphylococcus aureus* and were man- nite and coagulase positive. Three cultures of blood drawn in the first 2 days were positive for the same or- ganism. Intramuscular injection of penicillin (100,000 units every 4 hours) was begun. New bullae ap- peared on the hands, but the patient improved clinically. Seven days after entry, because of developing cardiac decompensation, the patient was digitalized, a few hours later, the clinical picture of pulmonary embolism was evident. The patient rallied briefly at this point, but 2 days later became comatose and remained so until the time of death, 18 days after admission. Terminally, uremia was present. The penicillin was increased to 100,000 units every 2 hours on the 3rd hospital day, and to 200,000 units every 2 hours on the 5th day. All blood cultures taken after the initial three were negative. No autopsy was performed.

### DISCUSSION

The sequence of events in both cases and the similarity of the organism in the blood stream and urinary tract in 1 case make it evident that the endocarditis had a direct relation to the urethral manipulation. Although urethral dilatation is a common office procedure, such complications make it mandatory to consider the use of prophylactic agents in all persons subjected to these procedures. Persons with a clear history and definite signs of rheumatic heart disease must receive vigorous prophylaxis. The method of choice is not yet certain, but the use of penicillin, with or without sulfadiazine, for two days before and after manipulation has been advised by Glaser et al.<sup>4</sup> and Clark and his associates.<sup>5</sup>

and attributed to mumps<sup>166 167</sup> Actually, fever occurs in considerably less than half the cases and is usually of low grade, constitutional symptoms are minimal, and evidence of other sarcoid manifestations is noted both clinically and at autopsy<sup>91-94</sup> Enlargement of the lacrimal glands may be associated, or may occur with salivary-gland enlargement alone as one form of the Mikulicz syndrome<sup>4 164 165 169</sup> Any of these localizations, however, may develop independently of the others

*Nervous and endocrine systems* Diffuse involvement of the central nervous system has been described on a number of occasions both clinically and at autopsy<sup>89 164 170 171</sup> Lethargy simulating that of encephalitis lethargica may occur and has cleared up with improvement of other manifestations<sup>164</sup> Evidence of peripheral-nerve affection may be noted in the form of pareses and paresthesias or loss of deep reflexes Such findings are rare, however, and may be due to spinal-cord involvement, they constitute a point of differentiation from tuberculoid leprosy in which peripheral-nerve invasion is common<sup>172</sup> Involvement of the cranial nerves, frequently transient may also occur, often in association with the uveoparotid syndrome The facial nerve is most commonly affected, and the resultant palsy is usually of the peripheral type It tends to follow enlargement of the parotid gland, though occasionally it precedes it and may even be an initial symptom<sup>173</sup> Involvements of the auditory, glossopharyngeal and oculomotor nerves may also occur, with resultant deafness, palatal paralysis and varying degrees of cycloplegia<sup>45 92 164 165 174</sup> A case of Adie's syndrome with tonic pupils and absent tendon reflexes has been attributed to sarcoidosis<sup>175</sup> The hypoglossal nerve has been affected on at least one occasion<sup>176</sup> Dysarthria and dysphagia have also been noted but may at times be due to marked dryness of the mouth resulting from salivary-gland involvement<sup>163</sup>

Localization in the hypothalamic region and pituitary gland may be associated with the syndrome of diabetes insipidus, and such localizations have on several occasions been confirmed at autopsy<sup>24 40 70 177</sup> This has not been invariable, however<sup>38</sup> A number of these cases have also been associated with salivary-gland involvement, and in the presence of thirst due to dryness of the mouth, symptoms of polydipsia and polyuria, like dysarthria and dysphagia, must be evaluated with caution

Other stigmas of pituitary-gland involvement have occasionally been noted Kraus<sup>71</sup> has described a case in which polyuria, genital dystrophy, cessation of menses and hypertrichosis were associated with involvement of the pituitary gland and its stalk but this case was unfortunately complicated by a chromophobe adenoma In

another case with panhypopituitarism, the granuloma in the pituitary gland may well have been a tuberculoma<sup>178</sup>

Lesions have been observed in the testis and epididymis,<sup>24 80 94 179</sup> prostate,<sup>24</sup> and thyroid gland<sup>94 100</sup> usually without disturbance Hyperthyroidism in the presence of demonstrable sarcoid lesions in the thyroid gland has been described,<sup>150</sup> but a causal relation seems unlikely In contradistinction to caseating tuberculosis, involvement of the adrenal glands appears to be quite rare

*Gastrointestinal and isolated sarcoid manifestations* Involvement of the stomach and intestines is recorded very infrequently in association with generalized sarcoidosis Occasionally, however, localized lesions have occurred in the stomach,<sup>151</sup> small intestine appendix and colon<sup>29 152-155</sup> and in the regional lymph nodes draining such areas in the absence of manifestations elsewhere

The occurrence of epithelioid and giant cells in some cases of regional enteritis has raised the possibility that the two diseases are related In occasional cases these granulomas are clearly of sarcoid type to the point of massive formation of noncaseating tubercles without evidence of tubercle bacilli even on animal inoculation,<sup>156</sup> but, with one possible exception,<sup>157</sup> such sarcoid lesions have been strictly isolated manifestations In most cases the scattered granulomas seen in the bowel wall in regional enteritis bear only a superficial resemblance to the lesions of sarcoidosis They tend to be small, widely scattered, rather indistinct collections of histiocytes and epithelioid cells, often containing one or two giant cells, and most authors have been content to attribute such findings to foreign-body reaction<sup>158</sup> In at least one case surgical removal of the affected bowel revealed no sarcoid lesions, although evidence of disseminated sarcoidosis existed elsewhere<sup>159</sup> It seems highly unlikely, therefore, that any considerable number of cases of regional enteritis belong in the sarcoid group<sup>40 190</sup>

Isolated sarcoid lesions have also been described in various lymph-node groups, the skin, the spleen and other organs Occasionally, these findings represent temporary localized phases of the disease stabilized in the process of progression or regression In most cases, however, a diagnosis of generalized sarcoidosis is totally unwarranted As pointed out below in the discussion of etiology, a large number of bacterial and chemical agents seem capable of reproducing the histologic features of sarcoidosis For this reason it seems wise to distinguish the *sarcoid lesion* as a descriptive histologic term from *sarcoidosis*, a disseminated disease associated with such lesions<sup>191</sup>

*Miscellaneous manifestations* Occasional localizations have been described in the pancreas,<sup>50</sup> breast<sup>4 35 109</sup> and skeletal muscle<sup>10 47 142</sup> The

noted bone lesions in 29 of 30 cases of lupus pernio, which often involves these areas. Reisner notes a high incidence of skin involvement, disseminated as well as local, in cases with bone lesions. Spontaneous regression of bone lesions appears more likely to take place in the diffuse than in the circumscribed form.<sup>38</sup>

Sarcoid lesions have been demonstrated by sternal-marrow biopsy.<sup>141 142</sup> Dressler<sup>141</sup> also observed some depression of hematopoiesis. Lucia and Aggeler,<sup>143</sup> on the other hand, failed to find granulomas in their biopsies, and the marrow in these areas showed evidence only of mild myelopoietic stimulation as might be seen in any chronic infection.

*Skin and mucous membranes* The incidence of skin manifestations, the oldest and best known of the regional localizations, varies widely with the source of material. In the old dermatologic literature, the incidence of skin lesions is very high,<sup>5</sup> but they have been noted in only 40 to 50 per cent of cases in some more recent series<sup>24 33</sup> and considerably less in others.<sup>47 96</sup> Many forms have been described, including the miliary and nodular sarcoids of Boeck,<sup>2, 3 144</sup> the diffuse, plaque-like lupus pernio of Besnier,<sup>13</sup> the rare erythrodermic form of Schaumann,<sup>145</sup> the subcutaneous sarcoid of Darier and Roussy<sup>146 147</sup> and their variants. All show, on histologic examination, infiltration of the skin with the characteristic granulomas and differ only in the nodularity or diffuseness of the infiltrate, the degree of vascular engorgement and the variable involvement of corium and subcutaneous tissues. They represent, in fact, visible manifestations of the same polymorphism characterizing the roentgenographic pattern in lung and bone, and for this reason, retention of many of the earlier descriptive subtypes has little point. Even the subcutaneous lesions of the "Darier-Roussy" type have been so frequently confused with other conditions, such as erythema induratum and the nodular panniculitis of Weber-Christian, that retention of the term is of little value.<sup>66</sup>

The various skin lesions are described in great detail by various authors<sup>7 8 10</sup> and in textbooks of dermatology. The lesions may persist for long periods or may spontaneously regress in the course of a few months. Regression in one area is associated with a new eruption elsewhere in some cases.<sup>38</sup> Healing may leave no residue or may result in an atrophic scar.

Erythema nodosum occasionally occurs as an early skin manifestation.<sup>5 29 148-151</sup> Since this condition appears to be a more or less nonspecific manifestation of hypersensitivity and is often seen in association with such diseases as rheumatic fever, tuberculosis and coccidioidomycosis, its occurrence with sarcoidosis is particularly interesting. Furthermore, a pulmonary roentgenographic picture identical with that seen in sarcoidosis occurs in

association with erythema nodosum alone,<sup>119 12 13</sup> raising the possibility that some common allergic basis underlies at least part of this clearly non-specific radiologic picture.

Mucous-membrane lesions, essentially similar in character to those in the skin, are described in only 10 to 20 per cent of cases.<sup>5, 10 144 154</sup> but have probably been frequently overlooked. Involvement of the nasal mucosa may produce a stenosis, and involvement of the larynx may produce hoarseness. Lesions have also been noted in the oral mucosa, pharynx, epiglottis and lower respiratory tract, and on at least two occasions, involvement of the bronchial mucosa has been established by bronchoscopic biopsy.<sup>32 99</sup>

*Eye (lachrymal and salivary glands)* Involvement of the eye and its related structures is reported in 25 to 50 per cent of cases in recent series,<sup>24 38 42 47 155</sup> with incidence figures again varying widely with the sources of the material. These figures are substantially higher than older estimates of 5 to 10 per cent<sup>156 157</sup> and clearly represent the now general acceptance of the uveoparotid syndrome as a manifestation of sarcoidosis. Ocular localizations have no special temporal relation to other manifestations,<sup>9 155</sup> but since the attendant discomfort or visual disturbance is more readily noted by the patient than other relatively asymptomatic localizations, they have frequently constituted a presenting complaint.

Eye involvement usually manifests itself as a painless iritis or iridocyclitis, either bilateral or, less commonly, unilateral.<sup>31 155</sup> It occurs in two forms: a benign serous type, and a more severe nodular variety, which may be associated with corneal involvement. Although the lesions may resorb completely—and this has been described even in large nodules<sup>157</sup>—synechiae, corneal opacities, glaucoma and even phthisis bulbi and loss of sight in one or both eyes have been frequently reported and represent serious complications of the disease.<sup>38 155</sup> Conjunctival involvement probably occurs in not more than 5 per cent of cases and may not be associated with other ocular lesions.<sup>40 158 159</sup> Involvement of the posterior uveal tract is rare,<sup>31 155</sup> but choroiditis, retinitis, retinal perivasculitis and optic-nerve involvement have been described.<sup>21, 155 159-162</sup> An occasional complete recovery is reported,<sup>163</sup> but usually the sequelae are serious. Optic-nerve involvement has been associated in most reported cases with involvement of the brain.<sup>91 161 162</sup> and sometimes with diabetes insipidus.<sup>70</sup>

Uveitis, usually bilateral, may be associated with bilateral enlargement of the parotid gland, and frequently of the submaxillary and submental salivary glands as part of a syndrome that has been termed uveoparotid fever.<sup>47, 92 151 164</sup> This complex was first described by Heerfordt<sup>165</sup> in 1909, though similar cases had been reported earlier.

usually tending to be weak.<sup>8 10 205</sup> In Reisner's<sup>38</sup> series, 60 per cent of patients failed to react to doses as high as 10 mg, and 10 of these tested with 100 mg also failed to react. These figures are significantly higher than the expected incidence of nonreactors in an urban population such as the one from which this series was drawn. Unfortunately, however, the majority of reported cases were inadequately tested in the higher and more significant concentrations, and few of the autopsied cases have had an adequate work-up in this regard. Focal reactions to tuberculin have also been negative in such cases.<sup>59</sup>

**Kveim reaction** Intradermal injection of extracts of sarcoid tissue have produced characteristic skin reactions in a number of patients with sarcoidosis.<sup>204-205</sup> The antigen, prepared after the manner of the Frei antigen for lymphogranuloma inguinale, is extremely thermostable<sup>206-208</sup> and seems to be ineffectual unless injected with a large-bore needle in grossly particulate form.<sup>208</sup> The typical reaction, in the form of an indurated and later crusted, occasionally necrotic papule, is slow to evolve, often requiring weeks to reach maximum size and persisting for many months; histologic examination of the sites of the positive tests reveals a granulomatous structure entirely consistent with that of spontaneous sarcoid lesions in the skin. Evanescent early responses first described by Williams and Nickerson,<sup>209</sup> are apparently nonspecific.<sup>206</sup>

The incidence of positive reactions in different series varies. Danbolt and Nilssen<sup>205</sup> produced a positive reaction in 34 of 36 patients tested. Puttkonen<sup>206</sup> found the test positive in 33 of 42 patients and such cases were practically always in an active phase with lesions demonstrable in the skin, lymph nodes or tonsils; the test was almost always negative when the lesions had healed. Nelson,<sup>205</sup> testing a series of 17 American Negroes with sarcoidosis produced characteristic reactions in 7 of 11 active cases, whereas the reactions in 6 inactive cases remained negative. Tests in apparently normal controls have been entirely negative or of low order and negative tests have also been obtained in patients with a variety of skin lesions including leprosy, tuberculosis and lymphogranuloma inguinale.<sup>206</sup>

The typical Kveim reaction, therefore, seems to be rather specific for cases of sarcoidosis, particularly cases with demonstrable activity. The antigen itself, however, is far less specific. Nelson<sup>205</sup> was able to produce identical reactions both clinically and histologically, and in the same patients, using antigens prepared from various sarcoid lesions and from normal human spleen. Similar reactions have also been produced with antigens prepared from the lesions of lymphatic leukemia.<sup>206-208</sup> The histologically characteristic lesions produced in some sarcoid patients with living BCG<sup>210 211</sup> living<sup>212</sup>

or heat-killed<sup>213</sup> human tubercle bacilli and even nonspecific substances such as India ink<sup>214</sup> may well be of a similar nature, and such reactions may also explain the appearance of subcutaneous granulomas following exposure to beryllium compounds and other substances in apparently normal persons. The findings to date suggest an obvious parallel with the history of the Wassermann antigen.

As a diagnostic test, the Kveim reaction is markedly limited by the slow evolution, long duration and occasional severity of the lesions produced. The test also sheds little light on the etiology of the disease but offers a challenging approach to the problem of the pathogenesis of sarcoid lesions.

### *Course and Prognosis*

Sarcoidosis tends to run a prolonged, low-grade, chronic and unpredictable course, ranging in duration from several months to many years. Occasionally, the onset is abrupt and febrile, and a case has been reported in which such an acute onset occurred thirty-six hours after childbirth.<sup>215</sup> Often, however, it is exceedingly difficult to determine the exact time of onset so that estimates of average duration are not too reliable; these have varied in different series from two and two-tenths<sup>20</sup> to eight or more years.<sup>5</sup> In some series individual cases have been followed for fifteen years or more.<sup>38 41</sup> Residual lesions were found at autopsy in 1 of Boeck's early cases twenty-nine years after the original diagnosis had been made,<sup>84</sup> and another case was followed clinically for thirty-four years.<sup>216</sup> The benignity of the course and the generally good prognosis have been repeatedly stressed and it is certain that a considerable number of patients recover completely. In a group of 37 cases with adequate follow-up study reported by King,<sup>30</sup> half of which were confirmed by biopsy, 23 cleared completely or almost completely within three years, 8 showed no change in periods up to four years, and the remaining 3 showed extension. On the other hand, in a series of 28 cases followed by Reisner<sup>38</sup> for an average period of five years, all confirmed by biopsy, regression of lesions to the point of disappearance occurred in only a third. In an additional third the disease was essentially stationary or consisted of alternate periods of progression and regression, and in the final third the disease was progressive to the point of death in 7 cases. In Thomas's<sup>44</sup> series of 15 cases, the results were approximately the same. It is possible that a great many of the published cases have been followed for an insufficient period so that the general excellence of the outlook may have been overemphasized. The high incidence of Negroes in the series of Reisner<sup>38</sup> and Thomas<sup>44</sup> (86 and 80 per cent respectively) may also have had some bearing on the course of these cases, and sarcoidosis in the Negro may in fact, represent a special problem.<sup>217</sup>

serous membranes are infrequently involved, though pleural or pericardial effusion is occasionally seen.<sup>47</sup>

A wide variety of conditions has been described in association with sarcoidosis including Hodgkin's disease,<sup>43</sup> hemolytic anemia<sup>47, 192</sup> and polyarthritides,<sup>142, 193</sup> but coexistence in most of these cases does not necessarily imply causal relation. On the other hand, thrombocytopenic purpura has been recorded with sufficient frequency to be significant,<sup>29, 71, 194-196</sup> and the same observation applies to such an associated syndrome as diabetes insipidus.

**Blood** The white-cell count tends to be within normal limits or low in the large majority of cases, and definite leukopenia has been recorded in a third to a half of the cases in some series.<sup>9, 33</sup> The differential count often shows a mild monocytosis, occasionally as high as 15 per cent, but this is not constant and may even vary from time to time in the same case.<sup>42</sup> However, if monocytosis is accepted as a manifestation in the circulating blood of the reticuloendothelial activity giving rise to epithelioid granulomas, this finding might be expected to occur only during the active phases of the disease if it occurs at all.<sup>4, 23</sup> Mild eosinophilia (counts rarely over 10 to 15, but occasionally as high as 35 per cent<sup>24</sup>) is another inconstant finding, it has been noted in a fourth to a half of the cases in some series.<sup>24, 25, 38</sup>

Changes in the red-cell count or hemoglobin are of little significance. There may be a mild anemia, or polycythemia may occur in association with pulmonary fibrosis.<sup>4</sup> The sedimentation rate is frequently increased,<sup>24, 42, 47</sup> and this has been observed not only in patients in the active phases of the disease<sup>24, 42</sup> but also in patients whose lesions appear well stabilized.<sup>38</sup>

Elevation of the total serum protein, a fact to which Salvesen<sup>123</sup> first called attention in 1935, has since been noted in many cases. The rise may be considerable so that the value may exceed 9.0 gm per 100 cc, and is exclusively in the globulin fraction. The rise in globulin may occur at the expense of the albumin so that reversals of the ratio may be observed even in cases in which the total protein shows little or no increase.<sup>24, 38</sup> Again, these changes are inconstant and, when present, are usually associated with an active phase of the disease, in the healed phases the total protein and albumin-globulin ratio tend to be normal.<sup>41, 43, 197</sup> Electrophoretic studies on the serum proteins have shown that the rise is primarily in the gamma-globulin fraction.<sup>197, 198</sup> The findings are consistent with those seen in other chronic infections, such as lymphogranuloma inguinale and kala azar, and have suggested antibody formation to several investigators.<sup>198, 199</sup> Although Harrell<sup>42, 200</sup> has reported a substance resembling Bence-Jones protein in the urine in 2 cases it has been shown that the

proteins in multiple myeloma present a different electrophoretic pattern.<sup>199</sup>

Elevations in serum calcium, with values as high as 16.5 mg per 100 cc, have also been noted. The hypercalcemia has, on rare occasions, been associated with renal calculi,<sup>29, 130</sup> renal insufficiency<sup>137</sup> and even diffuse metastatic calcification.<sup>128</sup> Hypercalcemia, when it occurs, is often associated with hyperglobulinemia, and some relation between the two has been suggested on the basis of the calcium-binding power of serum protein. The calcium level does not vary in proportion with the protein, however, and may be higher than can be accounted for by the globulin elevation.<sup>34, 200</sup> Furthermore, most of the serum calcium is bound to the albumin fraction, with the globulin increment in hyperglobulinemia binding very little calcium.<sup>201, 202</sup> This suggests that the calcium increment in these cases is in an unbound state and, as such, independent of the hyperproteinemia except so far as each is a manifestation of disease activity. In the inactive phase, the calcium, like the protein, returns to normal levels. The relation of calcium levels to bone involvement is not certain. Hypercalcemia has been noted in both the presence and the absence of roentgenographically demonstrable bone lesions, but it is known that bone involvement may occur in the absence of roentgenographic changes.<sup>7, 123</sup>

In spite of the elevated calcium, serum phosphorus tends to be normal or at most very slightly elevated, the low phosphorus values observed in hyperparathyroidism are not seen. Moderate elevations in the serum alkaline phosphatase have been recorded, but the phosphatase values cannot be correlated with the extent or activity of the bone lesions or with the calcium content of the blood.<sup>200</sup> Cholesterol values in the neighborhood of 130 mg per 100 cc have occasionally been noted.<sup>24</sup> In the absence of renal insufficiency, non-protein nitrogen values are within normal limits.

The various serologic reactions that have been reported have been noncontributory. Serologic reactions for syphilis have been positive in some cases, Gravesen<sup>6</sup> reports only 13 positive findings among 433 patients in the literature so tested, but this figure seems rather low. In this country a higher incidence has been noted, probably owing in part to the high proportion of Negroes in the various series. In several cases positive blood Wassermann reactions have been inconstant, or have persisted in spite of intensive antisyphilitic therapy, suggesting the possibility that some reactions are nonspecific.<sup>38, 164</sup>

**Tuberculin reaction** The high incidence of sarcoid patients who either fail to react to tuberculin or react weakly to concentrations as high as 10 mg or more is a fact upon which practically all authors are agreed. Most estimates of the incidence of such nonreactors range between 60 and 70 per cent of cases, the remaining positive reactions

even in some postprimary disseminated lesions.<sup>120</sup> Whether the organisms are capable of being killed and so completely altered or removed from practically all the lesions that microscopical search and animal inoculations are negative in the great majority of cases is another matter, however, this point has still to be proved, especially since it has been demonstrated that even killed organisms may persist in tissues for some time, retaining recognizable shape and staining qualities.<sup>225</sup>

Several investigators have been attempting to produce specific lesions in sarcoid patients by the use of tubercle bacilli or their products. Positive results have been obtained in some cases with BCG<sup>210, 211</sup> and living or heat-killed tubercle bacilli,<sup>212, 213</sup> but the results are inconstant.<sup>226</sup> As noted above similar responses can be produced by extracts of sarcoid tissue or even leukemic tissue and normal spleen (Kveim antigens). An attempt to invoke characteristic lesions in sarcoid patients with tuberculophosphate has been unsuccessful.<sup>227</sup>

Death, when it occurs, is usually due to pulmonary fibrosis, with resultant respiratory and cardiac insufficiency, or to superimposed cascating tuberculosis. Extensive localizations in vital areas such as the heart, and perhaps the kidney and brain, may also be fatal in some cases. Other serious complications include glaucoma and phthisis bulbi resulting from ocular involvement, and the occasional mutilating effects of bone and skin lesions.

### Treatment

The evaluation of therapeutic measures has been enormously complicated by the marked tendency of the disease to regress spontaneously. A wide variety of agents, including salts of gold and arsenic, chaulmoogra oil, antileprol and others far too numerous to mention, have been tried with equivocal results. Simple measures such as fresh air, sunlight, good diet and rest have been equally satisfactory if not more so.

X-ray therapy has been tried with beneficial effects in a few cases,<sup>43 82 218</sup> and little or no effect in others.<sup>47</sup> More recently, the successful use of calciferol in the treatment of lupus vulgaris has suggested its use in sarcoidosis as well. Curtis and his coworkers<sup>176</sup> report considerable improvement following the use of large doses of both calciferol and dihydrotachysterol. Toxic reactions were present in all cases, however, though no recognized permanent damage was noted, and Lomholt<sup>219</sup> believes that patients with sarcoidosis tolerate calciferol less well than those with lupus.

### ETIOLOGIC ASPECTS

At some time or other practically every agent capable of producing a granulomatous reaction or of diffusely affecting the reticuloendothelial system has been suggested as a possible cause of sarcoidosis. The arguments usually consist in accenting similarities between sarcoidosis and the known disease produced by such agents, at the same time ignoring or minimizing differences. The greater part of the discussion has centered about the possible etiologic role of the tubercle bacillus, most authors since the time of Boeck going on record either for or against. The repeated failures, except on a very few occasions, to identify this organism in the lesions either microscopically or by animal inoculation, as well as the high incidence of weak reactors or nonreactors to tuberculin in the group, have provided the greatest stumbling block to the general acceptance of this theory—though, paradoxically enough, both sides use these findings as their strongest arguments.

### Tuberculosis

The case for tuberculosis has been presented in detail by Pinner<sup>191</sup> whose arguments are essentially those of the many other proponents of this theory. The arguments, both factual and theoret-

ical, that have been mustered on both sides of the question can be conveniently grouped into four categories: bacteriologic, anatomic, immunologic and epidemiologic.

**Bacteriologic arguments.** The identification of acid fast bacilli in sarcoid lesions has been sporadically reported since the time of Boeck.<sup>2</sup> The various positive findings have been listed by Pinner<sup>4</sup> and others,<sup>10 25</sup> and several more have been reported since.<sup>168, 195 220</sup> However, these represent only a minute fraction of cases in which such organisms have not been found, often after exhaustive microscopical search and inoculation into a wide variety of animals.

Attempts to explain this phenomenon on the ground that the organisms are in a filterable form, or have dissociated into nonacid-fast or partially acid-fast forms, are highly theoretical and unconvincing.<sup>102 220 221</sup> On the other hand, if the lesions are actually due to the usual form of the tubercle bacillus, it is necessary to assume that the organisms are quickly killed and disintegrated at their points of focalization under the influence of the local immune forces. Under these circumstances, the lipids of the bacillus might be capable of inducing tubercle formation, as has been demonstrated experimentally,<sup>77 78</sup> whereas the proteins of the bacillus, in the absence of hypersensitivity, produce no significant necrosis or constitutional reaction. Thus, the same immunologic situation responsible for the prompt killing of the bacilli might explain the morphologic character of the lesion.<sup>4 120 222</sup>

If this is true, organisms might be expected to be identified only in very early lesions. Kyrle,<sup>223</sup> in a frequently quoted and controversial case, reported a series of biopsies on a very early skin lesion. Abundant tubercle bacilli were seen on the tenth day together with a nonspecific infiltration of lymphocytes and histiocytes, but a guinea-pig inoculation was negative. By the twenty-first day, the infiltrate was composed largely of epithelioid cells with some giant cells, and the bacilli were much reduced in number, guinea-pig inoculation was again negative. By the thirty-sixth day, the epithelioid-cell foci were free of organisms, contained numerous giant cells and were being encapsulated by fibrous tissue. By the ninety-fourth day, the infiltrate had disappeared. One of two guinea pigs inoculated with blood from the patient during a febrile episode developed tuberculosis. This case is exceedingly difficult to evaluate since it is both unique and atypical.

There is plenty of experimental evidence that acquired resistance to tuberculosis can increase the ability of the body to destroy tubercle bacilli, and the decrease in organisms may be sufficiently marked to render it very difficult to find them even on serial section.<sup>224</sup> It is also known that bacilli may be impossible to find in many primary foci and

murmur heard only in the left lateral decubitus position. The aortic second sound was equal to the pulmonic. The lungs were clear, except for a few crackles at the left base posteriorly. The abdomen was normal. Neurologic examination was negative.

The temperature was 104°F, the pulse 112, and the respirations 28. The blood pressure was 110 systolic, 70 diastolic.

Laboratory studies showed a urine with a specific gravity of 1.018, a + test for albumin, but no sugar or bile, the sediment contained 2 or 3 white cells and 2 or 3 red cells per high-power field. There were no casts. The hemoglobin was 16 gm, and the white-cell count was 13,300, with 83 per cent neutrophils. A stool was guaiac negative. The nonprotein nitrogen was 37 mg and the total protein 6 gm per 100 cc. Six flasks were inoculated with blood, and all grew coagulase-positive *Staphylococcus aureus*. A spinal tap was attempted, but only blood was obtained.

The patient was placed on penicillin, 2,000,000 units a day, digitalized with purodigin and given 75 mg of heparin. On this regime the blood cultures became sterile on the fifth hospital day and remained so. The temperature gradually subsided from daily levels of 103° to 104°F to 99° to 101°F in the course of two weeks. Despite these improvements he remained drowsy, had occasional bouts of hiccuping, but complained only of poor appetite. Approximately two weeks after admission the nonprotein nitrogen was found to be 160 mg per 100 cc. Additional laboratory studies showed the urinary specific gravity to be 1.008, with a ++ test for albumin and rare white cells and red cells in the sediment. The urine culture showed *Bacillus pyocyaneus* (*Pseudomonas aeruginosa*). The blood sodium was 123.4 milliequiv, the chloride 90 milliequiv, and the carbon dioxide 25.8 milliequiv per liter, and the calcium was 8.7 mg and the phosphorus 6.4 mg per 100 cc. The blood pressure was 190 systolic, 110 diastolic. Repeated blood cultures were negative. Four days later rapid breathing, increase in the pulse to 140 and moist rales in the lungs suddenly developed, clearing rapidly with morphine and tourniquets. In spite of therapy he showed little improvement in his general condition, and the urinary output, which had been maintained at 1500 to 2000 cc a day, dropped sharply to less than 500 cc a day, averaging about 350 cc. The urine specific gravity was 1.005. There was a ++++ test for albumin and many white cells and rare red cells in the sediment. The white-cell count rose to 22,000, with 86 per cent neutrophils, 9 per cent lymphocytes and 5 per cent eosinophils.

The course was steadily downhill, and approximately one month after admission the lungs suddenly became filled with bubbling rales, and the patient became sweaty and apprehensive. The

blood pressure was 210 systolic, 130 diastolic, the pulse 160, and the respirations 10. He failed to rally and expired soon after the onset of this episode.

#### DIFFERENTIAL DIAGNOSIS

DR ALFRED KRANES: May we know when this diminution in the urinary output took place? It is not quite clear from the record. I wondered whether the nonprotein nitrogen rose in the presence of a normal urinary output during the first weeks and with a normal specific gravity.

DR RITA M. KELLEY: The nonprotein nitrogen rose while the output was still adequate, but the specific gravity became low, only in the last few days was the output poor. The nonprotein nitrogen rose steadily and was elevated for about ten days before death.

DR KRANES: The nonprotein nitrogen began to rise at the end of two weeks, but the patient lived a month.

DR KELLEY: That is right, but the decrease in output came only a few days before death.

DR KRANES: Therefore it rose in spite of a normal urine output, with a low specific gravity. Might I ask whether the specific gravity rose?

DR KELLEY: It never rose.

DR KRANES: We are faced with a man who came in with an acute fulminating *Staph. aureus* septicemia, which was promptly recognized and treated, and who died one month later with one of the complications of renal insufficiency—namely, acute pulmonary edema.

As I see the problem we are asked to try to guess what was the trouble with the kidneys. So far as the acute episode that brought him in is concerned, the record is fairly clear-cut, although exactly what the portal of entry for the staphylococcus was is not at all clear. Very often we do not know just how invasion took place. In this case, since the man was a carpenter, he may have had what seemed to be an insignificant skin infection, and from that, very virulent organisms entered the blood stream, producing the picture described. He may have had an acute sinusitis or ethmoiditis. I do not see how we can possibly guess the origin of the septicemia. Whether or not he had a bacterial endocarditis is also a guess. He probably did, although not primary. The chances that the organisms landed on one of the heart valves are certainly fairly great in this particular case, in which we have reason to believe mitral rheumatic heart disease existed, probably mitral stenosis. There is a fairly good probability that he had an acute bacterial vegetation engrafted on the mitral and possibly on some of the other valves. Do we know any more about the murmur?

DR KELLEY: The mitral diastolic murmur remained the same. There were no new murmurs.

DR KRANES: Presumably mitral stenosis and possibly acute bacterial endocarditis.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., Editor

BENJAMIN CASTLEMAN, M.D., Associate Editor

EDITH E. PARRIS, Assistant Editor

### CASE 34451

#### PRESENTATION OF CASE

A forty-one-year-old carpenter entered the hospital because of fever and delirium.

The patient had been well and active until two days before admission, when he developed a slight cough, a feeling of tightness in the chest and a mild headache. The next day he refused his breakfast but reported for work only to return home shortly, complaining of cough and headache. He went to bed with a shaking chill and a temperature of 103.5°F. Sixteen grams of sulfadiazine was prescribed and taken in divided doses during the next

twenty-four hours. Despite this he grew gradually less responsive and became delirious, with continuance of the high fever. He was then given 300,000 units of penicillin in oil and sent to the hospital.

The past history revealed an episode several years previously of ankle pains, which were severe enough to cause him to stay in bed a month. A few years later he was told that he had a heart murmur. He had had frequent colds and a chronic, non-productive cough. Since his father's death from cardiac disease five months previously, he had been considerably concerned about heart disease and began to complain of pain in the anterior chest and mild exertional dyspnea although there was no orthopnea, ankle edema or palpitation.

Physical examination showed a well developed, obese man who was semistuporous, warm, flushed and sweating. There were a few questionable petechiae on the arms, neck and buccal mucosa, and small, blotchy, pink macules on the trunk and legs. The eyes were not remarkable although the fundi were not seen. The throat was slightly injected. The ears were normal. The neck was supple, and there was no venous distention. The heart was enlarged, the border of cardiac dullness extending 2 cm beyond the midclavicular line. There was tachycardia with frequent extrasystoles. There was a Grade II, rumbling, diastolic, apical

would be the most likely etiology, although there are certain aspects of the picture that are atypical. The other possibilities that I have mentioned cannot be ruled out.

DR MERRILL SOSMAN: Was the brain removed at autopsy, Dr Mallory?

DR TRACY B MALLORY: No.

DR SOSMAN: Then there is no use speculating about that. I might ask Dr Kranes what he expects to find in the heart—whether or not it will be an acute bacterial endocarditis.

DR KRANES: An enlarged heart with rheumatic mitral disease and probably some acute bacterial vegetations containing *Staph aureus*.

DR SOSMAN: Do you think that the renal lesions could have been embolic?

DR KRANES: You mean the type of embolic glomerulonephritis found with *Streptococcus viridans*? There is no evidence in this case that *S viridans* was found. I hesitate to make a diagnosis of two organisms when only one is presented to me.

DR MALLORY: Will you tell us about the impressions of the clinicians on the ward, Dr Kelley?

DR KELLEY: Most of us thought that it was probably an acute nephritis. We did not know the amount of sulfonamide administered until later when the patient's physician came in. At that point we inclined to acute diffuse nephritis on the basis of the maintenance of the penicillin blood level, ten times the sensitivity of the organism. We believed that the infecting organism had been controlled by the penicillin.

DR MALLORY: How did you explain the fever?

DR KELLEY: He also had a slightly infected urine because he was maintained on constant catheterization since he was unable to void spontaneously.

DR JOHN B QUINBY: Are the urinary findings, the first ones, adequate to rule out the thought of a pre-existing element of renal failure based on old pyelonephritis?

DR KRANES: No, that is always possible in a perfectly healthy man. One must remember that a patient can have renal disease and maintain excellent health. I think it is possible but not probable.

#### CLINICAL DIAGNOSES

Acute glomerulonephritis  
Acute pulmonary edema  
Acute bacterial endocarditis  
Rheumatic heart disease  
Cystitis

#### DR KRANES'S DIAGNOSES

Rheumatic heart disease  
*Staph aureus* septicemia  
Acute bacterial endocarditis  
Acute nephritis caused by sulfonamide nephritis

#### ANATOMICAL DIAGNOSES

Endocarditis, acute bacterial (*Staph aureus*),  
mitral and aortic valves, healing  
Endocarditis, rheumatic, old, mitral and aortic  
valves  
Glomerulonephritis, acute  
Arteriosclerosis, coronary, severe, aortic, mild  
Myocardial infarct, old  
Infarcts, recent, kidney and spleen  
Cystitis, acute hemorrhagic

#### PATHOLOGICAL DISCUSSION

DR MALLORY: Autopsy showed a very much enlarged heart, weighing over 500 gm, with evidence of old rheumatic damage to both mitral and aortic valves. The mitral valve had, in addition, a very large, friable vegetation, measuring nearly 3 cm in diameter, and there were a few, very small, acute vegetations on the aortic valve. There was a large area of scarring in the myocardium, and on examining the coronary arteries we found that they were reduced to almost pinpoint lumens. So we had two possible sources for the myocardial scars: emboli from the acute endocarditis and coronary sclerosis. The microscopical sections suggest that both played a part. A portion of the scarring was very old, obviously many months if not several years in age—completely healed, fibrous scars with no trace of the necrotic muscle cells. In fact, there was slight replacement of the scar by adipose tissue. These scars must have long antedated the endocarditis, and I ascribe them to the coronary-artery disease. There were also, however, many small foci of acute myocardial necrosis scattered throughout the heart, which I think were undoubtedly due to emboli. The kidneys were the major point of interest. They were extremely enlarged, with very thick, pale cortices, and showed typical acute diffuse glomerulonephritis. There were infarcts in the spleen and in one of the kidneys, evidently secondary to the endocarditis, and a very severe terminal pulmonary edema with old, calcified scars in the pleura near the base, the etiology of which I am uncertain about, but they were probably tuberculous.

Glomerular lesions can occur in the ordinary type of *S viridans* endocarditis in two forms: involvement of scattered glomeruli or of portions of individual glomeruli, which is ordinarily called embolic glomerulonephritis. That is the common type and does not usually lead to renal insufficiency, although generally associated with red cells in the urine. In about 10 per cent of endocarditis cases a diffuse glomerulonephritis develops. I think that this is the first case of diffuse glomerulonephritis that I can remember in which the nephritis was associated with staphylococcal rather than strepto-

Were there any x-ray films, and are they helpful at all?

DR JOSEPH HANELIN The patient was too ill to have conventional films. The films were obtained with the patient recumbent, this being an anteroposterior instead of the usual posteroanterior projection. The heart is large. Despite the magnification it looks larger than one would expect to see it in this position. There is a density superimposed on the right side of the heart, which may represent an enlarged left auricle. The lung fields are probably clear, and these little circular densities throughout the lung probably represent vascular shadows rather than metastatic abscesses. The spleen is perhaps just visible — if that is the spleen, it does not appear enlarged. The bone structures are normal.

DR KRANES When, during the course of the illness, was this film taken?

DR KELLEY On admission.

DR KRANES In the days before intensive chemotherapy, the patient probably would have died within a few days or a week after admission, and the chances are that at autopsy many metastatic abscesses would have been found in various parts of the body, most commonly in the kidneys, brain and myocardium — the sites most commonly affected. Whether, despite the intensity of treatment, residual abscesses remained is impossible to say on the evidence. There is no evidence of myocardial involvement except for two attacks of acute pulmonary edema. There was certainly no evidence of cardiac tamponade. The patient ran a temperature of 101°F in the hospital, so presumably the infection may not have been completely healed.

The real problem is not so much the bacterial infection as the nature of the renal lesion. Time was when in a case of this sort we would be satisfied to make a diagnosis of acute nephritis and let it go at that, but nowadays we are expected to try to predict what the microscopical lesion will be. I find that quite impossible, but I see no reason why we should not look over the possibilities. In this particular case there were many factors operating that may have produced renal damage. In many cases of kidney disease we are hard put to find the cause. There are many possible causes here. The first and most obvious one is the large dose of sulfadiazine that he received on the day before admission — 16 gm in twenty-four hours. One wonders what role sulfonamides played in the production of this picture. As you know, sulfonamides may produce renal damage in any one of four ways. They can plug up the tubules, they can produce a lower-nephron nephrosis, they can cause an acute interstitial nephritis involving neither the tubules nor the glomeruli, and they can produce acute necrotizing arterial lesions similar to those found in periarteritis nodosa. These were first described

by Rich\* several years ago, and since then isolated case reports have appeared in which periarteritis-like lesions are found following sulfonamide administration, the patients frequently dying in uremia. Which one of these may have been operating in this case I find it difficult to say. I think we can rule out the first one — that is, plugging of the tubules, since there was no anuria. Lower-nephron nephrosis, also, usually leads to striking oliguria or anuria, which this patient did not have. I think it would be unusual for a person with lower-nephron nephrosis to have an adequate urinary output for so long and to develop azotemia. The other two types I cannot rule out. It is conceivable that he had a periarterial lesion or interstitial nephritis due to sulfonamide. As for acute glomerulonephritis, one would expect a good deal more hematuria than described here. I think we must assume that this patient did have an acute lesion, since there is no evidence that the kidneys had previously been involved in any way. On the law of chances I think that glomerulonephritis is very unlikely.

One naturally wonders whether the kidney disease could possibly be linked to the primary illness. Can the staphylococcus be incriminated in this case? As I said before, in the prepenicillin and pre-sulfonamide era this patient would have died in several days with evidence of septic emboli in the kidneys, either several discrete abscesses or miliary abscesses of the cortexes. As I read this, I wondered to myself, although I have never seen it described, whether if such a patient were kept alive with chemotherapy and the septic element controlled, he might live long enough to develop renal insufficiency from these lesions. I have never heard of it, but I think it is not improbable. One might find diffuse miliary abscesses throughout the cortexes of the kidney interfering with renal function. We are dealing here with a virulent organism that was coagulase positive and may not have been reached by penicillin.

While on the subject of the staphylococcus, I suppose it is not too far-fetched to bring up one other possibility, although again I hesitate to mention it because of its rarity. That is bilateral cortical necrosis. These cases are described chiefly in women, the majority of them occurring after delivery. A few cases have been described in men, however. The reason I mention it here is that lesions like bilateral cortical necrosis have been produced experimentally in animals by the injection of staphylococcus toxin. Since this patient suffered from a severe staphylococcal septicemia, one wonders if it could possibly have been a source for the renal lesion.

I have no way of choosing among these various possibilities. I am forced to make a guess. On the law of probabilities I should think that sulfonamides

\*Rich A. R. Role of hypersensitivity in periarteritis nodosa as indicated by 7 cases developing during serum sickness and sulfonamide therapy. *Bull. Johns Hopkins Hosp.* 71:123-140, 1942.

this patient became distended very promptly as soon as the enema was given, it might mean that the enema fluid escaped from the colon into the peritoneal cavity, especially if the distention was attended by sudden, severe, abdominal pain. On the other hand, perforation of the colon is rare as a result of enemas. It is a very unusual occurrence in my experience, with the exception of instrumental perforations, which occur while a colostomy is being irrigated or something of that sort or in the presence of a lesion in the wall of the colon itself. Carcinomas of the colon rarely perforate. On the other hand, perforation of the colon, proximal to an obstructing carcinoma, is not infrequent. We have seen such things occur with an overdistended colon when a perforation of the cecum may occur as a result sometimes of an enema given in the X-Ray Department. Lymphomas sometimes perforate and diverticula of course do.

The cervical lymph node must have been pathologic. It was apparently a single mass, suggestive of involvement of one of the lymph nodes with carcinoma or some other malignant tumor, possibly lymphoma. Could it have been related to anything within the abdomen? The Virchow node, which we read about in textbooks but rarely see, does occur in carcinoma of the stomach and esophagus, sometimes occasionally from other abdominal carcinomas but not very frequently.

No peristalsis was heard except during paroxysms of pain, when a few, scattered, high-pitched sounds were audible. That is an important observation. After twenty-four hours of peritonitis it is a little bit unusual for a patient still to have peristalsis detected by auscultatory methods. One occasionally hears it, but it is distinctly unusual.

The tender mass in the pelvis is of interest. The average malignant tumor in the pelvis arising from the genital tract is not particularly tender. On the other hand, if one has a carcinoma arising in the bowel, it may well be tender because of secondary inflammation from infection. This could have been, I presume, a purely inflammatory mass.

This patient died, obviously of peritonitis, sixty-four hours after the sudden episode of pain and distention. Can we connect this whole history and try to make one diagnosis, or do we have to make several diagnoses? I am inclined to make more than one, but I must confess I do not know what exactly was wrong with her. I think it is fair to say, on the basis of the history, that she must have had gallstones and difficulty with the gall bladder because of certain aspects of the history, such as intermittent colicky pain in the upper abdomen. The fact that this followed a period of jaundice and that when it occurred the jaundice disappeared lends a certain amount of weight to the possibility of gallstone ileus. She may have had a large stone, which had entered the intestinal tract and passed down slowly, causing intermittent attacks of pain, and had ultimately lodged. I cannot remember a

case of gallstone ileus in which a stone of sufficient size to obstruct the small bowel had passed through the common duct. Those that I am familiar with had ulcerated through into the abdominal cavity from the common duct across an abscess or an area of necrosis into the duodenum or from the gall bladder directly into the duodenum. Dr Mallory perhaps would like to comment on that as a generality. But it seems to me that if we are dealing with gallstone ileus, which should be thought of, a more definite, acute, inflammatory process in the right upper quadrant should have been observed at some time or other in the past. We have no such observation. The only symptoms and signs that point toward the gall bladder are those of obstruction and not inflammation. So, although it possibly should be mentioned, on the basis of the history it seems to me that that diagnosis does not have sufficient weight.

Another important question to decide is whether the peritonitis that the patient died of arose as a result of the enema. One would think so from the way the history reads. She was all right except that the bowels did not move for twenty-four hours, which does not seem unusual, but she was given an enema and then the abdomen immediately became distended and she developed pain, which suggests perforation. Let us assume that the peritonitis did arise from perforation of the colon. I do not believe it came from perforation of the small bowel by the way of an enema. If the perforation and the peritonitis were the result of an enema, it must have been from the colon. Therefore, one would have to assume that there was some intrinsic lesion in the colon. The gall-bladder disease with jaundice, with some of the other things the patient had, and the type of pain, which was entirely in the upper abdomen, suggest either small-bowel obstruction or pancreatitis or perhaps gall-bladder colic. She probably had a mass in the pelvis. This mass was tender and irregular. It could have been malignant in the sense that it was a malignant neoplasm and it could of course have arisen in the bowel, in the sigmoid or in some other loop that lay within the pelvis. There is nothing to suggest that it arose from the retained cervix, which felt normal, though on motion of the cervix the patient experienced pain.

That is as far as I can go with a situation such as this. If we assume that the peritonitis, which she died of, arose as a result of the giving of an enema, I think we must also assume that she had some lesion of the colon, possibly the sigmoid, and that it probably was inflammatory, either primarily inflammatory or a growth of some kind that was secondarily inflamed. If we assume that that was the case we have to neglect some of the important aspects of the history that have to do with the gall bladder.

DR DANIEL S. ELLIS: I should like to ask Dr Sweet if he would consider the possibility of a malignant lesion perhaps involving the pancreas or the

coccal infection. There can be no doubt about the organism, however. It was grown repeatedly.

DR KRANES: How about the absence of hematuria? Or was there hematuria in this case? Is that not a bit unusual?

DR MALLORY: There may have been more than was apparent in the record.

DR KELLEY: No, there was never very much

## CASE 34452

### PRESENTATION OF CASE

A sixty-nine-year-old woman was admitted to the hospital because of abdominal distention and lower suprapubic pain.

Thirty-eight years before admission a hysterectomy had been performed because of fibroids. Ten years before admission during a routine physical checkup including x-ray examination, a nonfunctioning gall bladder was discovered. The patient at this time admitted an intolerance to fried and fatty foods of thirty years' duration. Eight months before admission the patient was awakened in the early morning by a sharp, excruciating, right-upper-quadrant pain, which radiated to the scapula. The acute episode passed off after several hours, leaving residual soreness. There was no associated nausea or vomiting, dark urine, acholic stools, jaundice or chills and fever. During the six weeks that followed she had several recurrent attacks of right-upper-quadrant pain. Five months before admission she noted failing appetite, loss of weight, weakness and lethargy. Two months before admission she became jaundiced and complained of itching. She could not report on the color of stools and urine. Chills and fever were absent. She did have daily nausea and vomiting until admission. The weight loss by now had amounted to 24 pounds. Two weeks before admission it was discovered that the blood sugar was 390 mg per 100 cc, whereas the value had been normal two weeks before. The jaundice subsided in the four weeks preceding admission. During the two weeks before admission the patient complained of epigastric pain radiating through to the back and she noticed a lump in the neck. Twenty-four hours before admission an enema was given because she had had no bowel movement for twenty-four hours. The enema was not expelled, and she suddenly became distended and complained of lower abdominal, suprapubic pain. The vomiting continued without change. At the time of admission she had passed no gas by rectum.

Physical examination showed a left supraclavicular lymph node that was enlarged, firm and freely movable. The heart was not enlarged, and there was a Grade II systolic murmur at the apex transmitted to all areas. The abdomen was distended and

diffusely tender. No peristalsis was heard except during the patient's rare paroxysms of pain, when a few scattered, high-pitched sounds were audible. On pelvic and rectal examination there was a large, retained cervix, which could not be visualized. There was a very tender mass in the cul-de-sac, which felt lobulated. This mass was continuous with the cervix, motion of which caused severe pain. There was a small amount of soft feces in the rectum that was guaiac positive. The white-cell count was 24,000.

The temperature was 97°F, the pulse 90, and the respirations 20. The blood pressure was 118 systolic, 70 diastolic.

Shortly after admission the patient rapidly went into shock, the blood pressure was unobtainable, and the pulse was 140. Distention and generalized tenderness were increased. Rigidity and rebound tenderness were present. The temperature at this time was 101°F. In spite of blood transfusion the patient never recovered from shock, and the temperature reached 107°F terminally. She died thirty hours after admission.

### DIFFERENTIAL DIAGNOSIS

DR RICHARD H. SWEET: This woman had a long history of encounters with the medical profession. The hysterectomy done thirty-eight years before admission undoubtedly was a supravaginal hysterectomy, leaving the cervix.

The episode eight months before admission is rather characteristic of gallstone colic. It is very frequent for a patient to have gallstone colic in the absence of nausea and vomiting. If infection is absent, one need not see changes in the temperature, pulse and white-cell count. If the stone does not pass through the cystic duct, there is, of course, no jaundice. One can relate all these symptoms to gall-bladder disease except the lump in the neck. She could have had, to explain the later difficulties, increasing trouble with the gall bladder, a mild or moderate degree of infection and passage of the stone into the duct, with jaundice and all the characteristic signs of obstruction — perhaps subsequent release of the obstruction because of passage of the stones into the intestinal tract.

I do not know why she developed a high blood sugar. There is nothing else to suggest that she had pancreatitis, although she complained of pain radiating to the back, which might go with it.

How can the lump in the neck be connected with gall-bladder disease? It may have been a metastasis from carcinoma of the gall bladder. Anyone who has had gallstones for a period of many years is likely to develop a carcinoma. Conversely I at least have never seen a carcinoma of the gall bladder develop in the absence of stones, although it may, of course, be found. The lump in the neck which developed out of a clear sky, is an important finding. Of course one should not place too much emphasis on the wording of these histories, but if

## FAMILY REUNION

MASSACHUSETTS, the Mother of many outstanding figures and accomplishments in public health, will be able to view her children and see how they have developed when the American Public Health Association celebrates its seventy-sixth birthday with a meeting in Mechanics Hall, Boston, from November 8 to 12.

Just a hundred years ago the Massachusetts Medical Society was joining the American Statistical Association in petitioning the Legislature to establish a commission to survey sanitary conditions within the Commonwealth. The immediate result was the masterly report of Lemuel Shattuck and his associates, submitted April 25, 1850, and ultimately the first state board of health, with which

Massachusetts set the pattern for the whole country nineteen years later.

The continued Massachusetts contribution is highlighted in the current presiding officers of the American Public Health Association. The president and first woman to hold this office, Dr. Martha Eliot, associate chief of the Children's Bureau, comes of a distinguished Boston family to which she adds lustre. The president-elect is Dr. Charles F. Wilensky, an authority who has made himself indispensable locally and nationally in both public-health and hospital fields. His official positions as director of the Beth Israel Hospital and deputy commissioner of the Boston Health Department give only an indication of his broad community service.

The American Public Health Association has become a very influential and representative organization of twelve thousand members including professional workers in all branches of public health. Twelve sections will be holding scientific sessions, and a great many discussions will vitally interest practicing physicians. A special session honoring Lemuel Shattuck will be held on November 10.

During the twenty-five years since the American Public Health Association last met in Boston public health has developed enormously. As the mother of so much of the best in public health, Massachusetts has a tremendous interest in seeing what manner of men her children have become. Her cordial greeting will be heightened by a maternal interest in how the offspring have fared in other environments and, as children returning from far places, in the new ideas they will doubtless introduce into the "home."

## DIAMOND ANNIVERSARY OF NURSING

Nursing Progress Week, beginning on November 14, has long been in preparation. In planning for it the American Nurses' Association has done a truly admirable piece of work, organizing a nationwide demonstration that will reach its peak on Linda Richards Day, November 16. It deserves the nation's attention.

Nursing, in one form or another, is an ancient calling, devoted to the care of those who cannot

ampulla of Vater as a cause of the pain rather than stone

DR SWEET I neglected to mention it, though it ran through my mind as I read the history over I tried to explain the pain in the back and also the change in the picture that was characteristic of the appearance of that pain and prolonged nausea, which often occurs in pancreatic disease Carcinoma of the pancreas may cause intermittent jaundice, so we need not exclude the diagnosis of carcinoma of the pancreas because of the fact that the jaundice cleared Of course the lymph node in the neck, if it was malignant, could have been secondary to carcinoma of the pancreas as well as to other things — the lymphatic channels intercommunicate

DR ELLIS One might also explain the hyperglycemia on that basis

DR SWEET That was a rather sudden development, was it not?

DR ELLIS I thought it was carcinoma of the pancreas or even of the ampulla of Vater, causing the onset of diabetes along with the onset of the original symptoms In 2 cases that I know of, disappearance of symptoms, including the diabetes, was noted when the major lesion was detected

DR W PHILIP GIDDINGS We had this patient as a private case for a short period She was brought here from another hospital, where the enema had been given She had a normal gastrointestinal series and a negative barium enema, both within a few weeks According to the patient, the interval between the enema and the distention and discomfort was very brief But according to those who gave the enema and the doctor in the other hospital, there had been a distinct interval, and the onset of the change was by no means sudden or agonizing On that basis I was inclined to believe that it was not perforation of the colon We all thought that she had a perfectly good history of gall-bladder disease, and we thought that stones were present The lymph node in the neck, which was a little above the supraclavicular area, actually was very hard, and there was no question in our minds that it represented a metastatic cancer We questioned gallstone ileus as Dr Sweet did, but it did not seem to fit She had been under continuous medical observation for eight months, and we were informed that the diabetes had developed suddenly, on that basis and because of the node in the neck, we thought that we were dealing with carcinoma of the pancreas The presence of peristalsis when she first came in did not seem compatible with peritonitis of twenty-four hours' duration, as it did not to Dr Sweet Our original impression was that she had abdominal carcinomatosis from carcinoma of the pancreas The terminal event that started four hours after admission was rather dramatic The passage into shock was very rapid The increase in abdominal tenderness was very marked, and the rebound tenderness and so forth described did not appear until the final severe episode, but at that time it became

apparent to us that she obviously had peritonitis as well and we were unable to state its source

#### CLINICAL DIAGNOSES

Rupture of abdominal viscus  
General peritonitis  
Carcinoma of stomach?  
Carcinoma of pancreas?

#### DR SWEET'S DIAGNOSIS

Generalized peritonitis from perforation of colon at site of inflammatory, malignant lesion

#### ANATOMICAL DIAGNOSES

*Adenocarcinoma of pancreas, with metastases*  
*Perforation of metastatic carcinoma of ileum forming pelvic abscess*  
*Peritonitis, acute generalized*

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY When the peritoneal cavity was opened there was obvious diffuse peritonitis, which, because of the slight turbidity of the fluid, appeared quite fresh In the pelvis there was a partially localized collection of pus that seemed to have been present for a rather longer time, perhaps for weeks even On examining the bowel we found multiple tumor nodules, all of which, however, seemed to be involving the bowel from the serosa inward The distribution was rather peculiar One of these nodules had almost completely encircled the pylorus, producing quite marked pyloric stenosis A second was in the ileocecal valve and likewise was quite stenotic She had a Meckel diverticulum, but it was not perforated About halfway between the Meckel diverticulum and the ileocecal valve was a perforation about 0.5 cm in diameter in one of these multiple neoplastic areas Further search showed that the primary carcinoma was in the pancreas Approximately three quarters of the organ was destroyed by tumor The gall bladder was dilated and thin-walled, and we found no stones in the gall bladder or bile duct So we believe everything is explained by carcinoma of the pancreas and the metastases I cannot say whether or not the enema had anything to do with the perforation in the small bowel, which was a considerable distance above the ileocecal valve — probably not

DR GIDDINGS I believe, Dr Mallory, that there was one more interesting feature about the autopsy — the site of the perforation in the ileum was in a loop that was fairly adherent in the right pelvis as the result of an old, fibrous band, which was pretty obviously a result of the hysterectomy

DR MALLORY Yes The bowel was sharply angulated, and the tumor nodule was in the site of the angulation, with the perforation in that knuckle Whether that mechanical fixation had anything to do with the metastasis at that point is questionable.

on, Dr James A. Spalding, who presented the collection to the Boston Medical Library

The Library has also been the recipient of many outstanding gifts from public-spirited citizens who believed in placing valuable documents in local institutions where they could be properly safeguarded and preserved for posterity

In this connection there may be noted the receipt book, dated 1643, of Governor John Winthrop of Massachusetts, a collection of medical letters, written between 1652 and 1663, of his son, John Winthrop, governor of Connecticut, the documents of Dr James Thacher, of Plymouth, covering the years from 1754 to 1844, and recently supplemented by a collection of twenty-three letters, the original records of the secretary of the Milton Vaccination Committee, dated 1809, giving in detail the story of the famous experiment of inoculation and vaccination of the children of the town, the records of inoculations and vaccinations from 1775 to 1800, at Rainsford Island, in Boston Harbor, and the original depositions of various prominent physicians and other persons given in Suffolk Superior Court in 1853 on the petition of William T G Morton, regarding his right to use ether as a surgical anesthetic, and other valuable documents that have found a permanent abode in the Library

Where material of local value cannot be obtained by gift, every effort should be made to acquire it by purchase. Booksellers and book scouts occasionally come into possession of such material and usually offer it to local libraries or societies. It is regretted that some institutions do not recognize the necessity of owning all documents of local interest and, rather than spend a few dollars, permit the material to go elsewhere

Dr Spalding was a good friend of the Boston Medical Library, and it was through his efforts that the collection of original sketches and drawings of the anatomist, Alexander Ramsey, made between 1721 and 1824, were rescued from a closet in a New Hampshire farmhouse. The director of the Library recalls driving one brisk October morning to Portland, Maine, to see Dr Spalding, and then driving another hundred miles into the mountains and having to listen to a broadcast of a world-series game before any business could be transacted,

reminding one of tea-time and the Saturday holiday in London, where likewise business cannot be considered during these sacred hours. However, negotiations were conducted satisfactorily, and the drawings are now in Boston

Dr Frederick C Shattuck, 1847-1929, a prominent physician of Boston, with a national reputation, saved all the letters received by him from other physicians throughout the country and from time to time turned them over to the Library. Such letters are valuable for their contents or their signatures, and all such current correspondence unless privileged should be preserved and presented to local institutions

Dr H Winnett Orr, the eminent orthopedic surgeon of Lincoln Nebraska, who invented the Orr method of treating osteomyelitis, is also historically minded. He systematically assembled in fifteen folio scrapbooks a mass of material on his personal and family affairs, on the history of orthopedics and on osteomyelitis, wound treatment and fractures. Volume Six constitutes a history of the first American orthopedic unit to England and France from 1917 to 1919. In 1921 Dr Orr wrote an interesting pamphlet entitled *An Orthopedic Surgeon's Story of the Great War*. The scrapbook of 365 pages contains a mass of documentary and photographic material relating to the unit. In the back there is a long manuscript by Dr Orr on the history of the orthopedic service of Base Hospital No 8, American Expeditionary Forces. Dr Orr, recognizing the outstanding local importance of his scrapbook, very generously presented it to the Boston Medical Library. It is hoped that in the future all documentary material relating to the medical profession in any way will be preserved and deposited with appropriate libraries or institutions

## LO, THE POOR ESKIMO

A BCG-vaccination program among the Eskimos at Point Barrow, Alaska, has been completed, according to the Bureau of Indian Affairs. The initiation of a medical survey on Navajo-Hopi reservations in Arizona and New Mexico, conducted by a team selected by the American Medical Association, under the leadership of Dr Louis J Moorman of

care for themselves. It was a group activity, semi-organized, and largely on a religious basis before the Middle Ages. It was not until the early nineteenth century that the roots of modern training struck into fertile soil at Kaiserswerth, under the guidance of Pastor Fliedner, and it was here that Florence Nightingale found the inspiration that was to be her own lifelong guiding influence. Nursing became a profession when she later organized the school at St. Thomas' Hospital in London.

In America the first professional school for nursing was established in 1872 in Boston, at the New England Hospital for Women and Children. Linda Richards was its first matriculant and in the following year became America's first graduate nurse. In 1873 schools for nurses were established at Bellevue Hospital in New York, where Linda Richards, after her graduation, became night superintendent, at the Massachusetts General Hospital, and at New Haven, Connecticut, where the Connecticut Training School for Nurses came into existence.

The "Boston Training School" as it was first called, which had been established at the Massachusetts General Hospital, welcomed Linda Richards as its own superintendent in 1874. In 1877 she went to England to study nursing methods in the school at St. Thomas', returning in the same year to organize the training school at the Boston City Hospital.

So it is that in 1948, seventy-five years after the first trained nurse was graduated and these three eminent schools of nursing were founded, the Diamond Jubilee of Nursing in America is appropriately celebrated.

There must be other purposes for a jubilee than the recapitulation, however proudly, of seventy-five years of progress by a profession. The American Nurses' Association, with 162,000 of the 320,000 registered nurses in America in its membership, has set itself to the recruitment of the 40,000 additional students needed for approved schools. It is directing attention to the necessity for the extension and improvement of nursing service to all through the improvement of schools of nursing. It is promoting "economic security for all nurses, adequate licensure laws and more effec-

tive counseling and placement of both prospective students and graduate nurses."

Thus the struggle goes on for all groups, seeking higher standards of achievement and better standards of working and living. The problem that still defies solution is the basic economic one of payment and where it is to come from.

---

## MANUSCRIPTS AND MEDICAL HISTORY

MANUSCRIPTS are the source material of medical history. Occurring in the form of diaries, account books, case records, biographical collections and single items, letters, bills, recipes, treatises and miscellaneous documents of all periods, including the present, they should be preserved and deposited in permanent sanctuaries for the benefit of scholars and other interested persons.

The correspondence and other documents of eminent physicians of the twentieth century will be valuable to the people of the succeeding centuries, throwing light upon medicine of today in its economic, social and clinical aspects.

Single letters may be of the greatest importance, such as the letter of Dr. Zadok Howe, written in 1814 to Dr. Nathaniel Miller on the prospectus of the cancer hospital at Franklin, Massachusetts, and the three letters of Dr. Oliver Wendell Holmes written in 1861 and 1863, relating to the injury received by his son, later Justice Holmes, at Keedysville during the Civil War. Recently the Boston Medical Library has acquired a collection of twenty-two letters of Dr. Howe that throw considerable light upon his personality and character.

Physicians from time to time have collected letters of eminent medical men and have eventually deposited their collections in medical and historical libraries. Dr. Ernest B. Young, of Boston, made such a collection and gave it to the Boston Medical Library before his death in 1923. Dr. Lyman Spalding, of Maine, who lived from 1775 to 1821, was an eminent physician of his time and corresponded with the outstanding physicians of the country. He wrote the first edition of the *Pharmacopoeia of the United States of America*, published in Boston in 1820. His letters and scrapbook and the manuscript of the *Pharmacopoeia* descended to his grand-

## BOOK REVIEWS

*The Treatment of Rheumatism in General Practice* By W S C Copeman, O B E, M A, M D (Cantab), F R C P (London) Fourth edition 8°, cloth, 258 pp Baltimore Williams and Wilkins Company, 1946 \$4.00

This small volume, written for the general practitioner has the virtue of brevity and clarity. It presents the accepted British teaching on rheumatism, which differs somewhat from the American point of view. Although treatment is discussed fully there is too much of a recital of remedies without any critical evaluation of these remedies. The book would have been greatly improved by tables or outlines of treatment that the author advocates. Illustrations would also have added to the teaching value of the work.

*Case Histories in Clinical and Abnormal Psychology* Edited by Arthur Burton 8°, cloth, 680 pp New York and London Harper and Brothers, 1947 \$4.00

This book, although primarily intended as a case book to accompany courses in abnormal psychology, might be of interest to others, such as psychiatrists, general practitioners and certain laymen. The work consists of case histories of varying importance indicative of prevailing psychologic methods in the United States.

Besides the value of the case histories themselves, one gets a vivid example of the usefulness of psychologic testing so far as diagnosis, prognosis and treatment are concerned.

The various papers are an excellent example of scientific reporting, and although each has some special merits, the usefulness of the Rorschach test in depicting various tendencies even when overt signs are absent was of particular interest to the reviewer.

To the general reader this book will undoubtedly demonstrate the importance of the clinical psychologist in evaluating emotional problems—a fact long recognized by psychiatrists.

*Hormones and Behavior: A survey of interrelationships between endocrine secretions and patterns of overt response* By Frank A. Beach With a foreword by Earl T. Engle 8°, cloth, 368 pp New York Paul B. Hoeber, Incorporated, 1948 \$6.50

This work is a detailed, encyclopedic account of the problems concerning the interrelation of hormones and overt behavior. The author has gone to considerable lengths to include a great number of experimental data and has compiled a volume that may be considered unique of its kind. He has included most of the important work done on this subject and has presented it in a well systematized manner. Because of the peculiar nature of the studies, the author has limited himself in great part to a recitation of the known facts and has only attempted to draw general conclusions therefrom.

The major interest of this work is for those who are especially concerned with experimental approach to the problem of hormonal influence on behavior; however, it can be classed among books that will always be of value in any library as a reference work for anyone concerned with behavior in general.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Interesting and Useful Medical Statistics* Edited by William H. Kupper, M D 8°, cloth, 528 pp Dubuque, Iowa William C. Brown Company, 1948 \$6.50

In this unusual book the compiler has presented numerous statistical tables on morbidity and mortality, on the incidence of symptoms, signs, results of treatment of disease and on miscellaneous subjects of medical interest, such as absen-

teism, atomic bomb victims, contraception, dicumarol, drivers, farm and Fourth of July accidents, life expectation, male climacteric, medical education, Negro physicians, smoking, state hoards, UNRRA personnel and weights of men. The tables have been selected from the literature of the past ten years and comprise two hundred and twenty-five topics arranged alphabetically. Full acknowledgment is given to the original publisher. The volume is recommended as an essential reference tool for all medical and general libraries.

*Epilepsy: Proceedings of the Association held jointly with the International League against Epilepsy, December 13 and 14 1946, New York* 8°, cloth, 654 pp, with 167 illustrations and 56 tables Baltimore Williams and Wilkins Company 1947 \$12.00

This volume comprises the twenty-sixth of the *Research Publications of the Association for Research in Nervous and Mental Disease*. Eighty-two persons have contributed to the volume, comprising forty-five papers. The text is divided into seven parts: historical, heredity and pathology, experimental studies, electroencephalography, medical treatment, war and epilepsy, and psychological-social. A good index concludes the text. The publishing is excellent. The book should be in all medical libraries and in the collections of all physicians interested in the subject.

*Physical Treatment of Injuries of the Brain and Allied Nervous Disorders* By K. M. Hern, M C S P, diplomate of Liverpool Physical Training College, in charge of physiotherapy, Department of Military Hospital for Head Injuries Oxford. With a foreword by Air Vice-Marshal Sir Charles P. Symonds, K B E, C B, D M, F R C P 8°, cloth, 96 pp with 83 illustrations Baltimore Williams and Wilkins Company, 1947 \$4.00

This monograph describes the method of treatment employed in the Military Hospital for Head Injuries, Oxford, England. In this method the patient and physiotherapist co-operate. The monograph is well printed and should prove useful to all persons interested in the subject.

*Noah Webster: Letters on yellow fever addressed to Dr. William Currie* With an introductory essay by Benjamin Spector M D 8°, paper, 110 pp, with one portrait Baltimore Johns Hopkins Press, 1947 \$2.00 Supplements to the *Bulletin of the History of Medicine*

Dr. Spector in this monograph has made a noteworthy contribution to American medical history. Noah Webster, generally thought of as a lexicographer, was an epidemiologist of no mean stature and the author of a two-volume treatise on epidemic and pestilential diseases published at Hartford in 1799. Dr. William Currie was a highly respected physician of Philadelphia. He became interested in yellow fever prevalent in his city in 1797 and wrote a series of letters to Benjamin Wyncoop that were published in a local newspaper. The series of twenty-five letters by Webster were addressed to Dr. Currie and likewise published in a newspaper, the *Commercial Advertiser*, New York, during the months of October to December, 1797. In his introductory essay Dr. Spector discusses Webster's contribution to American medical thought and progress and analyzes his work on infectious diseases. A table of contents summarizes the various letters. The monograph is well published in every way. An index, although difficult to compile, would have been a valuable addition to the text. The volume is recommended for all medical and general history collections.

*Identification of Tumors: Essential gross and microscopic pathologic features systematically arranged for easier identification* By N. Chandler Foot, M D, professor of surgical pathology, Cornell University Medical College and surgical pathologist to New York Hospital 8°, cloth, 397 pp, with 241 illustrations and 26 tables Philadelphia J. B. Lippincott Company, 1948 \$6.00

In this volume Dr. Foot has presented a guide to the identification of tumors, malignant and benign, illustrated with photomicrographs. The text is divided into two parts: neo-

Oklahoma City, is also reported from the same source

Other medical surveys under similar federal and American Medical Association auspices have been completed in Alaska and on Indian reservations of the Northwest, the *Washington Report on the Medical Sciences* announces. Another is planned for Puerto Rico. Since the incidence of tuberculosis among Alaskan natives is recorded as sixteen times as high as the rate for the continental United States, it is comforting to know that the continent's oldest inhabitants currently receive more tangible evidence of their adopted country's esteem than souvenir canes.

\*Four-year median.  
†Six year median.

#### COMMENT

Diseases with an incidence above the seven-year median were chicken pox, diphtheria, German measles, measles, mumps, lobar pneumonia and undulant fever.

Diseases with an incidence below the seven-year median were bacillary dysentery, meningitis, poliomyelitis, scarlet fever and whooping cough.

Mumps was again at the highest level since it was made reportable in 1916. Poliomyelitis was at the lowest since 1942.

There is still too much diphtheria. The majority of the cases were in unimmunized persons. Some were in persons who had failed to have booster doses.

#### GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Actinomycosis was reported from Everett, 1, total, 1.  
Diphtheria was reported from Arlington, 4, Athol, 1, Boston, 19, Brookline, 1, Cambridge, 1, Lawrence, 1, Montague, 1, total, 28.

Dysentery, bacillary, was reported from Boston, 1, Fitchburg, 1, Holyoke, 1, Lowell, 3, Worcester, 2, Wrentham, 1, total, 9.

Encephalitis, infectious, was reported from Worcester, 1, total, 2.

Lymphocytic choriomeningitis was reported from Cambridge, 1, Danvers, 1, Fitchburg, 7, total, 9.

Malaria was reported from Swansea, 1, total, 1.

Meningitis meningococcal, was reported from Boston, 1, Brookline, 1, Cambridge, 1, Lynn, 1, Quincy, 1, total, 5.

Meningitis, Pfeiffer bacillus, was reported from Holyoke, 1, South Hadley, 1, total, 2.

Meningitis, pneumococcal, was reported from Boston, 1, total, 1.

Meningitis, streptococcal, was reported from Groton, 1, total, 1.

Meningitis, undetermined, was reported from Ashburnham, 1, Brockton, 1, Cambridge, 1, Chicopee, 1, Plainville, 1, Stoughton, 1, total, 6.

Poliomyelitis was reported from Agawam, 1, Arlington, 1, Barnstable, 1, Belmont, 1, Boston, 6, Cambridge, 2, Carver, 1, Chicopee, 1, Dartmouth, 1, Everett, 2, Framingham, 1, Hinsdale, 1, Leominster, 1, Lexington, 1, Mansfield, 1, Marblehead, 1, Marlboro, 1, Millbury, 1, New Bedford, 1, Newton, 2, Northampton, 1, Pittsfield, 1, Princeton, 1, Rockport, 1, Salem, 1, Salisbury, 1, Springfield, 9, Walpole, 1, Watertown, 2, West Boylston, 2, West Springfield, 7, Woburn, 1, Worcester, 4, total, 55.

Salmonellosis was reported from Beverly, 1, Worcester, 1, total, 2.

Septic sore throat was reported from Boston, 2, Chelsea, 1, Newton, 1, total, 4.

Trichinosis was reported from Methuen, 1, Swansea, 1, Watertown, 1, total, 3.

Typhoid fever was reported from Fall River, 1, total, 1.

Undulant fever was reported from Bridgewater, 1, Marblehead, 1, Rehoboth, 1, Templeton, 1, total, 4.

## MISCELLANY

### TRAINED FISH

Scientists at the University of Wisconsin, according to a recent news release, are training fish to smell. Such a course would be considered unnecessary on the Atlantic seaboard—classified with carrying coals to Newcastle.

Actually, the bluntnose minnow, in contradiction to its descriptive name, has been found to have an unusually keen sense of smell. It can detect phenols in water in low concentrations and, with the use of electric shocks to condition its reflex, has been taught to react in an agitated manner when the offending substance is encountered.

### MEDICAL DIRECTOR OF NEW ENGLAND TELEPHONE AND TELEGRAPH COMPANY

Dr. George F. Wilkins, of Brookline, a native of Kinderhook, New York, and a graduate of Holy Cross College and Harvard Medical School, has been appointed medical director of the New England Telephone and Telegraph Company.

### OLD MAN OF THE SEA

If the Federal Security Administration figures on births and longevity are reasonably reliable, 21,500,000 of the nation's population will be sixty-five years of age or over by a century's end, *Insurance Economics Surveys* reports. With a steadily decreasing number of employable citizens the social security burden of the future can be left to the imagination.

### NATIONAL MENTAL HEALTH ACT

In the year since funds were made available under the National Mental Health Act of 1946, Government supported programs have been activated in forty-two states and four territories, according to a report from *Scientific American*. The six remaining states are in process of setting up their programs.

FOURTH ANNUAL SERIES OF INTENSIVE  
POSTGRADUATE COURSES

1	Ocular Pathology	Motility and Orthoptics	January 10-14 1949
2	Psychosurgery		January 24-28 1949
3	Psychiatry	January 31-February 11 1949	
4	Therapeutics	January 31-February 4 1949	
5	Gastrointestinal Problems in Pediatrics	February 7-11 1949	
6	Obstetrics	February 14-18 1949	
7	Gynecology	February 21-25 1949	
8	Anesthesiology	February 28-March 4 1949	
9	Surgical Physiology	March 7-11 1949	
10	Abdominal Surgery	March 14-25 1949	
11	Bone and Joint Surgery	March 28-April 1 1949	
12	Neoplastic Diseases	April 4-8 1949	
13	Metabolic Diseases	April 11-15 1949	
14	Thoracic Diseases	April 18-22 1949	
15	Cardiovascular Diseases	April 25-May 6 1949	
16	Gastroenterology	May 9-13 1949	

By appropriate combinations of the above the following longer courses can be arranged:  
For the Psychiatrist (Courses No. 2, 3) January 24-February 11 1949  
For the General Physician (Courses No. 4, 5, 6) January 31-February 18 1949

For the Obstetrician (Courses No. 6, 7) February 14-25 1949  
For the Surgeon (Courses No. 7, 8, 9, 10, 11, 12) February 21-April 8 1949

For the Internist (Courses No. 13, 14, 15, 16) April 11-May 13 1949  
Other combinations can also be arranged.

A Distinguished Guest Faculty Will Supplement the Local Staff  
Registration in each course is limited.

Hotel accommodations are available.  
Veterans can use their benefits under the G. I. Bill.

## CHARLES B. TOWNS HOSPITAL

Established 1901

FOR ALCOHOLISM, NARCOTIC  
AND BARBITURATE ADDICTIONS

Exclusively

THE TOWNS TREATMENT is a medical and psychiatric procedure.

Withdrawal of narcotics, either opiates or synthetics, is by gradual reduction and specific medication.

After 47 years, this treatment is generally accepted as standard.

Physicians and psychiatrists in residence. Trained nursing, physio- and hydrotherapy staff.

Patients are assured of complete privacy if desired.

Length and cost of treatment are pre-determined.

Advantageously situated facing Central Park. Solarium and recreation roof. Excellent cuisine and service.

Literature on Request

Member American Hospital Association  
Our ad also in J. A. M. A. and other leading medical journals

plasms of general distribution, and neoplasms of special systems and organs, including a chapter on the ear and eye. The text is concluded with two special chapters on the technical methods of value in the diagnosis of tumors and a tabular locator for tentative identification of neoplasms. A good index concludes the volume. The illustrations are excellent, clear and well defined. The type is large and clear, and the printing well done. The book should prove valuable to students, surgeons and physicians.

*Handbook of Treatment and Medical Formulary.* By Charles M. Gruber, M.D., professor of pharmacology, Jefferson Medical College, Philadelphia 8<sup>th</sup>, cloth, 585 pp. Philadelphia: F. A. Davis Company, 1948. \$7.00.

Dr. Gruber has written this manual for the general practitioner and under each disease gives condensed methods of treatment and dosages in metric and apothecaries' measures, of the recommended remedies. The material is arranged alphabetically. A valuable appendix of sixty pages lists important drugs, galenic preparations and chemicals with average doses. There is a good index. The manual should prove valuable to the practicing physician as a quick reference source.

*Synopsis of Pediatrics.* By John Zahorsky, M.D., professor of pediatrics and director, Department of Pediatrics, St. Louis University of Medicine, and pediatrician-in-chief to the St. Mary's Group Hospitals. Assisted by T. S. Zahorsky, M.D., senior instructor in pediatrics, St. Louis University School of Medicine, and assistant pediatrician to the St. Mary's Group of Hospitals. Fifth edition. 12<sup>th</sup>, cloth, 449 pp., with 158 text illustrations and 9 color plates. St. Louis: C. V. Mosby Company, 1948. \$5.50.

This edition of a standard manual, intended primarily for students, first published in 1934, has been thoroughly revised and enlarged to some extent. Material on the newer drugs has been incorporated in the text. A good index concludes the volume. The manual should prove useful to students and general practitioners. The publishing is excellent, although the type is of a small size necessitated by the size of the volume and the amount of text.

## NOTICES

### HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society will be held in the amphitheater of Building D, Harvard Medical School on Tuesday, November 9, at 8 p.m. The Department of Biological Chemistry, Harvard Medical School, will present the following program:

The Production of Radioactive Cystine by Direct Bombardment in the Pile. Eric G. Ball, Arthur K. Solomon and Octavia Cooper.

Ascorbic Acid and the Biologic Action of Adrenal Cortical Hormones. Ralph W. McKee, Theodore S. Cobbe, Jr., and Quentin M. Geiman.

Metabolism of  $C^{14}$ -Labeled Glucose by the Rat Diaphragm in Vitro. Claude A. Villee.

Isotopic Studies of the Origins of Glycogen Carbons. A. Baird Hastings and Yale J. Topper.

Localization of Cerebral Tumors Employing  $P^{32}$ . Bertram Selzerstone, Arthur K. Solomon and William H. Sweet.

Subsequent meetings will be held on December 14, January 11, February 8, March 8, April 12 and May 10.

### NEW ENGLAND CONFERENCE OF INDUSTRIAL PHYSICIANS AND SURGEONS

The yearly dinner meeting, with election of officers, of the New England Conference of Industrial Physicians and Surgeons will be held at the University Club, Boston, on November 10, at 6:00 p.m. Colonel W. C. Knott, M.C., U.S.A., will speak after the dinner on the subject "What the United States Army is doing in Industrial Medical Work."

### AMERICAN ACADEMY OF GENERAL PRACTICE

The first annual scientific assembly of the American Academy of General Practice will be held at the Netherlands Plaza Hotel, Cincinnati, Ohio, March 7 to 9. The program will include essays by eighteen outstanding medical teachers, a dinner for secretaries and presidents of constituent state chapters and a banquet for members and their wives and guests.

Nonmembers of the Academy may attend the assembly as guests on payment of a registration fee of \$5.00 (only doctors of medicine may register). There is no registration fee for members. Banquet tickets will be sold at \$5.00 a plate.

Members wishing to make hotel reservations may apply to the chairman, Sub-Committee on Hotels, American Academy of General Practice, Dixie Terminal Building, Cincinnati 2, Ohio.

### AMERICAN ACADEMY OF DERMATOLOGY AND SYPHILOLOGY

The seventh annual meeting of the American Academy of Dermatology and Syphilology will be held in Chicago December 4 through 9.

The principal sessions will be held at the Palmer House, with special courses in histopathology and mycology scheduled for Saturday and Sunday, December 4 and 5, at the Medical Schools of the University of Illinois and Northwestern University. As in the past two years, teaching clinics will be held on the afternoons of Monday, Tuesday and Wednesday, December 6, 7 and 8. A new feature this year consists of informal discussion groups, which will be held at noon and 5:00 p.m.

Extensive scientific and technical exhibits will be set up. Dr. Samuel M. Bluefarb is chairman of the committee on scientific exhibits, and Dr. Clyde L. Cummer is in charge of the technical exhibits.

Special courses in histopathology, mycology, x-ray and radium therapy, mucous-membrane lesions, bacteriology of the skin, industrial dermatoses, specific granulomas and dermatoscleroses will be held under leaders in these various fields.

Special lectures will be given on "Certain Aspects of Blood Dyscrasias of Special Interest to Dermatologists," by Dr. Cyrus C. Sturgis, chairman, Department of Internal Medicine, Medical School, University of Michigan; "The Relation of Endocrines to Cutaneous Diseases," by Dr. Arthur A. Hellbaum, professor of pharmacology, School of Medicine, University of Oklahoma; and Dr. E. C. Keaty, research associate of pharmacology and dermatology, School of Medicine, University of Oklahoma.

## THE RELATION OF VASCULAR DISEASE TO THE HYPERTENSIVE STATE\*

### II The Adequacy of the Renal Biopsy as Determined from a Study of 500 Patients

BENJAMIN CASTLEMAN, M.D.,† AND REGINALD H. SMITHWICK, M.D.‡

BOSTON

IN APRIL, 1943, the anatomic findings observed in renal biopsies removed from 100 hypertensive patients subjected to bilateral dorsolumbar sympathectomy were reported.<sup>1</sup> The biopsies were graded according to the severity of the vascular disease without knowledge of any clinical data about the patient, and it was found that there were enough differences in the degree of vascular disease to classify the group into five grades of advancing severity (Grades 0, 1, 2, 3 and 4). In this first series 7 per cent of cases were Grade 0, 21 per cent Grade 1, and 25 per cent Grade 2—that is, 28 per cent and possibly 53 per cent of the cases showed renal vascular systems so slightly damaged that it seemed unlikely that the blood flow could have been embarrassed sufficiently to be the one factor responsible for the hypertension. We therefore concluded “that in many of these cases and probably others the hypertensive state antedated the renal vascular lesions, which once established, probably aggravated the hypertension.”

Since the publication of this paper, those who believe that renal vascular disease antedates the hypertensive state have objected that a small biopsy is not an adequate sample of the entire kidney and that no definite conclusions should be drawn from these biopsies.<sup>2</sup> We admit that in some cases the biopsy may not have been truly representative of the entire kidney, although an attempt was made to select a region that seemed on gross inspection an accurate sample. It is true that the biopsies are small, averaging 6 by 5 by 4 mm, but each microscopical section contains about fifty cross-sections of arterioles and small arteries. Furthermore, although vascular disease may be segmental in the large vessels and although not every arteriole is necessarily involved in kidneys removed

at autopsy from hypertensive patients, arteriolar disease, when present in a kidney, is by and large a generalized process. It is perhaps possible in a small series of cases to strike a biopsy that is not an adequate sample, but it does not seem likely that this could have occurred in a series of 500 patients, which forms the basis for this report.

Table 1 shows the distribution of the grades of renal vascular disease in these 500 patients. The percentage of cases of Grade 0 and Grade 1 was a

TABLE 1 *Distribution of Renal-Biopsy Grades*

GRADE	NO OF CASES	PERCENTAGE
0	21	4.2
1	96	19.2
2	111	22.2
3	218	43.6
4	54	10.8
Total	500	

little smaller than that in the first series of 100 patients—23.4 as compared with 28.0 per cent, and 45.6 per cent if one includes the Grade 2 cases, which really have very little arteriolar disease. Thus, 45 per cent of this series of 500 patients had so little anatomic change in their vascular systems that the blood flow through the kidneys could not conceivably have been reduced sufficiently to represent the sole factor in the production of the hypertension.

Added confirmatory evidence for the accuracy of our grading and for the adequacy of the biopsy is the fact that in 100 cases a biopsy was taken from each kidney and that in the large majority the grade of vascular disease was the same on both sides. In only 5 cases was there a difference of two grades, in 20, there was a difference of one grade, and in the rest (75 per cent), the grades were the same. These findings are in keeping with the known bilateral character of the renal changes when they occur, and also with split-clearance studies as carried out by Chasis and Redish.<sup>3</sup> These authors have

## Old Way...

### CURING RICKETS in the CLEFT of an ASH TREE

FOR many centuries,—and apparently down to the present time, even in this country—ricketic children have been passed through a cleft ash tree to cure them of their rickets, and thenceforth a sympathetic relationship was supposed to exist between them and the tree.

Frazer\* states that the ordinary mode of effecting the cure is to split a young ash sapling longitudinally for a few feet and pass the child, naked, either three times or three times three through the fissure at sunrise. In the West of England, it is said the passage must be "against the sun." As soon as the ceremony is performed, the tree is bound tightly up and the fissure plastered over with mud or clay. The belief is that just as the cleft in the tree will be healed, so the child's body will be healed, but that if the rift in the tree remains open, the deformity in the child will remain, too, and if the tree were to die, the death of the child would surely follow.

\*Frazer J. G.: The Golden Bough, vol. 1, New York, Macmillan & Co., 1923

It is ironical that the practice of attempting to cure rickets by holding the child in the cleft of an ash tree was associated with the rising of the sun, the light of which we now know is in itself one of Nature's specifics.

## New Way...

### Preventing and Curing Rickets with OLEUM PERCOMORPHUM

NOWADAYS, the physician has at his command, Mead's Oleum Percomorphum, a Council-Accepted vitamin D product which actually prevents and cures rickets, when given in proper dosage.

Like other specifics for other diseases, larger dosage may be required for extreme cases. It is safe to say that when used in the indicated dosage, Mead's Oleum Percomorphum is a specific in almost all cases of rickets, regardless of

degree and duration. Mead's Oleum Percomorphum because of its high vitamins A and D content is also useful in deficiency conditions such as tetany, osteomalacia and xerophthalmia.

\* \* \*

#### COUNCIL-ACCEPTED

Oleum Percomorphum With Other Fish Liver Oils and Viosterol Contains 60,000 vitamin A units and 8,500 vitamin D units per gram and is supplied in 10 c.c. and 50 c.c. bottles; and in bottles containing 50 and 250 capsules.

MEAD JOHNSON & COMPANY, Evansville, Indiana, U S A.

WELLESLE

group, those with Grade 2 and 3 eye-ground changes, all grades of renal vascular change were present

Is there any correlation between the age of the patient and the degree of renal vascular change? Table 4 shows the age distribution of the 500 patients. The great bulk, almost 75 per cent, of them were between thirty and fifty. There were, however, 61 patients under thirty (Table 5) and it is interesting to note that 38 per cent had Grade 0 or 1 biopsies and if the changes in Grade 2 are included, 62.5 per cent of the younger patients had minimal vascular disease. These figures are even more significant when they are compared with the cor-

adequate samples of their respective kidneys. The highlights of this evidence are as follows: First, approximately the same percentage of cases for each biopsy grade was present in a series of 500 cases as in the first series of 100 cases. Secondly, in 100 patients from whom biopsies were taken from both right and

TABLE 4 Age Distribution

AGE	NO OF PATIENTS
10-19	8

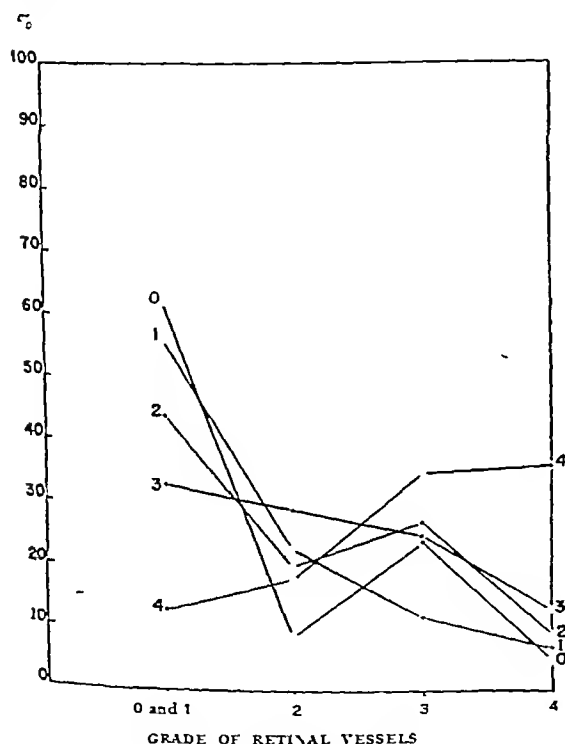

FIGURE 2. Correlation of Renal-Biopsy Grades with Retinal-Vessel Changes

responding percentage among all age groups—namely 23.4 and 45.6 per cent (Table 1). It is very difficult, if not impossible, to know when a patient develops hypertension. Many have had their disease for years before it is discovered. Thus a patient of forty-five may well have had hypertension for ten years or more before it was first discovered, but a patient in the twenties, by the mere limitation of his age, has probably had it for a relatively short period. Assuming that hypertension is primary and renal arteriosclerosis secondary, a much milder degree of vascular change is expected in the younger group, and this is what was found.

#### SUMMARY AND CONCLUSIONS

We believe that the material presented affords fairly conclusive evidence that the biopsies are

left kidneys the grade of vascular disease was the same in 75 per cent of cases, and in only 5 per cent was there a difference of two grades (thus, in 95 per cent, the degree of vascular disease for all practical purposes was identical on both sides). Thirdly, in this group of 100 double biopsies 40 patients had minimal or no arteriolar disease on each side. Fourthly, there was good correlation between the biopsy grades and renal function as measured by the phenolsulfonephthalein test in the entire series of 500 patients and in 20 patients when compared with renal plasma-flow values (previous study). Fifthly, there was fairly good correlation between the biopsy grades and the retinal-vessel changes when applied to the lowest and highest grades

TABLE 5 Distribution of Renal-Biopsy Grades among Patients Under Twenty-Nine Years of Age

GRADE	NO OF CASES	PERCENTAGE
0	5	8
1	18	30.0
2	18	29.5
3	15	24.5
4	5	8.0
Total	61	

Finally, of the 61 patients under thirty years of age 62.5 per cent had minimal or no renal vascular disease.

For these reasons we believe that the biopsy material provides an adequate basis for conclusions regarding the degree of arteriolar disease in hypertensive patients. To repeat, 23.4 per cent of the biopsies were placed in Grade 0 or 1 and 22.5 per cent in Grade 2. Thus, 45.6 per cent of a series of 500 cases had minimal or no vascular narrowing. Since no one had objected to the accuracy of the observations in the biopsies it must be concluded as in

shown that the decrease in the rate of glomerular filtration and effective renal blood flow in hypertensive patients is shared equally by the kidneys. "These results indicate that the destruction of renal parenchyma progresses equally in the two kidneys in hypertensive disease." Forty of the 100 patients with double biopsies had minimal or no vascular disease on each side. This large percentage of Grade 0 and 1 vascular disease is probably due to the fact that as the years have gone by we have gradually come to see hypertension in its earlier stages and in younger patients. It seems to us that this finding of minimal vascular change in 40 per cent of this series is quite significant because the chances of missing real vascular disease twice are very unlikely.

Although it is fairly well established that the majority of hypertensive patients do not have renal impairment as measured by the phenolsulfonephthalein test, the finding that those with the more severe vascular disease in their renal biopsies had a decreased renal function and those with minimal vascular disease good renal function would

TABLE 2 Correlation of Renal Biopsies with Renal Function

GRADE	NO OF CASES	RENAL FUNCTION		
		NORMAL	MODERATE REDUCTION	SHARP REDUCTION
0	21	84.6% {	20	0

4	54		25	28
Totals	500	316 (63.2%)	120 (24.0%)	64 (12.8%)

provide additional support for the adequacy and accuracy of these biopsies. Renal function was measured by the phenolsulfonephthalein test in this series (Table 2). Sixty-four patients, or 12.8 per cent, had poor renal function, and when these cases are divided into their respective renal-biopsy grades it is quite obvious that most of them represented definite vascular disease. Ninety-two per cent had either Grade 3 or Grade 4 biopsies. At the other end of the scale, those with Grade 0 or Grade 1 renal biopsies, there were 117 patients, 84 per cent of whom had excellent renal function. When this correlation is charted (Fig 1), the distribution of normal renal function among the renal biopsies in the first 100 cases was confirmed in the larger series of 500 cases.

Often, the severity of a patient's hypertension is based on the appearance of the eye-ground changes. We therefore believed that it would be interesting to compare the vascular changes in the retina with those in the renal biopsies. Table 3 shows that there is some correlation, especially in the very low and very high grades. For example,

in 48 of the 66 (about 70 per cent) of the patients with Grade 4 retinal changes — changes that most clinicians consider diagnostic of malignant hypertension — renal biopsy revealed Grade 3 or 4 vascular disease. Likewise, about two thirds of the patients with Grade 4 renal biopsies had Grade 3

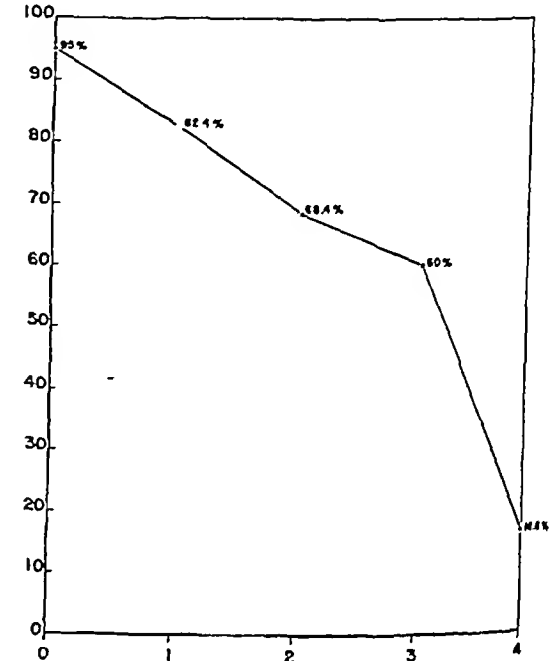

FIGURE 1 Distribution of Normal Renal Function among the Renal Biopsies

or 4 retinal change (37 out of 54). In the cases with Grade 0 or 1 renal biopsies, 78 per cent (91 out of 117) showed Grade 0, 1 or 2 retinal change. Although there were exceptions in all groups, in the Grade 2 and 3 renal biopsies all grades of retinal changes were rather well represented. This may

TABLE 3 Correlation of Renal Biopsies with Retinal Vessel Changes

GRADE	NO OF CASES	RETINAL VESSEL CHANGE				
		GRADE 0	GRADE 1	GRADE 2	GRADE 3	GRADE 4

be better visualized in Figure 2, in which the percentages of each of the retinal-vessel grades are calculated for each biopsy made. It is apparent that there is a definite correlation of the cases with Grade 0 and 1 eye grounds and those with Grade 4 eye grounds with the renal biopsies. In the middle

group, those with Grade 2 and 3 eye-ground changes, all grades of renal vascular change were present

Is there any correlation between the age of the patient and the degree of renal vascular change? Table 4 shows the age distribution of the 500 patients. The great bulk, almost 75 per cent, of them were between thirty and fifty. There were, however, 61 patients under thirty (Table 5), and it is interesting to note that 38 per cent had Grade 0 or 1 biopsies and if the changes in Grade 2 are included, 62.5 per cent of the younger patients had minimal vascular disease. These figures are even more significant when they are compared with the cor-

adequate samples of their respective kidneys. The highlights of this evidence are as follows: First, approximately the same percentage of cases for each biopsy grade was present in a series of 500 cases as in the first series of 100 cases. Secondly, in 100 patients from whom biopsies were taken from both right and

responding percentage among all age groups — namely 23.4 and 45.6 per cent (Table 1). It is very difficult, if not impossible, to know when a patient develops hypertension. Many have had their disease for years before it is discovered. Thus a patient of forty-five may well have had hypertension for ten years or more before it was first discovered, but a patient in the twenties, by the mere limitation of his age, has probably had it for a relatively short period. Assuming that hypertension is primary and renal arteriosclerosis secondary, a much milder degree of vascular change is expected in the younger group, and this is what was found.

SUMMARY AND CONCLUSIONS

We believe that the material presented affords fairly conclusive evidence that the biopsies are

left kidneys the grade of vascular disease was the same in 75 per cent of cases, and in only 5 per cent was there a difference of two grades (thus, in 95 per cent, the degree of vascular disease for all practical purposes was identical on both sides). Thirdly, in this group of 100 double biopsies, 40 patients had minimal or no arteriolar disease on each side. Fourthly, there was good correlation between the biopsy grades and renal function as measured by the phenolsulfonephthalein test in the entire series of 500 patients and in 20 patients when compared with renal plasma-flow values (previous study). Fifthly, there was fairly good correlation between the biopsy grades and the retinal-vessel changes when applied to the lowest and highest grades.

TABLE 5 Distribution of Renal Biopsy Grades among Patients Ten to Twenty-Nine Years of Age

Grade	No of Cases	Percentage
0	5	8
1	18	30.0
2	15	24.5
3	15	24.5
4	8	13.0
Total	61	

Finally, of the 61 patients under thirty years of age 62.5 per cent had minimal or no renal vascular disease.

For these reasons we believe that the biopsy material provides an adequate basis for conclusions regarding the degree of arteriolar disease in hypertensive patients. To repeat, 23.4 per cent of the biopsies were placed in Grade 0 or 1, and 22.5 per cent in Grade 2. Thus, 45.6 per cent of a series of 500 cases had minimal or no vascular narrowing. Since no one had objected to the accuracy of the observations in the biopsies it must be concluded as in

our previous report, that hypertension frequently exists in man without evidence of renal vascular disease or with insufficient evidence to explain the elevated blood pressure. Therefore, some other functional factor or factors that are primarily responsible for the hypertensive state and precede the appearance of renal vascular disease must exist in many cases.

## DOUBLE UTERUS WITH HORN MENSTRUATING INTO THE ABDOMEN

JOHN B. VERNAGLIA, M.D.\*

MEDFORD, MASSACHUSETTS

A review of the literature has disclosed no case similar to the one reported below, which is that of a completely separated double uterus, both halves well developed, in which one uterus did not communicate with the vagina and menstruated into the abdomen. The situation was recognized at operation at the time of the patient's third menstrual period, and a hemi-hysterectomy was done. Later, the patient became pregnant and was delivered of a living child by cesarean section.

Congenital anomalies of the uterus are interesting but potentially serious conditions that warrant the careful consideration of every surgeon, gynecologist and obstetrician. They can cause dysmenorrhea, sterility, inflamed appendages, miscarriage, abnormal presentations, difficult or impossible delivery, uterine rupture, puerperal sepsis, placenta previa, retained placenta, post-partum hemorrhage and subinvolution. When there is atresia in the vagina or cervix, one may find, in addition to dysmenorrhea, hematocolpos, hematometra and hematosalpinx.

Embryologically the uterus and vagina are formed by the fusion of the two müllerian ducts in their distal or caudal two thirds. The cephalic third of each duct remains unfused and forms the fallopian tube on each side. These ducts appear during the sixth week of embryonic life, close to the more developed wolffian ducts. Their caudal segments move medially and become fused from below upward during the twelfth to the fourteenth week and form one tube, the uterus, cervix and vagina. Lack of complete fusion and disappearance of the intervening septum, at any point from below upward or throughout the length of the two ducts, explains most of the anomalies observed, the rudimentary development of one duct or of the cervical canal of one side accounts for the remainder. Nonfusion occurs normally in lower mammals, so that Blair-Bell suggests the use of the term "atavism" in preference to "malformation,"

because an anomalous uterus conforms exactly with that of one of the lower orders. Marsupials or didelphys, like the kangaroo and the opossum, have double uteri and lateral vaginas with a central vaginal pouch. The rodents (rabbits, squirrels, rats, guinea pigs, porcupines and gophers) have double uteri with separate cervixes and vaginas in the lower forms, and double uteri with a single cervix and a single vagina in the higher forms. The carnivora (cats, dogs, bears, weasels, raccoons and seals) have uterine bodies that are fused in their lower parts to form a bicornuate uterus. In primates, such as monkeys, apes and man, the highest form of uterine development, the uterus simplex, is found.

Because of the close association of the müllerian ducts with the wolffian ducts, anomalies of the urinary tract are often found in conjunction with anomalies of the female genital tract, especially the absence of a kidney, more often the right, according to Findley<sup>1</sup> and most authorities. However, Eismayer<sup>2</sup> states that the left kidney is more frequently absent with double uterus. Also, double anus, double bladder, presence of a cloaca and incomplete rotation of the colon (Sweet<sup>3</sup> and Benjamin and Danforth<sup>4</sup>) have been reported.

The various types of uteri are illustrated in Figure 1. A simple classification of malformations of the uterus and the vagina is that of Jarcho,<sup>5</sup> which is a simplification of that of Kaufmann.<sup>6</sup> This classification identifies seven types: uterus didelphys, uterus duplex bicornis bicollis, uterus bicornis unicollis, uterus septus, uterus subseptus, uterus arcuatus or cordiformis, and uterus unicornis. The first can occur with double vulva and should not be called "uterus pseudodidelphys" but rather "uterus didelphys cum vulva duplici," according to Jarcho.<sup>5</sup> A double vagina is present almost always, in the first type and often in the second. An even simpler classification of uterine anomalies, which recognizes only four main types and is much like classifications used by Royster<sup>7</sup> and also by Sichel,<sup>8</sup> is as follows: uterus didelphys

\*Senior visiting surgeon, Cambridge City Hospital and Lawrence Memorial Hospital; consulting surgeon, Symmes Arlington Hospital.

—usually with septate (double) vagina, uterus bicornis including bicornis bicolis (often with septate [double] vagina) and bicornis unicollis, uterus septus, complete and incomplete, and uterus unicornis

The arcuate or cordiform uterus is merely a depression in the fundus of a normal uterus and is hardly worthy of a separate classification, though it may cause complications in pregnancy, labor and the puerperium. This classification is also essentially similar to that of Strassmann.<sup>9</sup>

The most serious complication of all these uterine malformations is the occurrence of pregnancy in a rudimentary or well developed horn that has no communication with, or a deficient cervical canal communicating with, the other uterus or the vagina. Pregnancy may occur in such a uterus by external migration of the spermatozoon or impregnated ovum. Rupture will occur at about four to six months with even more profuse hemorrhage than that from rupture in tubal pregnancy. Death usually occurs ten to fifteen minutes after rupture in about 90 per cent of cases (De Nicola and Petersen<sup>10</sup> — in 88 per cent of cases according to Mundell<sup>11</sup>). The case reported below was such a situation, discovered before pregnancy had occurred. Rarely, the fetus in such a pregnancy dies and becomes mummified. Scott and Forman<sup>12</sup> reported twin fetuses retained in a horn of a bicornuate uterus for twenty years. At operation, a pregnant uterine horn can be distinguished from a tubal pregnancy if the operator identifies the round ligament lateral to the mass. Also, the other uterine horn is found to have a tube and ovary on its lateral side only. In Mulsow's<sup>13</sup> case (1945) rupture of a pregnant rudimentary horn occurred at five months, with death in fifteen minutes. Mulsow, in a review of the literature since 1911, could find reports of only 9 cases of pregnancy in a rudimentary horn. De Nicola and Petersen<sup>10</sup> reported a pregnancy in a rudimentary horn in 1947 and cited a case from India by Waters (1944), which had not been mentioned by Mulsow. Fortunately, an incorrect diagnosis of a tubal pregnancy is usually made and the rudimentary horn is discovered at operation, otherwise the condition is discovered at autopsy. The first recorded case of such a pregnancy is credited to Moriceau and Vassel by Wardlaw and Smith.<sup>14</sup> Uteri with rudimentary horns are unsuspected because they do not have a vaginal septum. Injection of lipiodol followed by x-ray examination (uterosalpingography) will not reveal such a horn. In 1930 Grant and Rose<sup>15</sup> added a case to 6 recorded cases of bicornuate uteri with atresia and hematometra of one horn, the previous cases having been reported by Robinson<sup>16</sup> in 1910, Maclean<sup>17</sup> in 1911, Oliver<sup>18</sup> in 1912, Schwarz<sup>19</sup> in 1921, Nemes<sup>20</sup> in 1921 and Champel<sup>21</sup> in 1921. Several other cases have been reported without pregnancy in such

uteri, the horn having little or no connection with the other uterus or the vagina, and causing hematometra with or without hematosalpinx. No case is recorded in which a well developed horn menstruated into the abdomen under the peritoneum, forming a pseudocyst distended with menstrual blood, as in the case reported below. According to Puddicombe,<sup>22</sup> Kehrer, in 1900, collected 84 cases of pregnancy in rudimentary horns. In 1916 De Lee<sup>23</sup> reported about 100 cases of pregnancy in a rudimen-

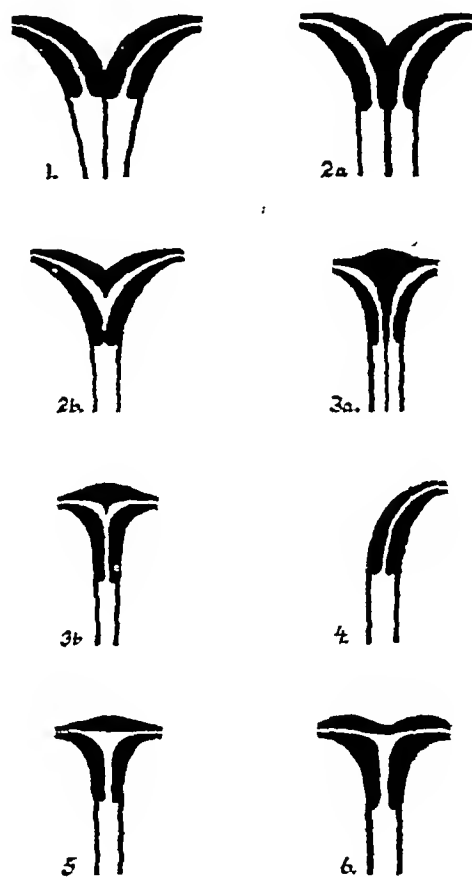

FIGURE 1 Various Types of Uterus

tary horn, indicating that the condition is not extremely rare.

In summary, therefore, the nonfused proximal thirds of the müllerian ducts normally form the two tubes, the fused middle thirds of the two ducts normally the single uterus and cervix, and the normal fusion of the distal thirds of the two ducts the single vagina. Various degrees of failure of fusion or of absorption of the intervening septum produce different types of doubling of the uterus, cervix and vagina. Uterus didelphys is caused by

our previous report, that hypertension frequently exists in man without evidence of renal vascular disease or with insufficient evidence to explain the elevated blood pressure. Therefore, some other functional factor or factors that are primarily responsible for the hypertensive state and precede the appearance of renal vascular disease must exist in many cases.

rudimentary horn is always advisable because of the danger of pregnancy. Whenever possible surgical intervention for uterine anomalies should be conservative. Surgical measures based solely on the presence of an anomaly are seldom justified (Jarcho,<sup>5</sup> Granberry and Faust,<sup>31</sup> Smith,<sup>32</sup> Schauffler,<sup>36</sup> Sweet<sup>2</sup> and Tyler<sup>37</sup>).

### CASE REPORT

E. L. (NH 59904) a 12½-year-old girl, was admitted to the hospital on March 24 1939 because of abdominal pain. The patient had had two normal periods each with moderate pain lasting 4 days. The present period, beginning 4 days before admission and on time, was accompanied by headache and decreased appetite. Three days previously she had complained of cramp-like pains all over the abdomen and had vomited once. There was an urgent desire to defecate, which was not relieved by enemas and a saline cathartic. The pain, the vomiting and the urgency to defecate became more marked. The pain was localized low in the abdomen and became severe and steady. Enemas produced little feces,—mostly thick gray mucus,—and the mother noticed that the enema tip could not be admitted satisfactorily more than 3.5 to 5.0 cm. On the day of admission the mucus contained some dark blood. There were no symptoms referable to the cardiorespiratory, genitourinary or neuromuscular system.

The past history was irrelevant. The patient had been born after a forceps delivery. Infancy and childhood had been normal. She had had measles, chicken pox and whooping cough but no serious illnesses, accidents or operations.

The mother and father were living and well. The patient was the oldest of a family of four children, all of whom were living and well. There were no familial diseases.

Physical examination disclosed a well developed and well nourished girl, who complained of severe pain in the lower abdomen, more marked on the right. The skin was pink, dry and warm. The head, heart and lungs were normal. The abdomen was not distended. No organs were felt, and there were no hernias. Marked tenderness was noted in the lower abdomen without muscle spasm and without rebound tenderness. Rectal examination revealed a tender mass in front of the rectum, 7.5 to 10.0 cm in diameter.

The temperature was 99°F, the pulse 80, and the respirations 22.

Examination of the blood showed a red-cell count of 4,050,000 with a hemoglobin of 82 per cent, and a white-cell count of 10,200, with 63 per cent neutrophils, 25 per cent small and 10 per cent large lymphocytes and 2 per cent eosinophils. Fluoroscopy with a barium enema demonstrated that the colon filled easily to the cecum, with normal regurgitation through the ileocecal valve. There was no tenderness over the cecum, which was movable and apparently not attached to the mass in the pelvis. There was a tender mass in the pelvis displacing the rectum to the left and apparently not attached to the cecum.

The patient was given intravenous saline solution, 50 mg of morphine, and 0.4 mg of atropine.

At operation, under ether anesthesia she was placed in the lithotomy position and catheterized after preparation and draping of the perineum. On specular examination, the cervix was found displaced to the left and forward by a cystic mass. Aspiration of the mass with a needle revealed black, dark blood. The patient was straightened out on the table, the abdomen was prepared and draped and a right lower paramedian incision was made. Exploration revealed no fluid or free blood. The appendix was normal. Behind the bladder rose two uteri separated about 2.5 cm at the lower ends and about 9 cm at the fundi. Each uterus had one round ligament, and one tube and ovary on its lateral side. The right tube was thick distended and congested. Retroperitoneally, anterior to the sacrum was an ovoid cystic bluish mass, 7.5 by 10.0 cm displacing the rectum to the left and the left uterus anteriorly and to the right. Obviously the cervix, found displaced to the left on specular examination, belonged to the left uterus. Pressure on the right uterus increased the tension in the mass confirming the suspicion that this uterus communicated with and not with the vagina. The mass was tapped and the thick bluish blood was obtained as from the tap of the

posterior cul-de-sac. There was no rectovesical ligament running from the bladder to the rectum and sigmoid as frequently occurs with double uterus. It was decided that the right uterus was menstruating under the peritoneum, forming a menstrual pseudocyst. The peritoneum was incised over the front of the lower end of the right uterus reflecting the bladder forward. A right hemi-hysterectomy and salpingectomy was done. The peritoneum was incised over the cystic mass, and it was easily dissected off the sacrum and rectum posteriorly and from the back of the lower part of the left uterus in front without rupturing. Its cavity communicated with the cervical end of the right uterus through a tract about 0.4 cm in diameter. The same thick bluish blood contained in the cyst distended the uterus and tube producing a moderate hematometra and hematosalpinx. The patient made an uneventful recovery and was discharged on the 12th day.

The gross specimen consisted of a thickened tube, 8.7 cm long, and a uterus about 6.2 cm long and 3.7 cm across its widest point. One side was perfectly smooth. The uterus tapered down to a cervix with a canal, 0.4 cm in diameter which communicated with a pear-shaped saccular structure 10.0 cm long and 6.2 cm wide. The uterus, the tube and the saccular structure contained thick old blood. The endometrium was markedly thickened and hemorrhagic.

Microscopical examination showed the tubal wall to be thickened and infiltrated with round cells. Sections of the uterus were not remarkable except that the endometrium was markedly thick and contained tortuous hyperplastic endometrial glands. Sections through the wall of the saccular structure showed it to be composed of fibrous tissue. The inner surface was covered with red cells. In one area the cyst was lined with tissue that had the appearance of endometrium. The adjacent tissue showed some old hemorrhage characterized by the deposit of hematoïdin and hemosiderin. Histologically the tissue was consistent with an endometrial implant. There was no evidence of cancer or tuberculosis.

The diagnoses were bicornuate uterus, hyperplastic endometritis, endometrial implant and chronic salpingitis.

After this episode the patient enjoyed good health except that she had painful periods, and in June, 1944, the right ovary was removed because it had become large, tender and cystic. At the same time the appendix was removed, and several cysts of the left ovary were resected. The left tube was found patent. The patient married in October 1946. She became pregnant and during the last month of pregnancy developed considerable lower abdominal pain with tenderness and tenseness of the uterus. On April 30 1948 3 weeks before term, she also developed some vaginal bleeding. Because of the danger of rupture of the uterus cesarean section was performed\*. At operation the uterus was tense and thin walled. On the front wall of the distended uterus ran five large veins each 0.6 cm in diameter, which converged low on the left side of the uterus. The lower two which lay in the line of the incision were tied off on either side to prevent unnecessary bleeding. A 4½-pound male baby was delivered, and the placenta showed some partial premature separation. Both mother and baby have done well.

### SUMMARY

The subject of uterine anomalies is reviewed with special reference to embryology, classification, etiology, complications and treatment.

A simplified classification is presented.

What is believed to be the first reported case of double uterus with one uterus not connected with a vagina and menstruating into the abdomen retroperitoneally is presented. Hemi-hysterectomy was done and this patient later bore a child.

Pregnancy in the rudimentary horn of a double uterus is stressed as even more dangerous than an ectopic pregnancy and the diagnosis is more difficult.

Conservative surgical treatment is emphasized.

\*The section was performed by Dr. Emilio D. Ermo, of Medford.

complete failure of fusion of the middle thirds of the ducts, resulting in a double uterus and a double cervix. If the intervening septum remains in the distal thirds, there is also a double vagina. Since obliteration of the septum usually occurs from below upward, a double vagina is almost always present with uterus didelphys and often with uterus bicornis bicollis. Uterus bicornis is due to partial failure of fusion of the ducts in the middle thirds. The region of the cervix may or may not fuse, causing a single or a double cervix. With double cervixes the vagina is often double, as stated above. Uterus septus is due to fusion of the middle thirds of the ducts with persistence of the intervening septum, and the vagina may or may not be double, depending upon what happens to the septum in the distal thirds of the ducts.

Theories to explain the factors responsible for failure of proper fusion of the müllerian ducts are variations in the germ plasma itself (von Winkle, quoted by Moench<sup>24</sup>), variations in biochemical environment during the time of development and fusion of the müllerian ducts — this is the likeliest theory in my opinion, errors in timing of arrival of ducts at midline — the left duct usually advances medially faster (Felix<sup>25</sup>) and interferes with development of the right duct (Anderson<sup>26</sup>), accounting for more variations on the right side, the presence of a rectovesical ligament or fold (Kussmaul, cited by Moench<sup>24</sup>), but this may be an associated anomaly rather than the cause, too short round ligaments (Newton<sup>27</sup> and Meyer<sup>28</sup>), too broad a pelvis, preventing union of ducts (Wardlaw and Smith<sup>14</sup> and Schwarz<sup>19</sup>) — this may be an associated condition and not a cause, fetal peritonitis (a very improbable and rare cause), associated disturbances of development of adjacent structures, such as the wolffian ducts and the urinary bladder or intestinal tract, or both (von Winkle, cited by Moench<sup>24</sup>), preventing normal union of the two ducts, distention of the bladder and uterus and fetal peritonitis are ruled out by Felix<sup>29</sup> because these factors must occur after the fusion that forms the uterovaginal canal, Thiersch<sup>30</sup> blamed the greater development and separation of the wolffian bodies as the most plausible cause, Pick<sup>31</sup> blamed tumors, or interference by stray cells of müllerian tissue keeping the ducts apart. Very probably, other causes are involved, and different factors may be responsible in different cases.

Patients with double uterus are more fertile, according to Findley,<sup>1</sup> but have more abortions. They have more transverse and breech presentations, and also have more prolonged labors. They have poorer uterine musculature and more rigid cervixes, and they run the danger of incarceration of the nonpregnant uterus in the pelvis, where it can act as an obstruction to delivery. The nonpregnant complications of double uterus are dysmenorrhea and the so-called retention complications (Sweet<sup>2</sup>),

hematocolpos, hematometra and hematosalpinx, depending upon the site of atresia. In 1926 Findley<sup>1</sup> collected 135 cases of double uterus and advised conservative management of pregnancy. Falls,<sup>32</sup> who stated that anomalies of the female genital tract occur in about 1 per cent of all women, stressed long labors, post-partum hemorrhage and placenta previa in these cases. He also emphasized an important fact, which bears repeating: the bladder is often carried back over the saddle of a bicornuate uterus in the rectovesical ligament, if present, where it can be damaged during cesarean section or hysterectomy. Strassmann,<sup>9</sup> of Berlin, who came to America to discuss Falls's paper in 1928, stressed the frequency of dysmenorrhea and inflamed appendages. He viewed pregnancy in a double uterus with the same apprehension as ectopic pregnancy, advocating emptying of the uterus and operation to form one cavity because of the frequency and danger of abnormal presentations, placenta previa, puerperal sepsis, retained placenta, post-partum hemorrhage, slow or obstructed labor and ruptured uterus. In 1896 Strassmann had first described his operation for conversion of uterus didelphys into a single uterus with a single cavity. At laparotomy, an incision is made running from fundus to fundus along the medial surfaces of the double uteri down into the internal os. Then the posterior cut edges are sutured to each other, as are the anterior edges up to and including the fundi. After closure of the abdomen, the vaginal septum and then the thick cervical septum are divided with a cautery.

In 1916 Rockey<sup>33</sup> reported a method of operation dividing the vaginal and the intrauterine septums, per vaginam, by leaving long clamps on the anterior and posterior margins of the septums for thirty-six hours, at the same time cutting between them with the cautery. He advised placing the patient in marked Trendelenburg position before the clamps are applied to the uterus in case the uteri are bicornuate because of the danger of clamping bowel between them.

Owing to the great variety of anomalies, each case is an individual problem, and no set rules regarding treatment can be formulated. The less the deformity, the less the danger. The average uterus didelphys will deliver quite normally from either side provided the other uterus does not drop down and get in the way, or does not contain a tumor or another pregnancy, as has not infrequently happened. Quite a few cases have been reported of a second pregnancy and subsequent delivery (involving the other uterus) several or more months after pregnancy in, and delivery from, the first uterus. These cases have been cited by some as proving the occurrence of true superfetation, or the presence of two fetuses of different ages, not twins, owing to impregnation of two ova from different periods of ovulation. The removal of a

admitted for the first time complaining of the attacks of abdominal pain. These attacks were aggravated by food and relieved by induced vomiting. At operation a chronically infected gall bladder filled with small stones was removed. The abdomen was explored, but no other disease was noted. Four years prior to admission she first experienced precordial pain and blurred vision during attacks. For the past 4 years she had been greatly incapacitated. The attacks had occurred as frequently as three or four times a day.

Physical examination disclosed a pale, thin woman, who appeared 20 years older than her stated age. There was no orthopnea or dyspnea. The fundi showed marked arteriovenous nicking and thickening of the arteriolar walls, but no papilledema, hemorrhages or exudate. The lungs were clear. The heart did not appear enlarged. Normal sinus rhythm, with occasional extrasystoles, was present. A coarse Grade II apical systolic murmur was heard. Examination

However, it was noted that there was a definite correlation between the daily hypertensive episodes and the symptoms. The paroxysmal attacks of hypertension accompanied by right-sided abdominal pain, precordial pain, headache and profuse diaphoresis seemed characteristic of an adrenalin-

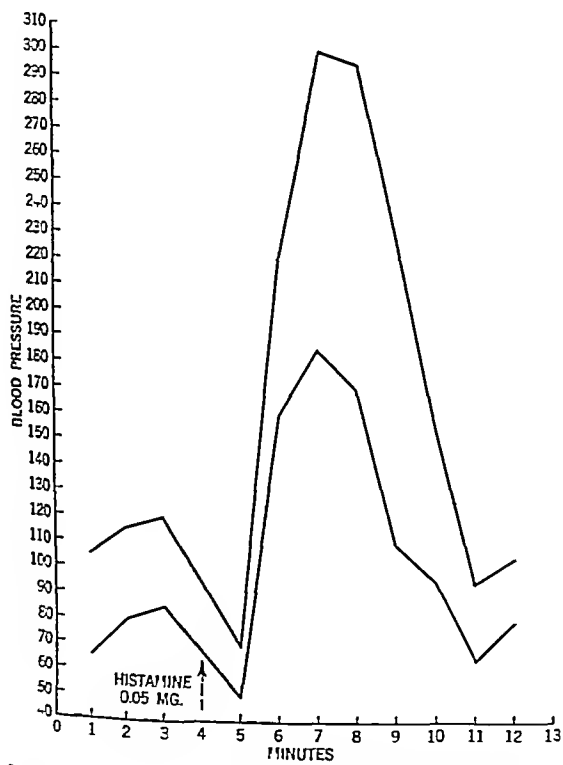

FIGURE 1 Histamine Test Using 0.05 mg of Histamine Base Intravenously

of the abdomen revealed only a well healed upper right rectus scar.

The temperature was 99°F, the pulse 96, and the respirations 18. The blood pressure was 130/100.

On admission and throughout the hospital course the urinalyses, blood counts, sedimentation rates and blood serologic findings were essentially normal. X-ray examination of the chest showed only moderate hypertrophy of the left ventricle of the heart. Repeated electrocardiograms including multiple chest leads, revealed left-axis deviation and inverted T waves in Leads 1, 2 and 4.

A tentative diagnosis of hypertensive cardiovascular disease with coronary insufficiency was made. The patient was placed on nitrites and a rice diet for approximately 3 weeks with no relief of symptoms. During the first 6 weeks it was observed to have a labile hypertension; the blood pressure varying from 250/150 to 130/80. Urine concentration and urea clearance tests were normal. Intravenous pyelograms were normal. Retrograde pyelograms were normal except that the right kidney appeared displaced somewhat laterally and inferiorly.

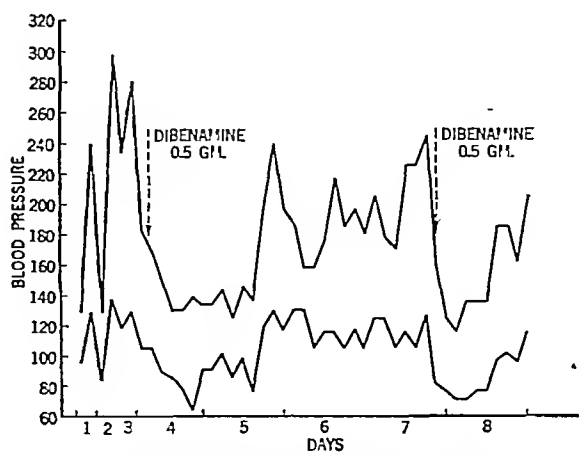

FIGURE 2 Blood-Pressure Recordings, Demonstrating the Effect of Dibenamine Hydrochloride

producing tumor the so-called pheochromocytoma. Accordingly, an intravenous histamine test, described by Roth and Kvale<sup>1</sup> as diagnostic of such a tumor, was performed. The results of this test, using 0.05 mg of histamine base intravenously, are shown in Figure 1. After an initial drop, the blood pressure rose precipitously, associated with precordial and abdominal pain, headache, nausea and diaphoresis.

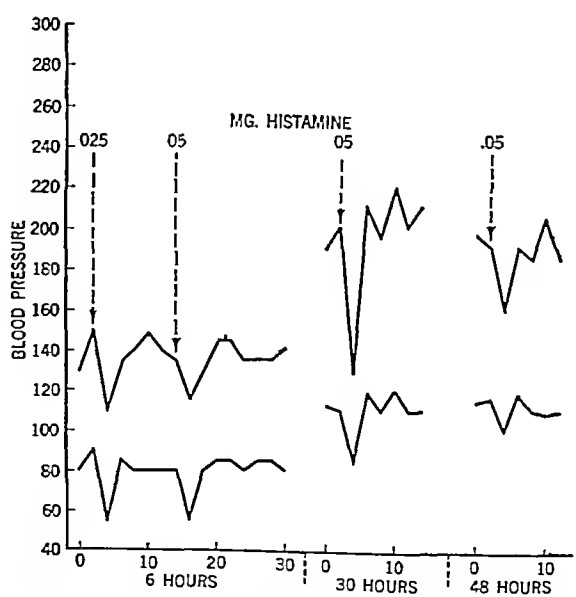

FIGURE 3 Histamine Tests Following the Administration of Dibenamine Hydrochloride

These symptoms cleared as the blood pressure fell. This test was repeated with similar results. A cold pressor test was done and a hyper-reactive blood-pressure response was elicited without the features of the attack previously described. Bilateral perirenal air insufflation with the con-

## THE USE OF DIBENAMINE IN PHEOCHROMOCYTOMA\*

## Report of a Case

HAROLD C SPEAR, M D,† AND DWIGHT GRISWOLD, M D‡

NEW YORK CITY

THE adrenolytic drug dibenamine hydrochloride (dibenzyl-beta-chlorethyl amine hydrochloride)§ is presented as a diagnostic aid when the presence of a pheochromocytoma is suspected and as a therapeutic agent once the diagnosis is confirmed.

The preoperative diagnosis of a pheochromocytoma is based on the clinical picture, retrograde pyelograms and perirenal air studies. But none of these criteria are specific. In the following case dibenamine apparently blocked the effects of a pheochromocytoma by its adrenolytic action. Thus, the drug affords a more specific test in the diagnosis of a pheochromocytoma.

## METHOD OF ADMINISTRATION

The patient was given an intravenous infusion of dibenamine hydrochloride. The dosage was

\*From the Department of Medicine, St. Luke's Hospital.

†Intern in surgery, Grace-New Haven Community Hospital, New Haven, Connecticut; formerly intern in surgery, St. Luke's Hospital.

70 mg per kilogram of body weight. This was diluted in 300 cc of 5 per cent glucose in physiologic saline solution. For its administration a Y-infusion set was used. One arm was attached to the bottle containing the dibenamine, and the other to one containing 5 per cent glucose in physiologic saline solution. The infusion was started with the glucose in saline solution, and then was switched to the dibenamine, which was administered over a period of one hour to lessen the possibility of toxic reactions.

## CASE REPORT

On September 11, 1947, M P, a 51-year-old woman, was admitted to the hospital for the second time, complaining of attacks of precordial and abdominal pain, headaches, nausea, and diaphoresis.

The past and personal histories were noncontributory. The present illness had begun 21 years prior to admission, when the patient first experienced intermittent mild attacks of right-sided abdominal pain, headache, diaphoresis and nausea. They came on suddenly without any known precipitating factor, and even woke her at night. The pain spread from the abdomen superiorly to produce a severe, crushing headache. The duration of the attacks varied from a few minutes to days. Twelve years previously she had been

tolerance test was made to compare the results with the one performed preoperatively (Table 1). Preoperatively a hyperglycemic curve was noted whereas postoperatively the results showed a normal curve.

Postoperatively a histamine test was repeated (Fig. 7). This caused neither any rise in the blood pressure nor any untoward symptoms.

On December 21 the patient was discharged complaining only of residual discomfort in the right flank. When last

Postoperatively	76	152	92	105	67

seen 5 months postoperatively she had remained well and the blood pressure had continued within normal limits.

### DISCUSSION

Once the paroxysmal attacks of precordial and abdominal pain, headache and diaphoresis had been correlated with the hypertensive levels of the blood pressure, the diagnosis was apparent, and yet unproved. Recent work on dibenamine hydrochloride<sup>2</sup> has shown that this compound is adrenolytic but not sympatholytic. This action seemed desirable from both the diagnostic and the therapeutic standpoint in the case presented above.

From the diagnostic standpoint the important finding was that the blood-pressure level remained within normal limits for twenty-four hours after the administration of dibenamine and furthermore that the symptoms were relieved for seventy-two hours. The blood-pressure level when the drug was administered was of no significance in affecting the success of the test. The histamine test was of definite value in proving the diagnosis but had the disadvantage of initiating an attack. This added strain was undesirable in a debilitated patient. For the most striking results the histamine test should be done while the blood pressure is within normal limits. Recently, benzodioxane<sup>3</sup> has been reported as an adrenolytic drug of value in the diagnosis of pheochromocytoma. This drug when used while the blood pressure is elevated will lower the pressure for a period of fifteen minutes.

From the therapeutic standpoint dibenamine relieved the patient of her symptoms. Her appetite returned and she gained 10 pounds in nine days. She slept well and appeared more rested. As

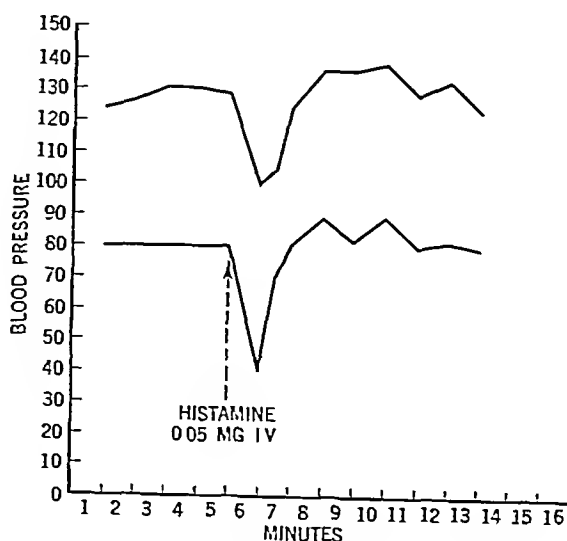

FIGURE 7 Histamine Test after Operation

a result she was prepared for operation more effectively.

### SUMMARY

The adrenolytic agent dibenamine hydrochloride was administered to a patient with a pheochromocytoma.

After the administration of dibenamine the paroxysmal elevations of blood pressure were eliminated for a period of twenty-four hours, and the patient was symptom free for seventy-two hours.

Dibenamine hydrochloride appears to be of value both in the diagnosis of a pheochromocytoma and in the therapy during preoperative preparation of the patient.

comitant administration of dye intravenously revealed a normal-appearing left kidney and adrenal area. The right kidney was displaced anteriorly by a large mass in the region normally occupied by the adrenal gland. The mass appeared to be a large adrenal tumor.

The patient was given dibenamine as outlined above. She experienced only transitory nasal congestion while receiving the infusion. Figure 2 shows the effect of dibenamine on the blood pressure when administered on two occasions 3 days apart. On both occasions the pressure dropped to normal limits within 2 hours, with an associated clearing of the symptoms. Blood-pressure readings, taken hourly, remained within normal limits for roughly 24 hours on each occasion, after which paroxysmal hypertensive episodes were again noted. At the end of 72 hours the patient had a mild headache and was losing the sense of well-being she had experienced immediately after the administration of the drug. She was given a third dose of dibenamine with similar results. During this time she regained her appetite, slept

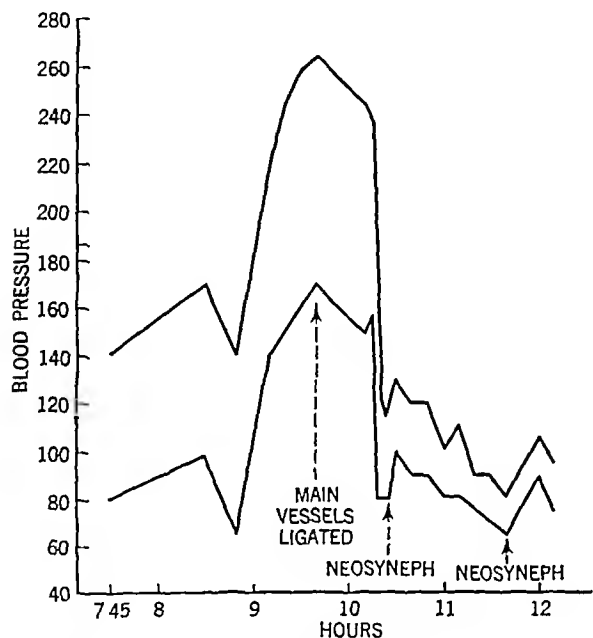

FIGURE 4 Blood-Pressure Recordings during Operation

well without interruption from an attack and regained strength as well as 10 pounds of weight.

The adrenolytic action of the dibenamine apparently had nullified the effects of the pheochromocytoma. To confirm this, histamine tests were repeated at intervals of 6, 30 and 48 hours after the administration of the drug (Fig. 3). At 6 hours there was no rise in blood pressure, and the patient felt no ill effects from the histamine. Although the tests at 30 and 48 hours were done when the blood pressure had returned to hypertensive levels, the administration of histamine did not cause a rise to levels seen in the test before the administration of the drug. Furthermore, she remained symptom free.

On the 76th hospital day, Dr. George F. Hoch, director of the Urological Service, operated on the patient. The right kidney was normal. Directly superior to the right kidney was a rounded, semi-fluctuant mass, approximately 8 cm in diameter. When the mass was dissected free, it ruptured, with the escape of tissue having the appearance and consistency of hyperplastic endometrium. The blood pressure dropped after the rupture (Fig. 4). Bleeding was controlled immediately by ligation of the pedicle of the mass. A drain was placed down to the ligated pedicle, and the wound closed. The patient was returned to her room in good condition.

On gross examination the tumor was found to be encapsulated and to contain soft, friable material, which was solid and without fibrous strands or stroma. Stained with potas-

sium bichromate, the tissue turned dark brown. Microscopically, it was composed entirely of small cells closely packed in a loose connective tissue carrying blood vessels.

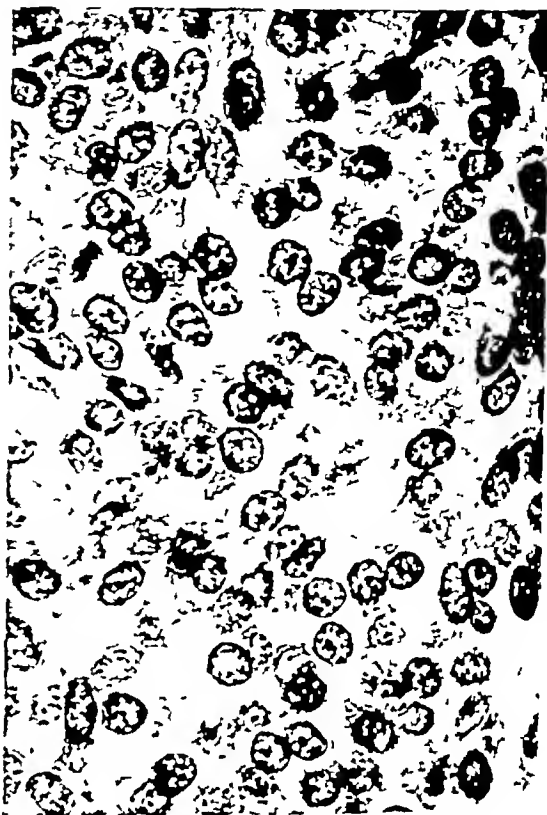

FIGURE 5 Section from Tissue Treated with Bichromate, Showing Granular Yellowish Material between the Cells (x900)

(Fig. 5) In the chromate-fixed tissue some cells contained granular, brown cytoplasm.

The postoperative course was uneventful except for a brief period of hypotension, which was controlled with neosynephrine.

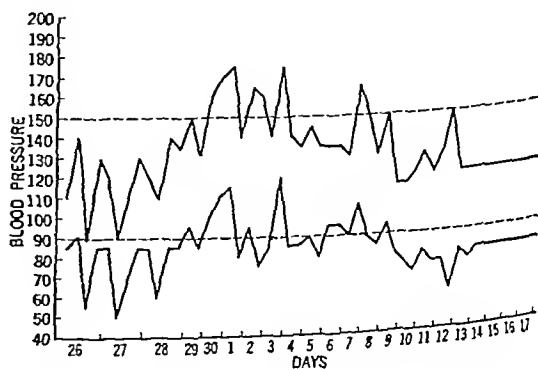

FIGURE 6 Blood-Pressure Recordings after Operation

sin. During the period of early ambulation, the blood pressure rose to levels as high as 175/120 (Fig. 6). Subsequently the level fell and stabilized at 120/80. A glucose

Museums that can afford it probably will use larger film, but unenlarged 35-mm slides of small lesions are large enough to view by magnifying glass. Cardboard mounts<sup>21</sup> are available that hold several slides, so that one mount can illustrate various signs or stages of a disease and be accompanied by explanatory text. These mounts can be clipped upon inexpensive standard lightboxes. Series of filled mounts can be stocked in reserve and, if space allows, left on display.

Enlarged transparencies in color make better displays than 35-mm film but necessitate especially constructed lightboxes. Lightboxes can be con-

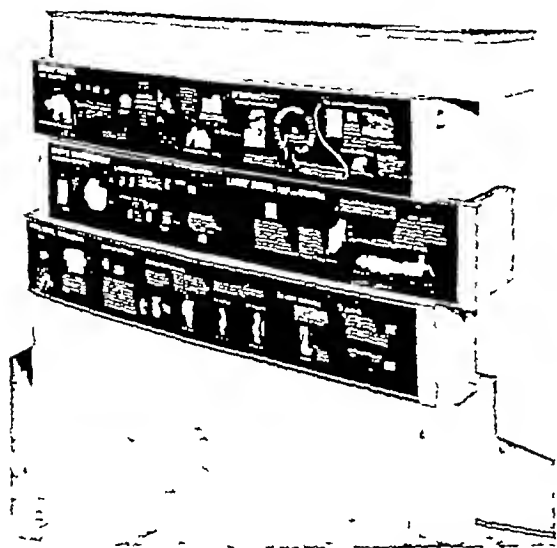

FIGURE 2 Sectional Take-Down Lightbox

structed like sectional bookcases<sup>22</sup> (Fig 2). Front panels windowed individually for each series of enlargements and screwed to such boxes are interchangeable so that extras can be held in store. If large pictures or charts are to be shown, a single front panel two or more units tall can be mounted on two or more back units.

Enlargements and viewboxes take as much space as gross specimens in jars and cost even more. But it is assumed that the photographic museum will use only a small proportion of permanent, and therefore semi-immobile, displays and that its backbone will be a store of slides for projection.

The 35-mm slide can be just as satisfactory—some,<sup>21</sup> including ourselves, prefer it in ordinary circumstances—as the 3¼-inch × 4-inch slide in projection. Small hooded screens make color projection practical in lighted rooms. Automatic projectors,\* operated by the visitor himself (Fig 3), can project sequences of 50 slides. Sequences can

be changed from week to week, and extra magazines kept loaded with those most in demand. The slide bank should be so cross-indexed that an attendant can project special sequences at request. For example, a visitor who inquires about lip lesions could be shown leukoplakia, mucous cyst, epitheliomas of varying grades of malignancy, hemangioma and chancre, preferably in conjunction with their microscopical sections, to which the film index can be keyed.

Comparative projection<sup>23</sup> has peculiar virtue: two or more projectors can demonstrate side by side the facies and the temperature chart, the gross and the microscopical appearances of a tumor, similar tumors of different grades of malignancy, contrasting graphs, a picture and a textual explanation, roentgenologic and operative appearances, and before-and-afters or, sometimes most useful of all, a normal with which deviation can be compared.

A contribution peculiar to the slide bank is the opportunity it offers of reaching beyond the walls

FIGURE 3 Photography of the Operative Field

of the museum into classroom, clinicopathological conference and staff or society meetings—that is, of bringing gross pathology to the man in practice. Clinicians are anxious to see gross disease, and color film is as logical a teaching tool in gross pathology as is the microtomic section in histopathology.

The contribution peculiar to color film is its ability to show *living* disease. Abnormal tissues, like normal, change with death, and the ordinary embalmed specimen bears no closer resemblance to living disease than does the embalmed body to the living man.

\* Available from Spindler and Sauppe, Los Angeles; and Bausch and Lomb, P. Peter, New York.

## THE PHOTOGRAPHIC MUSEUM\*

JOHN FALLON, M.D.,† AND JOHN MEYERS, M.D.‡

WORCESTER, MASSACHUSETTS

SINCE the times of Leonardo, Vesalius and John Hunter, visual teaching has been a preoccupation of medicine's greatest minds. Unfortunately it has also been, for the most part, the prerogative of that same group to indulge in it has required either artistic ability or unusual resources. Nowadays modern photography offers the privilege of visual teaching to the worker in the ranks.

Thus, 7 physicians in nonacademic group practice have assembled a pathological "museum" in a medium that is at once efficient and compatible with their funds and space. 35-mm color film. A few enlargements in viewboxes, viewing and projection paraphernalia and 7000 slides are contained in a space no larger than a good-sized closet (Fig. 1).

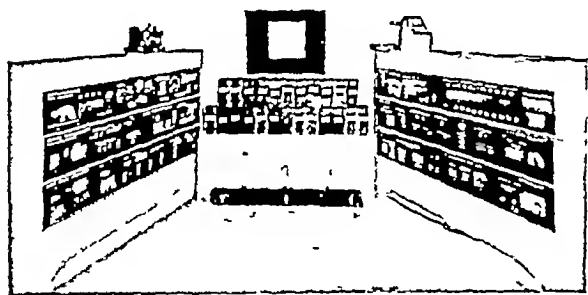

FIGURE 1 A Pocket Museum

The largest — and least important — constituents are the light-boxes for enlargements. All other items — the projector, automatic projector, rolled screen, hooded daylight screen, 7000 filed 35-mm color slides and (not illustrated) collapsible lightboxes for sheets of unenlarged slides — would fit into a large trunk.

The collection was built upon principles laid down some years ago and amplified here because of the growing interest in photographic museums<sup>4-11</sup> and because of the belief that some of the findings in a test case might be projected into more important endeavors.

The museum of gross specimens has two advantages over the photographic museum. Specimens offer third dimension and the possibility of microscopical restudy. However, color transparencies give fair third-dimensional illusion — better than that of black-and-white prints. Then, too, specimens after being photographed can be stored inexpensively in formaldehyde tanks for later study.

\*From the Surgical and the Medical Sections of the Fallon Clinic and the St. Vincent Hospital.

†Surgeon Fallon Clinic surgeon St. Vincent Hospital.

‡Physician Fallon Clinic assistant physician St. Vincent Hospital.

The photographic museum has advantages of its own. Thus, in the Buffalo Museum of Science

First — It has been found that transparencies and photographs hold the interest when original objects do not. Second — In some cases transparencies of a complete object make an original fragment intelligible. Third — In many instances they divert the attention back to the original.<sup>12</sup>

Photographic color is truer than the color of preserved gross tissue. Color usually disappears from the preserved specimen in a year or so.<sup>13</sup> Color slides last several years; how many we do not yet know. Specimens shrink and distort.<sup>14</sup> In an audience, specimens must pass slowly from hand to hand. Photographs are projected, or transilluminated, for all at the same time. If 35-mm film is used, 600 slides can be filed in the space required for 1 medium-sized specimen jar. Slide making is fast and efficient, while the preparation in color of actual tissue is time taking and puttery. Jars or watch glasses require frequent servicing, cleaning, refilling and resealing. The cost of preparing a gross specimen approximates three dollars, and that for taking and filing a slide nineteen cents. These are material expenses and include neither the cost of space and the salary for museum diener on the one hand nor the photographer's salary on the other. Without a biophotographer the photographic museum must remain, like ours, amateur.

The amateur — that is, the doctor — can with some study and effort take many of his own pictures.<sup>2, 3, 15-17</sup> He will meet a helpful welcome from the professionals of the Biological Photographic Association,<sup>18</sup> and he will find that composing pictures, like sketching, sharpens his eyes<sup>19</sup> and that his pictures will receive disproportionate praise from those whose photographic knowledge is a little scantier than his own. However, our kindest compliment, awarded some views of operative fields and recorded here with no pretense of modesty, was "Who does your surgery for you?" The fact that we were elated when the best of many amateur pictures thus were mistaken for routine professional results is a measure of the difference between amateur and professional. Professional photography is one of the few remaining bargains in medical care. Martinsen<sup>20</sup> reported in 1940 that the average of 110 full-time and part-time biologic photographic departments employed 1 1/4 persons, occupied 730 square feet of floor space, cost \$3146 yearly (of which 40 per cent went for materials) and used equipment valued at \$3109.

cases of sarcoidosis proved by biopsy with 18 different tuberculin, but noted no significant difference in reaction from 5 normal controls

### *Leprosy*

The occurrence of leprosy in a tuberculoid form that may be histologically indistinguishable from sarcoidosis<sup>248-249</sup> has suggested to a number of authors that the lepra bacillus or a closely related organism is an etiologic agent<sup>250-251</sup>. Further support has been lent to this view by the fact that in such tuberculoid forms, bacilli are so few as to be difficult or impossible to demonstrate by ordinary methods,<sup>248-252-253</sup> and that animal inoculations with lepra bacilli are invariably unsuccessful. Rabello<sup>250</sup> also notes that a torpid and discrete adenopathy analogous to that of sarcoidosis both clinically and histologically is frequently seen in such cases, and that characteristic pulmonary and osseous lesions may also occur, as well as tuberculin anergy. Cystic bone changes in the phalanges closely resembling those seen in sarcoidosis have also been described by others.<sup>5-134</sup>

There seems little doubt that leprosy is capable of mimicking at least part of the sarcoid picture, and it seems quite likely that some cases reported are, in fact, leprosy. Pardo-Castello<sup>248</sup> is of the opinion that sarcoid disease due to leprosy is indistinguishable from any other form of the disease, and Boeck himself is reported to have diagnosed a case of tuberculoid leprosy as a cutaneous sarcoid<sup>254</sup>. Whether leprosy can reproduce the entire clinical and pathological picture of sarcoidosis is another matter, however, and is considered by a number of authors as highly unlikely.<sup>255-256</sup> Furthermore, the tuberculoid forms of leprosy are almost invariably associated with the neural type of the disease<sup>248-257</sup>, in such cases the peripheral nerves show direct invasion,<sup>172</sup> something that must be exceedingly rare in sarcoidosis if it occurs at all.

Some efforts have been made to analyze this problem on the basis of immunologic reactions. Weeks and Smith<sup>255</sup> performed skin tests on 10 proved cases of sarcoidosis. They found 6 to be negative to both lepromin and tuberculin, whereas 2 were positive to both. Of 5 other cases similarly tested by Harrell and Horne,<sup>259</sup> 2 were negative to lepromin, and 3 gave a faintly positive reaction considered nonspecific, of the latter, 2 were tuberculin positive as well. Thus, in practically all 15 cases, the results with lepromin either were negative or could be explained on the basis of a cross reaction with tuberculin, which has been demonstrated to exist by a number of investigators.<sup>260-262</sup> This is in marked contrast with the fact that unlike the frequently weak or negative tuberculin reactions seen in sarcoid patients, the lepromin reactions in the tuberculoid (or sarcoid) forms of leprosy are strongly positive in 90 to 100 per cent of cases.<sup>248-252-263</sup> Fifteen

cases are admittedly a small sample on which to base conclusions, but in view of these findings it seems highly unlikely that, in this country at least, the tuberculoid form of leprosy masquerades as sarcoidosis in any appreciable number of patients. In such cases, the lepromin test might be expected to prove a useful aid in diagnosis.<sup>259</sup>

### *Other Infectious Diseases*

A number of granulomatous diseases known to be capable of wide dissemination have also come under suspicion, and several have been shown to exist in a sarcoid form. In all such cases organisms may be very difficult to find, and, as in tuberculosis and leprosy, both the prompt destruction of the organisms and the morphologic character of the lesions may be explainable by the same altered immunologic status of the host. Regardless of etiologic relation, however, the various disseminated granulomas frequently pose a difficult problem in differential diagnosis, and it is certain that they have been confused with sarcoidosis on more than one occasion.

**Brucellosis** In view of its ability to involve practically every organ in the body, its frequently low-grade chronic course, its association with non-caseating granulomas and its world-wide distribution, brucellosis has been considered a possible cause. It is quite possible that typical sarcoid lesions may be produced, though the usual lesions tend to be much less distinct with proliferation of cells of the reticuloendothelial system, and occasionally suppuration.<sup>264</sup> Pulmonary involvement may resemble that of sarcoidosis,<sup>265</sup> iridocyclitis may occur, and the bones may be involved as well, the characteristic bone changes of sarcoidosis have not been described, however. In the cases in which specific skin or agglutination tests have been performed they have all been negative, and Harrell<sup>42</sup> found that guinea pigs injected with tissue from sarcoid patients remained negative to brucellergin. These arguments do not, of course, constitute proof but simply indicate that brucellosis in its usual form is not sarcoidosis. It is well known that failure to culture the organism or to obtain positive skin or agglutination tests does not necessarily rule out the disease,<sup>264</sup> whereas, on the other hand, occasional positive findings might indicate little more than their coexistence.

**Syphilis** A number of cases reported as cutaneous sarcoidosis may have been due to syphilis.<sup>266-267</sup> As noted above, however, the serologic reactions are negative in the large majority of sarcoid patients so that it seems unlikely that syphilis can be the responsible agent in any appreciable number of cases.

**Mycoses** Some attempts have been made to implicate various yeasts and fungi as etiologic agents, usually on the basis of a similar pulmonary picture. Organisms such as aspergillus and

developed in an attempt to explain this peculiar immunologic situation

**Spontaneous desensitization** It has been known for a long time that skin sensitivity to tuberculin may be gradually lost—even to a degree whereby the subject may fail to react to large doses.<sup>232</sup> Tuberculin sensitivity induced by BCG vaccination may also be lost.<sup>233, 234</sup> Desensitization occurs spontaneously in animals<sup>235</sup> and has been produced experimentally by injections of tuberculin without impairment of immunity to reinfection.<sup>236, 237</sup> It has been postulated, therefore, that a similar effect may be produced by repeated hematogenous dissemination of tubercle bacilli as might be the case in sarcoidosis.<sup>120</sup>

If this theory is so, a reinfection with tubercle bacilli might be expected to cause a return of hypersensitivity as has been demonstrated experimentally.<sup>235, 238, 239</sup> As a matter of fact, it has occasionally been noted that a previously negative tuberculin test has become positive during or after a sanatorium stay or in the course of development of caseating tuberculosis in a sarcoid patient.<sup>7, 230</sup> In a number of cases the altered reactivity has preceded the clinical manifestations of active tuberculosis by several months.<sup>38</sup> On the other hand, vaccination of sarcoid patients with BCG, even in two or three times the usual dose, may fail to produce a positive tuberculin test,<sup>210, 211</sup> or may produce only a delayed or slightly positive reaction.<sup>226, 240</sup> Experimental reinfection of desensitized animals with very small numbers of attenuated or nonpathogenic acid-fast bacilli, however, has also resulted in marked delay or suppression of the development of hypersensitivity in comparison with controls,<sup>238, 239</sup> and repeated injection of attenuated bacilli into guinea pigs has caused some of them to lose their hypersensitivity while retaining their resistance.<sup>241</sup> These findings constitute no convincing proof but are at least sufficiently challenging to warrant further investigation.

**Anticutins** Substances capable of neutralizing the skin sensitivity to tuberculin (anticutins) or enhancing it (procutins) have been demonstrated in the blood serum of patients with sarcoid lesions associated with lack of tuberculin hypersensitivity.<sup>222, 228, 242</sup> Similar neutralizing substances have been demonstrated in the rat,<sup>228</sup> an animal that fails to develop tuberculin hypersensitivity after infection. The significance of the latter, however, has been questioned on the grounds that the rat is constitutionally resistant to hypersensitivity reactions in general.<sup>243</sup>

Pinner, Weiss and Cohen<sup>244</sup> have recently studied these substances in a small number of

normal, tuberculous and sarcoid persons. Anticutins were demonstrated in only 4 (36 per cent) of 11 patients with sarcoidosis; they were also demonstrable in 18 per cent of various groups of tuberculous patients—the highest percentage being in a group of 23 such patients with a low degree of hypersensitivity—and in 3 to 9 per cent of normal subjects. Procutins were found in another 36 per cent of the sarcoid patients. The authors were forced to conclude that anticutins played no significant immunologic role in sarcoidosis. Other authors have also failed to demonstrate them.<sup>44</sup>

**Local fixation of antibodies** This theory, supported by Leitner,<sup>55, 177</sup> suggests that in sarcoid patients the antigenic substances of the tubercle bacillus fix antibodies locally at their sites of origin (the reticuloendothelial system), and thus skin sensitization is prevented. Such a concept assumes the presence in tuberculosis of antibodies with secondary tissue-cell sensitization, but this has not yet been proved.

**Epidemiologic arguments** The majority of sarcoid patients give no history of unusual exposure to tuberculosis.<sup>10, 24</sup> although there is disagreement on this point.<sup>86</sup> In the various families and sibling pairs in which the disease has occurred, however, a significant incidence of tuberculosis has been recorded.<sup>49, 53, 56</sup> Such cases are interesting and possibly significant, but so far represent too small a proportion of the total cases reported to permit accurate evaluation. It is impossible at present to divorce the factors of infection, environment and constitution, or to establish for certain whether or not the incidence of tuberculosis in these groups differs in any way from that in other comparable groups.

In summary, the case for tuberculosis rests largely on negative, circumstantial or controversial evidence, a point freely admitted by at least one of its supporters.<sup>191</sup> The tubercle bacillus has not, however, been excluded as a possible etiologic factor. The validity of the few positive bacteriologic findings remains a crucial point, and here the issue has reached a stalemate. If, as is often the case, the identification of tubercle bacilli is accepted as *a priori* evidence that the case is one of tuberculosis and, therefore, not sarcoidosis, it is difficult to see how the point can be proved from a bacteriologic standpoint at least.

It has been suggested that other forms of tubercle bacilli, or related bacilli, are the responsible agents, but, in general, the arguments on both sides are the same as those already presented. Bacilli of the bovine<sup>7, 245</sup> and avian<sup>246</sup> strains have been reported in sarcoid lesions but, as in the human form, the majority of inoculations into susceptible animals has been negative. Immunologic studies have also provided little clue. Brooke and Day<sup>247</sup> tested 7

cases of sarcoidosis proved by biopsy with 18 different tuberculins, but noted no significant difference in reaction from 5 normal controls

### Leprosy

The occurrence of leprosy in a tuberculoid form that may be histologically indistinguishable from sarcoidosis<sup>248-249</sup> has suggested to a number of authors that the lepra bacillus or a closely related organism is an etiologic agent<sup>250-251</sup>. Further support has been lent to this view by the fact that in such tuberculoid forms, bacilli are so few as to be difficult or impossible to demonstrate by ordinary methods,<sup>248-252-253</sup> and that animal inoculations with lepra bacilli are invariably unsuccessful. Rabello<sup>250</sup> also notes that a torpid and discrete adenopathy analogous to that of sarcoidosis both clinically and histologically is frequently seen in such cases, and that characteristic pulmonary and osseous lesions may also occur, as well as tuberculin anergy. Cystic bone changes in the phalanges closely resembling those seen in sarcoidosis have also been described by others.<sup>8-184</sup>

There seems little doubt that leprosy is capable of mimicking at least part of the sarcoid picture, and it seems quite likely that some cases reported are in fact, leprosy. Pardo-Castello<sup>248</sup> is of the opinion that sarcoid disease due to leprosy is indistinguishable from any other form of the disease, and Boeck himself is reported to have diagnosed a case of tuberculoid leprosy as a cutaneous sarcoid<sup>254</sup>. Whether leprosy can reproduce the entire clinical and pathological picture of sarcoidosis is another matter, however, and is considered by a number of authors as highly unlikely.<sup>255-256</sup> Furthermore, the tuberculoid forms of leprosy are almost invariably associated with the neural type of the disease<sup>248-257</sup>, in such cases the peripheral nerves show direct invasion,<sup>172</sup> something that must be exceedingly rare in sarcoidosis if it occurs at all.

Some efforts have been made to analyze this problem on the basis of immunologic reactions. Weeks and Smith<sup>258</sup> performed skin tests on 10 proved cases of sarcoidosis. They found 6 to be negative to both lepromin and tuberculin, whereas 2 were positive to both. Of 5 other cases similarly tested by Harrell and Horne,<sup>259</sup> 2 were negative to lepromin, and 3 gave a faintly positive reaction considered nonspecific, of the latter, 2 were tuberculin positive as well. Thus, in practically all 15 cases, the results with lepromin either were negative or could be explained on the basis of a cross reaction with tuberculin, which has been demonstrated to exist by a number of investigators.<sup>260-262</sup> This is in marked contrast with the fact that, unlike the frequently weak or negative tuberculin reactions seen in sarcoid patients, the lepromin reactions in the tuberculoid (or sarcoid) forms of leprosy are strongly positive in 90 to 100 per cent of cases.<sup>248-252-253</sup> Fifteen

cases are admittedly a small sample on which to base conclusions, but in view of these findings it seems highly unlikely that, in this country at least, the tuberculoid form of leprosy masquerades as sarcoidosis in any appreciable number of patients. In such cases, the lepromin test might be expected to prove a useful aid in diagnosis.<sup>259</sup>

### Other Infectious Diseases

A number of granulomatous diseases known to be capable of wide dissemination have also come under suspicion, and several have been shown to exist in a sarcoid form. In all such cases organisms may be very difficult to find, and, as in tuberculosis and leprosy, both the prompt destruction of the organisms and the morphologic character of the lesions may be explainable by the same altered immunologic status of the host. Regardless of etiologic relation, however, the various disseminated granulomas frequently pose a difficult problem in differential diagnosis, and it is certain that they have been confused with sarcoidosis on more than one occasion.

**Brucellosis** In view of its ability to involve practically every organ in the body, its frequently low-grade chronic course, its association with non-caseating granulomas and its world-wide distribution, brucellosis has been considered a possible cause. It is quite possible that typical sarcoid lesions may be produced, though the usual lesions tend to be much less distinct with proliferation of cells of the reticuloendothelial system, and occasionally suppuration.<sup>264</sup> Pulmonary involvement may resemble that of sarcoidosis,<sup>265</sup> iridocyclitis may occur, and the bones may be involved as well, the characteristic bone changes of sarcoidosis have not been described, however. In the cases in which specific skin or agglutination tests have been performed they have all been negative, and Harrell<sup>42</sup> found that guinea pigs injected with tissue from sarcoid patients remained negative to brucellergin. These arguments do not, of course, constitute proof but simply indicate that brucellosis in its usual form is not sarcoidosis. It is well known that failure to culture the organism or to obtain positive skin or agglutination tests does not necessarily rule out the disease,<sup>264</sup> whereas, on the other hand, occasional positive findings might indicate little more than their coexistence.

**Syphilis** A number of cases reported as cutaneous sarcoidosis may have been due to syphilis.<sup>266-267</sup> As noted above, however, the serologic reactions are negative in the large majority of sarcoid patients so that it seems unlikely that syphilis can be the responsible agent in any appreciable number of cases.

**Mycoses** Some attempts have been made to implicate various yeasts and fungi as etiologic agents, usually on the basis of a similar pulmonary picture. Organisms such as aspergillus and

monilia have been found in the sputum of patients on occasion,<sup>30</sup> but these organisms are often saprophytic and do not necessarily possess etiologic significance. Cutaneous tests with blastomyces filtrates, monilia vaccine or coccidioidin, when done, have given negative or at best faintly positive results.<sup>42-47</sup>

Histoplasmosis occurs as a disseminated disease capable of involving most of the organs of the body and is now known to be world-wide in distribution.<sup>265</sup> It may also produce granulomatous lesions in which organisms are rare or absent.<sup>269</sup> The much higher incidence of histoplasmosis in infants and young children, the high male-sex incidence in the adult, the common presence of mouth and gastrointestinal lesions, the rarity of eye lesions and the high susceptibility of most laboratory animals<sup>265</sup> are findings at considerable variance with those of sarcoidosis, as in tuberculosis and brucellosis, however such data prove only that the usual form of histoplasmosis is not sarcoidosis.

Tornell<sup>270</sup> has pointed out the resemblance between the radiologic picture of the lung in sarcoidosis and that of "thresher's lung," a form of moniliasis, or possibly histoplasmosis, due to inhalation of burnt grain. This disease is acute, but he suggests that chronic exposure of susceptible persons to moldy dusts, as in cellars and attics, could produce a similar picture. Since the pulmonary picture of sarcoidosis is nonspecific, however, such arguments are unconvincing. The same thing may be said for such equally nonspecific manifestations as erythema nodosum, the occurrence of which in both sarcoidosis and coccidioidomycosis led Kerley<sup>168</sup> to suggest an etiologic relation.

**Leishmaniasis** Sarcoid forms of leishmaniasis have been described,<sup>271</sup> and certain clinical features such as hepatosplenomegaly and hyperproteinemia are suggestive. This seems an unlikely cause in most cases, however. Careful searches have been made for the organism in some cases without success,<sup>24</sup> but in some known cases of leishmaniasis, organisms may be very rare and difficult to find.<sup>272</sup>

**Virus diseases** The inability to identify organisms in the lesions of most cases has suggested a virus etiology to some authors. Attempts to implicate the virus of lymphogranuloma inguinale by means of the Frei test, at least, have usually been negative. The Kveim antigen, at first regarded as strong evidence for a virus etiology, has been shown to be nonspecific and highly thermostable.<sup>206-208</sup> If a virus is indeed the cause of sarcoidosis, it has yet to be demonstrated.

#### *Inorganic Agents*

The resemblance of the pulmonary forms of sarcoidosis to some of the pneumoconioses has suggested that they are related. The clinical course of silicosis, as well as the absence of silica in abnor-

mal amounts in the sarcoid lesions, seems to rule this out rather definitely. Sarcoidosis has been described in association with asbestosis on at least one occasion,<sup>273</sup> but the two types of lesions appeared distinct.

**Beryllium** The chronic form of a pulmonary disease occurring in workers exposed to compounds of beryllium bears sufficient resemblance to sarcoidosis to have suggested their identity to some authors.<sup>274</sup> The pulmonary picture may, in its later stages at least, closely simulate the roentgenologic findings of sarcoidosis, and some patients have also exhibited hilar and peripheral adenopathy, enlarged liver and spleen, and skin lesions. Moderate elevations in serum globulin and calcium have been observed, and in 1 case an elevated blood calcium was associated with renal stone.<sup>275</sup> Tuberculin tests have also been negative in a number of cases.<sup>276</sup> On histologic examination, granulomatous lesions composed of epithelioid and giant cells have been found in the lungs, lymph nodes, liver and skin, and deep-staining, concentrically laminated inclusion bodies of the type described by Schaumann in sarcoidosis have also been seen.<sup>72-73</sup>

Claims for identity of the two conditions, as with other suggested etiologic agents, stress individual similarities and ignore the clinical picture as a whole. Unlike the usual case of sarcoidosis, which tends to be asymptomatic or practically so, the so-called delayed chemical pneumonitis or pulmonary granulomatosis is characterized by severe dyspnea, anorexia, weight loss, gastrointestinal disturbances and often cough and cyanosis. The disease is frequently progressive to the point of incapacitation, and cor pulmonale with right-sided heart failure frequently supervenes. In 45 cases collected by Hardy,<sup>276</sup> at least 7 patients died, and only a few recoveries after prolonged illness have so far been reported. Bone lesions have not been seen. Even the roentgenographic picture of the lungs resembles sarcoidosis only in its later stages and, as such, is hardly pathognomonic, whereas the earlier "sand-storm" appearance has been considered by some to be entirely unique.<sup>77, 77</sup>

Histologic examination of the lungs of these patients reveals granulomatous lesions, but the general picture bears only a superficial resemblance to that of sarcoidosis. Similar granulomas have been seen in lymph nodes and other organs. Histologic lesions closely simulating those of sarcoidosis have been noted in the skin of 2 patients with the chronic pulmonary disease, and in 3 others who cut themselves on broken fluorescent lamps.<sup>77</sup> In most of these lesions, however, foci of necrosis of a type never seen in sarcoidosis have been present. The relatively limited exposure to beryllium compounds makes this an unlikely cause for any great number of sarcoid cases, particularly since sarcoidosis obviously antedates the wide-

spread industrial use of beryllium. Nevertheless it is possible that a few cases, particularly some with marked pulmonary fibrosis, dyspnea and cor pulmonale, have been so caused. The long delay in onset following exposure — up to five years in some cases — and the occurrence of the disease in persons who have lived close to, but never worked in, factories using beryllium<sup>276 278</sup> may account in part for failure to obtain a history of exposure in such patients.

#### *Nonspecific Agents*

Localized sarcoid lesions have been observed following a wide variety of nonspecific stimuli, including the introduction into the tissues of such substances as paraffin and various medicated oils<sup>279-281</sup> morphine, iron and arsenic preparations,<sup>282 283</sup> and glass and stone fragments<sup>75 76</sup>. Similar lesions have been noted at the sites of previous operations<sup>29</sup> or after trauma without known introduction of foreign substances into the tissue<sup>76</sup>. In many of these cases the histologic descriptions are inadequate, and some of them may simply represent foreign-body reaction, a few, however, have been of characteristic sarcoid structure. The granulomas are of the subcutaneous type, infiltrating connective tissue and muscle, and have in the past been grouped with the subcutaneous sarcoids of the so-called Darier-Roussy type. Giant cells may be numerous, and often contain asteroid or refractile inclusions. An interesting feature in most of these cases has been the long latent period between the traumatic episode and the onset of the lesion — varying from months to many years, a few have recurred after incomplete excision. It is possible that some of the isolated sarcoid lesions in the intestinal tract and other areas, as well as the local skin lesions produced by beryllium compounds, belong in this category.

Since the other features of sarcoidosis have not been associated, there is no justification for such a diagnosis in these cases. The wide variety of agents that seem capable of inducing such reactions — and the agent producing disseminated sarcoidosis appears to be only one — suggests some common underlying mechanism in their formation. Phospholipids, either introduced into the body or freed nonspecifically at the site of reaction, may represent such a common factor,<sup>22 176 284</sup> though in at least one study such substances have failed to cause characteristic reactions in patients with sarcoidosis<sup>287</sup>. It is possible, too, that foreign material capable of inducing a local histiocytic or reticuloendothelial response in some cases provides a site for localization of the etiologic agent of sarcoidosis during periods of dissemination such a phenomenon is suggested by the occurrence of positive Heim reactions only in patients with active disease. Whatever the responsible agent, however, an altered state of reactivity, either constitutional

or acquired — in effect, the *terrain sarcoidique* of the early French authors<sup>288</sup> — may well be a contributory factor in the genesis of the lesions.<sup>4 83 286</sup>

*Allergy.* Certain features of sarcoidosis, such as the so-called tuberculin anergy and the occasional occurrence of such allergic manifestations as eosinophilia and erythema nodosum, suggest that hypersensitivity plays a role in the disease. There is recent experimental evidence to indicate that granulomas of histiocytic and even epithelioid character are associated with anaphylactic response<sup>287</sup>. Teilum<sup>82</sup> has also postulated an allergic basis for the hyalinization of sarcoid lesions. According to this concept, such changes are related to the hyperglobulinemia, and have as their starting point a globulin precipitate, especially in the reticuloendothelial system, these precipitates are gradually transformed, either within or outside the granuloma, into a homogeneous substance resembling amyloid (paramyloidosis or hyalinosi). Similar changes are described in other disorders associated with hyperglobulinemia such as Letterer-Siwe's disease, lupus erythematosus and lymphogranuloma inguinale and are interpreted as the result of persistent and repeated stimulation of immune mechanisms.

\* \* \*

Progress in the understanding of sarcoidosis in recent years has largely been limited to clarification of the clinical picture and recognition of some of the pitfalls in diagnosis. It has been amply demonstrated that no single feature of the disease is sufficient for diagnosis, and many errors have been made through the too-frequent substitution of the part for the whole. The pulmonary roentgenographic picture may be simulated by erythema nodosum, the mycoses, beryllium granulomatosis and a host of other conditions, the bone lesions by leprosy, the histologic picture by many agents both specific and nonspecific.

Most of the features of the disease are consistent with those of a chronic infection having a special predilection for the tissues of the reticuloendothelial system. Even the electrophoretic patterns obtained in examination of the blood proteins have been similar to those seen in other chronic infections, and a differential diagnosis between sarcoidosis and other widely disseminated infections is often exceedingly difficult. It is these close resemblances in fact, that have given rise to most of the etiologic theories. Clinical diagnosis is further complicated by the fact that the disease progresses and regresses irregularly, with various localizations becoming evident or disappearing without definite temporal relation, or even stabilizing for long periods. It may therefore be necessary to follow some suspects for a considerable time before characteristic localizations make their appearance and definite diagnosis is possible. Obviously the

greater the number of such localizations, the more certain the diagnosis will be

Considerable confusion has also resulted in the past from the assumption that the morphologic appearance of the lesion is pathognomonic. When typical, the sarcoid lesion is highly characteristic, but many cases show sufficient departure from the generally accepted norm to make histologic differentiation from miliary tuberculosis, brucellosis or other granulomatous disease practically impossible. So little is actually known of the genesis of these lesions, particularly their early phases, that the extent of permissible variation is still largely a matter of conjecture, and pathologists disagree considerably among themselves regarding the morphologic criteria for diagnosis.

Even granting the presence of a typical sarcoid lesion, this alone cannot be construed to constitute diagnostic proof. A wide variety of agents, of which the unknown cause of sarcoidosis appears to be only one, seem capable of inducing the characteristic granuloma, and it has become increasingly clear that a careful distinction must be made between the "sarcoid lesion" and the disease "sarcoidosis." The evidence provided by biopsy is essential, but constitutes only one link in the chain of evidence required in making a reliable diagnosis.

The Kveim test, which has been found to be positive in a fair percentage of patients with active sarcoidosis, seems to be a significant recent development. The test in its present form is not especially practical as a means of diagnosis, but it may well shed some much needed light on the question of pathogenesis. In particular, the nonspecific character of the Kveim antigen raises again the question of altered tissue reactivity on the part of the host, a condition that may also account for the well known and puzzling tuberculin insensitivity of many patients. Preoccupation with tuberculin, unfortunately, has resulted in too little investigation of reactivity to other substances, and it is possible that sarcoid patients tested in appropriate endemic areas might show a refractiveness to coccidioidin, histoplasmin or lepromin of the same order as that to tuberculin. The sporadic tests so far performed with such substances have usually been negative but as a rule have been done in nonendemic areas. Any such group would, of course, require careful diagnostic screening since all these conditions can simulate sarcoidosis in one way or another.

The etiologic issue is still far from solution and has made little or no progress in more than twenty years. The tubercle bacillus and some unknown agent, perhaps a virus, remain the most favored possibilities but no real proof has yet been offered. An organism of the brucella group may also be involved. Whether further careful bacteriologic or viral studies, or study of inoculated animals for longer periods, will shed more light on this issue

remains to be seen, but this approach does not seem to be particularly hopeful at present.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY MD, Editor

BENJAMIN CASTLEMAN, MD, Associate Editor

EDITH E PARRIS, Assistant Editor

### CASE 34461

#### PRESENTATION OF CASE

**First admission.** A five-year-old girl was admitted to the hospital with a small nonpainful lump in the right axilla which had been present for a year and had increased in size over this period and spread up under the clavicle. Immediately before admission to this hospital the child had been taken to a clinic because of tonsillitis. Chest x-ray films were reported at this time to show an "intrathoracic tumor." An exploratory operation showed "a gravish, rosy, polycystic mass." The outer portion was attached to the fibers of the pectoralis major, and the inner portion extended deep to the pectoralis and disappeared under the clavicle. Following this the patient was admitted to this hospital.

Physical examination showed a moderately well nourished underdeveloped child. The right pupil was smaller than the left and eccentrically placed. There were numerous large pigmented areas over the entire body, with the exception of the lower extremities. The superficial veins of the right upper chest were prominent and the right arm appeared cyanotic. Masses were present immediately beneath the skin in the right axilla and in the right

supraclavicular fossa. The right upper chest was dull anteriorly and posteriorly, and the breath sounds were decreased. At the extreme apex there was an area of bronchial breathing. The pulse at the left wrist was greater than that on the right. The only positive neurologic finding was weakness of the right hand. Urine and blood examinations were negative. A chest x-ray examination was reported as follows: "Findings are those of a large mass in the upper mediastinum rising posteriorly, probably lobulated, a smaller lobe being on the left side, with soft-tissue masses in the right supraclavicular and right axillary region." An operation was performed through a paravertebral approach and portions of the second, third and fourth ribs on the right were resected. The tumor was found to be a neurofibroma of the invasive type, but a large portion was removed and the brachial plexus was freed. The patient did well postoperatively and was discharged on the twenty-fourth hospital day.

**Final admission** (twelve years later). In spite of the progressive character of the disease, resulting in increasing skeletal deformity, exertional dyspnea and also apparent hypogonadism, the patient completed school and was able to accept summer employment. In this interval she received some radiation treatment. One year before admission while being followed at another clinic the tumor in the right side of the neck began painlessly to increase in size. Four weeks before admission her voice weakened and became hoarse. Two weeks before admission she suddenly awakened with extreme shortness of breath. This was not associated with pain or cough or sputum and since then she had slept in a semi-squatting position with her legs tucked under her. Following this she noted swelling around the eyes, face and neck, most marked in the morning, and most severe on the left side. Difficulty in swallowing large mouthfuls was noted and severe supraorbital headaches, worse at night than

in the morning. There was no history of chills, fever or weight loss.

On physical examination the patient was poorly developed, orthopneic and markedly kyphoscoliotic. There were small plaques of pigmentation over the arms and trunk, with a marked area extending from the anterior axillary line at the level of the nipple extending along the medial surface of the right arm and involving the axilla. A firm, smooth fixed mass, 15 cm in its longest diameter, was present in the right supraclavicular area. There were small, shotty nodules in the right axilla and beneath the skin along the posterior axillary line. The superficial veins of the neck on both sides were distended, and the veins of the right hand failed to empty on full elevation. The blood pressure was 110 systolic, 80 diastolic, in both arms. The left border of the heart reached the left anterior axillary line. The temperature, pulse and respirations were normal. There was extreme weakness and areflexia in the right upper extremity. There was marked sexual underdevelopment. An electrocardiogram was normal. An x-ray examination of the chest was reported as follows: "There is marked, severe kyphoscoliosis of the dorsal lumbar spine so that the heart is on the right side of the thorax. Size and shape of the heart cannot be determined because of the severe deformity. There has been partial resection of the right upper ribs. A soft-tissue tumor is present over the dorsum of the right side of the chest." Urinalysis was negative. Blood examination showed a hemoglobin of 12.5 gm, and a white-cell count of 11,000, with a normal differential.

While in the hospital she developed rather severe precordial pain, which was pounding in character and located over the apex. There was very little that could be done for this girl except to supply sedation. On the eighth hospital day while she was sleeping at night it was noted by the nurse that respirations had stopped but the pulse was still present. Resuscitation measures were of no avail.

#### DIFFERENTIAL DIAGNOSIS

DR. EARLE M. CHAPMAN: May we see the x-ray films?

DR. JOSEPH HANELIN: There is an extremely severe spinal deformity, rather marked kyphoscoliosis or perhaps mostly scoliosis. The heart is just visible within the right thorax. There have been resections of the right upper ribs, and some rib regeneration has taken place. There is no obvious explanation for the scoliosis in the way of any structural or bony abnormality. There is evidence of a soft-tissue tumor in the right side of the thorax. There is a mass in the region of the right axilla. In the lateral view of the chest, which includes a large part of the patient, the abdomen appears to be somewhat protuberant. There is soft-tissue density present, with a lobulated appearance, which is observed to extend through the dorsal aspect of the

thoracic wall. I cannot be certain that this lesion is within the thoracic cavity although this is a general situation and cannot be interpreted particularly without stereoscopic films because of the marked deformity.

DR. CHAPMAN: May I ask if you see any area in the bony structure that suggests metastatic or destructive lesions?

DR. HANELIN: No, I do not.

DR. CHAPMAN: Do you see any lesions in the vertebral column?

DR. HANELIN: No, I see no lesions at all in the vertebrae.

DR. CHAPMAN: Is this a right dorsal kyphoscoliosis?

DR. HANELIN: It is to the left.

DR. JOSEPH AUB: May I add some information that Dr. Chapman ought to have? The patient had extreme cyanosis of the face and really had an enormous amount of dyspnea, which I do not think the record makes clear.

DR. CHAPMAN: From the evidence at hand it seems to me that this girl suffered from two diseases, either one of which alone would have brought about her death, and certainly both together have done so. The first is that she had multiple neurofibromatosis of the invasive type, diagnosed histologically here in this hospital twelve years before death. Then on top of these tumors that no doubt were multiple, she had an increasing deformity of the chest, which we are told was a left kyphoscoliosis compressing the lungs and the soft tissues within the chest to the point where the vital capacity was greatly diminished. Life was a battle. She was struggling to live in the face of great diminution of the pulmonary reserve, and she must have had what I once called pulmonocardiac failure.<sup>1</sup> The interference with breathing, the cyanosis and the description here indicate that there was also occlusion of venous return in the superior mediastinal region. One would think that the tumor produced a superior mediastinal syndrome more marked on the right than on the left according to the description. Beyond that I think any remarks are purely speculative as to what might be found at autopsy. I think, however, the description of the hypogonadism and the statement of the sexual underdevelopment warrant a few remarks. I would like to have information, for instance, whether or not the 17-ketosteroids were determined. I judge they were not done.

DR. JACOB LERMAN: No.

DR. CHAPMAN: There are perhaps androgen-producing tumors of the adrenal glands that could produce some of the signs present. One wonders if neurofibroma was present in the adrenal area or if one or both of the adrenal glands were involved in this type of tumor. One wonders if she had some other type of hormonal tumor of the adrenal cortex, producing the so-called adreno-

genital syndrome which comes on after puberty. At the age of seventeen her changes could go with a disordered pituitary function, and the signs are not classic of a type of adrenal tumor that comes on after puberty or before puberty. I see no way to include or exclude these possibilities. We have no index from the laboratory procedures recorded. I think this girl's death was due to progressive failure of the lungs, and it got to the point finally where she did not have enough respiratory exchange to survive.

Did she have some disease in the coronary arteries? You will recall that later in the history it says that she suffered from precordial pain which was pounding in character and located over the apex despite the previously normal electrocardiogram. I assume that the electrocardiogram was taken before that pain, although the record is not clear on that point. One wonders about coronary occlusion with myocardial infarction as a terminal episode. This form of accident in kyphoscoliotics is unusual, in fact, it is rare. The patients usually die and at autopsy the heart is found to be hypertrophied chiefly in the right ventricle and even in the right auricle, and yet seldom do they have signs of coronary-artery disease and likewise seldom, if ever hypertension, although a few have been described in which the hypertension is present in addition to a pulmonocardiac syndrome.

I can add very little to this discussion. Perhaps you can, Dr. Aub. You saw her on the wards, and I think I have covered the possibilities that I can see in this case.

DR CHESTER M. JONES: Probably she had been more or less anoxic and increasingly so for quite a few years. That condition was present during puberty. Might not that in itself have been sufficient to account for the sexual immaturity and incomplete growth?

DR CHAPMAN: I do not know how one could tell, but that is a fair statement. In general, kyphoscoliotic patients who begin the deformity early in life continue to be immature, without great sexual development. It would be a possibility just as a matter of general nutrition and general metabolic processes being lowered, and the hypogonadism being a part of it. On the other hand, we have seen these patients come through life and bear children and seem quite normal sexually, or they have no such stigmas of endocrine dysfunction as this patient had.

DR TRACY B. MALLORY: Have you anything to add, Dr. Aub?

DR AUB: No. I agree with Dr. Chapman. We thought that the hypogonadism might be due to prolonged anoxia and cyanosis, but the sexual immaturity we blamed on the pituitary body, otherwise we reasoned the way Dr. Chapman did.

DR LERMAN: When she came on the ward she was a malnourished, underdeveloped pathetic

creature, very orthopneic and dyspneic. The picture of kyphoscoliosis was complicated by the neurofibromatosis which involved the superior mediastinum and the right chest, and produced superior mediastinal syndrome — marked distention of the neck veins and facial edema. It was our impression that the underdevelopment of the sex activity was related to the combination of anoxia and malnutrition.

DR MALLORY: Have you anything to add from the surgical point of view, Dr. Scannell?

DR J. GORDON SCANNELL: She was seen in the Thoracic Clinic with the question of possible superior mediastinal syndrome. Obviously nothing could be done.

DR LERMAN: It was our impression that the kyphoscoliosis developed probably from progressive paralysis of the intercostal nerve as it grew. The kyphoscoliosis had been present for many years.

#### CLINICAL DIAGNOSES

Pulmonocardiac failure  
Neurofibromatosis  
Superior mediastinal syndrome

#### DR CHAPMAN'S DIAGNOSES

Multiple neurofibromatosis, invasive type  
Kyphoscoliosis, left-sided  
Pulmonocardiac failure  
Androgen-producing tumor of adrenal gland

#### ANATOMICAL DIAGNOSES

*Neurofibrosarcoma, with invasion of right innominate vein and superior vena cava*  
Superior-vena-cava obstruction  
Left dorsal scoliosis  
Pulmonary atelectasis  
Hypogonitalism  
Hyperplasia of adrenal glands

#### PATHOLOGICAL DISCUSSION

DR MALLORY: At post-mortem examination a very large tumor was found in the axilla and upper mediastinum on the right side. It was very difficult in the midst of the multiple lobules of the tumor to identify normal structures. We were unable to identify the vagus or the phrenic nerves. The carotid arteries passed through the tumor and were apparently uninvolved except perhaps by pressure. The internal jugular vein could not be identified, and the innominate vein appeared to be completely occluded by a mass of tumor tissue, which dangled down the superior vena cava to within about a centimeter of its mouth into the auricle. The brachial plexus was unrecognizable in the midst of the tumor, and there was enough tumor within the thoracic cage to have caused extensive collapse of the right lung. The heart was quite small, as were

in the morning. There was no history of chills, fever or weight loss.

On physical examination the patient was poorly developed, orthopedic and markedly kyphoscoliotic. There were small plaques of pigmentation over the arms and trunk, with a marked area extending from the anterior axillary line at the level of the nipple extending along the medial surface of the right arm and involving the axilla. A firm, smooth, fixed mass, 15 cm in its longest diameter, was present in the right supraclavicular area. There were small, shotty nodules in the right axilla and beneath the skin along the posterior axillary line. The superficial veins of the neck on both sides were distended, and the veins of the right hand failed to empty on full elevation. The blood pressure was 110 systolic, 80 diastolic, in both arms. The left border of the heart reached the left anterior axillary line. The temperature, pulse and respirations were normal. There was extreme weakness and areflexia in the right upper extremity. There was marked sexual underdevelopment. An electrocardiogram was normal. An x-ray examination of the chest was reported as follows: "There is marked, severe kyphoscoliosis of the dorsal lumbar spine so that the heart is on the right side of the thorax. Size and shape of the heart cannot be determined because of the severe deformity. There has been partial resection of the right upper ribs. A soft-tissue tumor is present over the dorsum of the right side of the chest." Urinalysis was negative. Blood examination showed a hemoglobin of 12.5 gm., and a white-cell count of 11,000, with a normal differential.

While in the hospital she developed rather severe precordial pain, which was pounding in character and located over the apex. There was very little that could be done for this girl except to supply sedation. On the eighth hospital day while she was sleeping at night it was noted by the nurse that respirations had stopped but the pulse was still present. Resuscitation measures were of no avail.

#### DIFFERENTIAL DIAGNOSIS

DR EARLE M. CHAPMAN: May we see the x-ray films?

DR JOSEPH HANELIN: There is an extremely severe spinal deformity, rather marked kyphoscoliosis or perhaps mostly scoliosis. The heart is just visible within the right thorax. There have been resections of the right upper ribs, and some rib regeneration has taken place. There is no obvious explanation for the scoliosis in the way of any structural or bony abnormality. There is evidence of a soft-tissue tumor in the right side of the thorax. There is a mass in the region of the right axilla. In the lateral view of the chest, which includes a large part of the patient, the abdomen appears to be somewhat protuberant. There is soft-tissue density present, with a lobulated appearance, which is observed to extend through the dorsal aspect of the

thoracic wall. I cannot be certain that this lesion is within the thoracic cavity, although this is a general situation and cannot be interpreted particularly without stereoscopic films because of the marked deformity.

DR CHAPMAN: May I ask if you see any area in the bony structure that suggests metastatic or destructive lesions?

DR HANELIN: No, I do not.

DR CHAPMAN: Do you see any lesions in the vertebral column?

DR HANELIN: No, I see no lesions at all in the vertebrae.

DR CHAPMAN: Is this a right dorsal kyphoscoliosis?

DR HANELIN: It is to the left.

DR JOSEPH AUB: May I add some information that Dr. Chapman ought to have? The patient had extreme cyanosis of the face and really had an enormous amount of dyspnea, which I do not think the record makes clear.

DR CHAPMAN: From the evidence at hand it seems to me that this girl suffered from two diseases, either one of which alone would have brought about her death, and certainly both together have done so. The first is that she had multiple neurofibromatosis of the invasive type, diagnosed histologically here in this hospital twelve years before death. Then on top of these tumors that no doubt were multiple, she had an increasing deformity of the chest, which we are told was a left kyphoscoliosis compressing the lungs and the soft tissues within the chest to the point where the vital capacity was greatly diminished. Life was a battle. She was struggling to live in the face of great diminution of the pulmonary reserve, and she must have had what I once called pulmonocardiac failure.<sup>1</sup> The interference with breathing, the cyanosis and the description here indicate that there was also occlusion of venous return in the superior mediastinal region. One would think that the tumor produced a superior mediastinal syndrome more marked on the right than on the left according to the description. Beyond that I think any remarks are purely speculative as to what might be found at autopsy. I think, however, the description of the hypogonadism and the statement of the sexual underdevelopment warrant a few remarks. I would like to have information, for instance, whether or not the 17-ketosteroids were determined. I judge they were not done.

DR JACOB LERMAN: No.

DR CHAPMAN: There are perhaps androgen-producing tumors of the adrenal glands that could produce some of the signs present. One wonders if neurofibroma was present in the adrenal area or if one or both of the adrenal glands were involved in this type of tumor. One wonders if she had some other type of hormonal tumor of the adrenal cortex, producing the so-called adreno-

intestinal tract for three or four months, with one massive hemorrhage

Physical examination helps me very little, and the laboratory studies add little, at least to my interpretation of the problem

We might look at the x-ray films. The barium enema was done to explain the symptoms of abdominal cramps and distention and is reported as negative. The chest films were reported negative also, although on looking at them I wondered if she had dilatation of the great vessels.

DR JAMES J. McCORT: It is difficult to say much about the esophageal lesion on the single outside film available and without being able to fluoroscope the patient. On the film available we find that the proximal esophagus is dilated. This terminates in a narrowed area 3 cm in length. Below this is a fairly large hiatus hernia within which the rugal folds have the appearance of gastric mucosa. There is a suggestion of a shelf defect on the upper posterior margin of the narrowed zone in the lower third of the esophagus. The edge of the narrowed area is slightly irregular, it may be slightly nodular, but this is hard to tell, since there may be mucous flecks mixed with the barium. The lower margin does not show a shelf defect. There is possibly a soft-tissue tumor of the narrowed segment, but this cannot definitely be determined on the one film available. The remainder of the stomach and the duodenum do not show any abnormality.

DR SCANNELL: I wondered about the area that you agree is suggestive of a shelf. I am interested that you agreed that the duodenum, without palpation I realize, was normal. The presence of a duodenal ulcer might be an additional red herring.

DR McCORT: We do not have sufficient films to determine whether it is a persistent shelf defect. The lungs are clear. The heart is not enlarged. There is slight tortuosity of the aorta.

DR ALLAN M. BUTLER: Why could they not do fluoroscopic studies?

DR SCANNELL: These are outside films, and that is all the evidence we have.

DR RICHARD H. SWEET: The patient had an adequate study before entry to this hospital, and we thought it would be redundant to repeat it here.

DR BUTLER: That is a very satisfactory explanation.

DR SCANNELL: In this case of course we know that she had a diaphragmatic hernia, and the question is whether or not that would explain all her symptoms. One might suppose that it was incarcerated, and incarceration is certainly associated with bleeding and it can explain the esophageal obstruction. One can assume that it was the diagnosis and sufficient indication to warrant surgery on the basis of bleeding and obstruction, which are disabling. However, we are suspicious because of the change in character of the symptoms and because of the x-ray picture, which on the films avail-

able, is not that of an entirely smooth narrowing of the lower end of the esophagus. It is certainly true that we do not have to make a diagnosis of cancer because hiatus hernia is frequently associated with a good deal of esophagitis and benign stricture of the lower end of the esophagus. I do not know the exact number of cases, but the latter are frequently associated with infradiaphragmatic disease in the nature of a duodenal ulcer, or possibly disease of the biliary tract and, therefore, it is a tenable diagnosis in this patient. A diagnosis of benign disease would be all right if we could agree that it was smooth narrowing and even better if we could demonstrate a small, benign-appearing ulcer. But in any event we would have to visualize this area to satisfy ourselves whether or not carcinoma were present. I think that the question of a dilated and tortuous aorta encroaching on the hiatus is a theoretical possibility but most inadequate to explain the symptoms. An unusual lesion in this region might be lymphoma, which I assume may occur here, although I have never seen one, and specific or nonspecific inflammation in the nature of syphilis, but there is no evidence to make that diagnosis.

Therefore, I come back to whether or not this patient had a carcinoma in the esophageal hiatus hernia, and I am inclined to think that she had, in spite of the fact that she had a little dilatation of the esophagus, which she may have had with her hiatus hernia over the years and which, therefore, certainly does not rule out carcinoma. I am basing it chiefly on the fact that she had changes in her symptoms in a lesion that she had had for many years—also, on the x-ray picture, which first of all, I gather, is suggestive of a soft-tissue mass, although that could be omentum or something in the hiatus hernia, and secondly, is suggestive of an irregular narrowing of the lower end of the esophagus. Therefore, on the eighth hospital day this was either visualized through an esophagoscope or, if the patient was a good risk, exploration carried out for sufficient indications even disregarding the suspicion of cancer. But I think we are justified in making a diagnosis of probable carcinoma of the lower end of the esophagus.

DR TRACY B. MALLORY: Dr Sweet, will you tell us your clinical impression?

DR SWEET: There are several very interesting aspects to this case from the standpoint of the history as well as the findings at operation, one of which is that in my experience with carcinoma of the esophagus massive hemorrhages are exceedingly rare. They occur in carcinoma of the stomach, but I do not recall any from carcinoma of the esophagus. I have encountered one case of lymphoma of the esophagus. Although lymphoma in other parts of the gastrointestinal tract may cause massive bleeding, that particular patient had none.

Another thing about the history that Dr Scannell did not have the benefit of is that she had improved

all the other organs, and there was no evidence of right-sided heart hypertrophy or dilatation of the right auricle. We found no passive congestion of the liver, spleen or kidneys, such as one might expect to find with kyphoscoliotic heart disease. I do not think we can give a dogmatic opinion in this regard. To what extent this tumor of the vena cava may have been responsible for the cardiac symptoms, I do not know. It came so close to the auricle that, with slight change in posture, it is not inconceivable that it could have dipped into the auricle at times. It was quite evident that death was sudden because the liver showed the marked glycogenation that one ordinarily sees in patients who die suddenly with an acute coronary attack or pulmonary embolism. The spine showed no disease of the bone or intervertebral disks, and the scoliosis, I am sure, was functional rather than structural. The uterus was quite small and almost infantile in dimensions. The ovaries were small and showed only slight activity. There were a few small ova and graafian follicles but almost no scars of corpora albicantia. The pituitary body was small and grossly normal. The adrenal glands, in contrast, were quite large, probably slightly larger than normal, but otherwise not remarkable. From their histologic appearance I would expect excess rather than decrease of the adrenal function.

DR AUB: How about the pituitary body?

DR MALLORY: It appeared small but otherwise normal.

DR CHAPMAN: I am intrigued by what you said about the size of the adrenal glands in proportion to the other endocrine glands, and you are not able to estimate of course the degree of function from observation histologically.

DR MALLORY: No.

DR CHAPMAN: It is of considerable interest that Cahill<sup>2</sup> in a recent article reports that the most frequent cause of changes from excess androgen is bilateral adrenal hypertrophy and that "with the exception of survival time there is often no difference between the symptoms of bilateral adrenal hypertrophy and unilateral tumor."

#### CASE 34462

##### PRESENTATION OF CASE

A fifty-seven-year-old woman entered the hospital complaining of attacks of heartburn, distention, indigestion and abdominal cramps, which had been present for a number of years.

In the four-year period prior to admission these symptoms had all increased in severity. In addition

she recently had palpitation, regurgitation of food and a sensation of food sticking in her chest. Walking relieved the symptoms. The discomfort and heartburn always followed meals. X-ray studies done elsewhere four years previously revealed a diaphragmatic hernia. In the three or four months prior to admission she had felt much weaker than usual and had black stools. The hemoglobin had repeatedly been found to be low. There was one episode when she became pale and went into shock and the hemoglobin dropped rapidly. This was treated by transfusion. There had been no weight loss.

On physical examination the heart was not enlarged. The chest and abdomen were normal.

The temperature, pulse and respirations were normal. The blood pressure was 120 systolic, 65 diastolic.

Laboratory examination revealed a normal urine and a guaiac-positive stool. The hemoglobin was 11.8 gm., and the white-cell count 13,000, with a normal differential. There was moderate variation in size of the red cells, platelets appeared slightly increased, there was no achromia. A chest x-ray film and barium enema were reported negative. A gastric series was done just prior to admission here. These outside films were interpreted here, without a fluoroscopy being done at this hospital, as showing a hiatus hernia and a smooth narrowing in the distal esophagus over a distance of 3 cm., with dilatation proximal to this point.

On the seventh hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR J. GORDON SCANNELL: The problem boils down to that of a fifty-seven-year-old woman who had symptoms pointing to the esophagus. They were symptoms of irritation, obstruction and bleeding. Looking first at the historical evidence, I would consider the following to be of significance. First of all, there was increase in symptoms over a relatively short period, four years. "Recently," which is not defined, there were palpitation, regurgitation and esophageal obstruction. So we wonder if she did not have the change in gastrointestinal symptoms, a change that raises the question of new growth in the gastrointestinal tract or any system of the body. She apparently had heartburn for a good many years, as well as distention and abdominal cramps. The latter are hard to explain on the same basis as heartburn, a symptom of esophageal irritation. Another bit of historical evidence is that four years before admission a diagnosis of diaphragmatic hernia was made, which apparently did not raise the suspicion of cancer. We assume, therefore, that some change had taken place in the x-ray picture. Furthermore, there was significant blood loss through the gastro-

## CONCERNING THE DOCTOR DRAFT

THERE is good reason to believe that early in 1949 Congress will debate an amendment of the Selective Service Act to remedy the shortage of physicians in the newly expanded armed forces. What the public reaction will be, both medical and lay, remains to be seen, but already cries of distress and charges of discriminatory legislation are being faintly heard in medical circles. Although it is too soon to pass judgment on legislation not yet born, it may be permissible to indulge in a little basic thinking on some of the issues underlying any draft of doctors.

For example, it is well to bear in mind Congress's purpose in undertaking this postwar expansion. Primarily it is to put teeth into its belated efforts

to prevent World War III, and failing that to give the kind of civilization in which we all believe a reasonable chance for survival in what would amount to a war of extermination—at least of ideologies. These would appear to be objectives to which only our enemies could take reasonable exception but as the country has already learned to its cost no objectives however greatly desired, are attained by wishful thinking.

The magnitude of the stake must never be forgotten. By now it should be clear to everyone over twelve years old that if another world war is not prevented there will be no question of seizing grandpa's musket from over the fireplace and hastening to Concord or Lexington. Nor will it be simply a matter of providing medical officers for the armed forces, by draft or otherwise. Every man, woman and child will be involved, and there will be no time for claiming constitutional rights, because the very existence of constitutional government will be in the balance.

But we have not come to such a pass yet, and, please God, with wisdom and resolution we shall not come to it. Congress's contemplated action will concern chiefly doctors who were trained under ASTP and V-12 at Government expense but were unable to complete their term of active duty owing to the sudden (and as it now seems, premature) demobilization of the country's military force. If they should be required to complete their contract by a few months of peace-time service, it would seem too reasonable a sacrifice to be fairly resented.

While one indulges in basic thinking, it may be well also to contemplate the alternative method of enrollment for service in time of public need. The volunteer system, if system it may be called, may have the advantage of avoiding compulsion, but it has also certain glaring faults. It is unfair. It rewards the shirker, the parasite and the self-seeker while it penalizes the willing, the conscientious and the ready. Most citizens are glad to do their share of the dirty work so long as everyone else is doing his, but they dislike being played for suckers. Its second obvious defect is inefficiency. There can be no assurance that the person who volunteers is qualified, or even needed, for the job. Finally the volunteer system has been and still

considerably in the past two months as manifested by the facts that she had stopped bleeding and she had less pain. The symptoms were not progressive the way they are almost invariably in carcinoma. In quite a large series of cases of carcinoma of the lower end of the esophagus and cardia that we have operated on here, I do not recall the exact figures, but approximately 13 per cent arose in this particular type of case in which there was a short-esophagus type of hiatus hernia in which there probably had been, or might have been, considerable esophagitis, ulceration and fibrotic stricture. We were, therefore, prepared in this patient to find either a carcinoma or an esophagitis.

#### CLINICAL DIAGNOSES

Peptic ulcer of esophagus in hiatus hernia  
Chronic lymphadenitis

#### DR. SCANNELL'S DIAGNOSES

Carcinoma of esophagus  
Diaphragmatic hernia

#### ANATOMICAL DIAGNOSES

*Peptic ulcer of esophagus*  
*Diaphragmatic hernia*

#### PATHOLOGICAL DISCUSSION

DR. SWEET: At operation the lesion was found to be quite characteristic of esophagitis. The peri-esophageal tissues in the mediastinum, as they usually are in that condition, were very much thickened. Dissection of the esophagus was difficult,—it is always more difficult in that lesion than it is in carcinoma,—and there was evidence of reaction all the way up the mediastinum as far as I pursued the esophagus. The area where one can see narrowing on the x-ray film was very firm but not so firm as carcinoma would be. It felt rather rubbery. The herniated portion of the stomach was not particularly unusual except that it was adherent, and the majority of these hernias are not unless there is some interference with the blood supply from an incarceration. I think she had had a lot of mediastinitis. After the esophagus

and stomach had been dissected free from the surrounding tissues it was possible to reduce the stomach below the diaphragm. In other words, this case was characteristic of the majority of cases of hiatus hernia. The shortness of the esophagus is more apparent than real. A true congenitally short esophagus is very unusual, but it does occur. Because of the lesion in the lower end of the esophagus, I chose to do a resection.

DR. BUTLER: Would a fluoroscopic examination have helped to make this diagnosis?

DR. SWEET: It was done at the time the films were made, but I do not believe it helped in this case.

DR. MALLORY: The resected segment consisted of the lower 3 or 4 cm. of esophagus and approximately equal portions of the cardia of the stomach. Just above the junction of the esophagus and stomach was an area of shallow ulceration from which the mucosa was completely denuded. Histologic examination of that area showed a fibrinoid membrane of the type that we characteristically see in active peptic ulcer. Peptic ulcers of the lower end of the esophagus are unusual but not extremely rare lesions. I believe that was the etiology of the ulcer in this case.

DR. SWEET: It looked to me on examining the gross specimen as we resected it as if the ulcer was completely annular. I could not see any normal mucosa whatever.

DR. MALLORY: There was no mucosa of any significance.

DR. SWEET: Do you think that these peptic ulcers in the lower end of the esophagus usually occur in the extension of gastric mucosa that we so often see in the lower end, or do you think they frequently occur in the mucosa, which is characteristic of the esophagus itself?

DR. MALLORY: Judging from the literature usually it is possible to show that there was extension of the gastric mucosa into the esophagus in the majority of these cases. This is not clearly evident here because of the complete denudation of the mucosa.

DR. SWEET: I have a distinct impression that the majority of these ulcers occur in upward extensions of the gastric mucosa, although they are actually in the esophagus.

not be necessary to maintain the blood and tissue concentrations continuously at effective levels to attain a cure. Nevertheless, the most rapidly effective method of treatment, except in certain special circumstances, is still to repeat injections at such frequency as to maintain the tissue levels continuously in excess of the concentration that kills organisms at the maximal possible rate.

If Eagle's thesis is correct, the therapeutic activity of a given dose of penicillin depends primarily on the total length of time for which it remains at bactericidal levels, with particular emphasis on the time for which it is present at the maximally effective concentration in addition to the time required for the organism to recover from the drug and effectively resume multiplication. The enormous differences observed in the curative penicillin doses when either the number of injections or the interval between them is varied should then rest primarily on the total period of effective penicillin action. Conversely, different schedules of treatment that have the same biologic effects should provide effective levels for the same total period, irrespective of the total curative dose used.

Eagle has carried out many experiments in support of his contention. In the meantime, a certain amount of evidence had accumulated from other sources to indicate that frequent doses may be unnecessary. Thus, it has been shown that the 100 per cent curative daily dose of penicillin for pneumococcal infections of mice is the same whether two injections are given daily every twelve hours or eight injections every three hours.<sup>2</sup> In streptococcal infections in mice, the daily penicillin dosage given in a series of small equally spaced amounts was no more effective than equivalent amounts given in one or two doses a day.<sup>3</sup>

In the treatment of human cases of pneumonia, likewise, small doses at rather long intervals were first used successfully in the earliest clinical trials by Tillet et al.<sup>4</sup> More recently, doses of 300,000 units in aqueous solution given every twelve to twenty-four hours have been used successfully at the New York Hospital,<sup>5</sup> and similar dosage schedules employing large individual doses of aqueous penicillin one to three times a day are being practiced in a number of other clinics. In one of the large Boston hospitals a dosage of 100,000 units

of aqueous penicillin every eight hours has been used for the treatment of most cases of pneumococcal and streptococcal infections for some time. In a series of cases of pneumococcal pneumonia recently reported by Price,<sup>6</sup> patients who received large doses of penicillin in aqueous solution twice daily responded as favorably as those who received the same total dosage at more frequent intervals. Of course larger and more frequent doses are required for infections with more resistant organisms, such as many staphylococcal infections and subacute bacterial endocarditis. No doubt the patient will appreciate the longer intervals between the injections, which should also serve to reduce somewhat the burden on the nursing staffs.

#### PUBLIC HEALTH IN INDIA

THE Government of India Information Services in an Independence Anniversary Review points out some of the difficulties India is encountering in her efforts to improve public health. The report also indicates the determination with which the new Government is attacking its problems, and augurs well for an eventual successful solution of them.

Many of the problems, of course, are of an emergency nature and are concerned with the unsettled condition of the country and the mass movements of population between India and Pakistan. Huge refugee camps have required medical relief, the camp at Kurukshetra having at one time accommodated 300,000 refugees under canvas for whom a thousand-bed hospital was established by the director-general of Health Services. Campaigns of inoculation and vaccination against cholera, smallpox and tuberculosis have been organized nearly 40,000 BCG vaccinations having been done up to the end of June, 1948. Periodic delousing operations have been carried out in this city of tents,

is being tried almost to the point of bribery, but without success

It need not be concluded on that account that the failure to meet military quotas by voluntary enrollment means a tendency on the part of the profession to shirk its duty. Rather, it may be considered a reflection of the ordinary man's desire for fair play and the thoughtful man's appreciation of the importance of meeting his country's vital undertakings with an equal efficiency of action. It is earnestly believed that any future legislation that is fair, efficient and necessary will be approved by the medical profession regardless of the personal sacrifices it may demand of individual physicians.

### PENICILLIN DOSAGE AND BLOOD LEVELS

THE problem of dosage of penicillin at present is considerably different from what it was when the antibiotic first became available and it was both scarce and expensive. The general tendency is to use amounts that are far greater than those that could be deemed necessary in most infections by any consideration of the sensitivity of the causative organisms and by the blood levels attainable. The purified crystalline preparations now available are relatively nonirritating, so that aqueous solutions in sterile water or physiologic saline solution in concentrations up to more than 100,000 units per cubic centimeter can be given with a minimum of discomfort. Doses of 100,000 units or more are often used every two or three hours in the treatment of acute bacterial infections due to such organisms as the pneumococcus and the hemolytic streptococcus, which in most cases are sensitive to between 0.01 and 0.08 units per cubic centimeter.

Considerable early experience has shown that doses of 10,000 to 15,000 units every three or four hours are quite adequate for most of these cases. Furthermore, recent observations by a number of experienced workers and some of the earlier results have indicated that cures may be effected in cases of lobar pneumonia even when intervals of eight to twelve hours are permitted each day during which no injections are given. This is true in spite of the fact that penicillin activity cannot be demonstrated in the blood during the greater part of this interval.

Eagle<sup>1</sup> very ably discussed the significance of the penicillin blood levels at last year's meeting of the American College of Physicians. A brief summary of his speculations, which are based on a considerable amount of experimental evidence, should be of interest.

Eagle argues that the penicillin blood level is of significance only so far as it provides a rough measure of the concentration in the tissues at the site of the infection. The curve of the tissue levels after an injection of penicillin is important and may be expressed in terms of three time periods: the length of time for which penicillin is present at maximally effective concentrations that kill the organism at the fastest possible rate, the time for which penicillin is present at somewhat lower concentrations that are more slowly bactericidal, and the period after the penicillin has fallen to concentrations lower than those that kill bacteria *in vitro* but during which the organisms continue to die in the body at a rate faster than they multiply. This continuing death of organisms may be due to penicillin that persists in the tissues longer than it does in the blood, or the organisms may be killed by lower concentrations of penicillin in the body than they are in the test tube, owing perhaps to the participation of the body's defenses, or the organisms that have been exposed to penicillin may recover from its deleterious effects slowly and during a temporary period of retarded multiplication they may be disposed of by the defense mechanisms of the host. Whichever the cause may be, the period of gradually disappearing penicillin activity provides a margin of safety in that the blood and tissue penicillin levels may be permitted to fall below those that are significantly bactericidal in the test tube without affecting the outcome of treatment.

Large injections of penicillin are more effective than small injections, according to Eagle, not because they provide higher absolute levels of penicillin, but because they provide the effective concentrations for longer periods of time. More organisms are thus killed by each injection, and fewer survive to remultiply in the interval between injections. That interval may then be prolonged because with fewer surviving organisms less harm is done by a penicillin-free interval during which the organisms multiply. In general, therefore, it should

Further attempt was made to provide for elasticity in the charges for certain operations or other services which seemed to evoke more than average contention by listing the minimum and maximum amounts considered equitable. These items bear the notation "AA," which indicates that the fee for the given service is to be determined by arbitration and agreement between the Veterans Administration and the Medical Society concerned.

May I reiterate that the Veterans Administration Fee Schedule Format is in no sense to be construed as an arbitrary or National Fee Schedule. Furthermore it is subject to periodic review and such modification as conditions may indicate.

If it meets with your approval I would appreciate it very much if you could possibly arrange to publish this as an open-letter in the *Journal of the American Medical Association*. I should like this to reach all the physicians throughout the country and I know of no better way to do it than through the *Journal*.

PAUL B MAGNISON, Chief Medical Director

Veterans Administration  
Washington 25, D C

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### RICE DIET

The rice diet is at present in common use for the relief of hypertensive states. Patients upon diets prescribed for such therapeutic purposes not infrequently develop nutritional deficiencies as a result.

The Massachusetts Department of Public Health, therefore desires to call attention to deficiencies

not only in protein but also in many of the minerals and vitamins. Such a diet when calculated shows itself to be adequate in vitamin A only provided prunes, apricots or peaches are used daily, high in vitamin C when orange and grapefruit juices are used, and low in calcium, protein and components of the vitamin B complex, particularly riboflavin. Sufficient iron is not supplied unless apricots and prunes are consumed regularly. Some physicians include 8 ounces of prune juice daily to meet the need of iron. If pineapples, apples, grapes (or their juices) or pears and bananas are substituted, in whole or in part, for the above fruits the vitamin A, ascorbic acid and iron will fall below recommended levels.

The following menu is an example of a day's diet planned on Kempner's basic diet, and Table 1 shows how a day's rice diet, with these fruits, compares with the day's needs for a moderately active man.

#### BREAKFAST (7 A M)

1 cup orange juice  
2 cups boiled rice  
22 grapes

#### LUNCH (11 A M)

2 tablespoonsful honey on  
3 cups rice  
1 cup orange juice  
2 fresh peaches

#### SUPPER (4 P M)

Rice crown  
2 apricots  
(2 cups rice  
4 stewed apricot halves)  
1 cup prune juice  
1/2 cantaloupe

#### NIGHT (8 P M)

1 cup orange juice  
3 plums

TABLE 1 Daily Requirements of a Moderately Active Man Weighing 70 kg

DAILY INTAKE	CALORIES	PROTEIN	CALCIUM	PHOSPHORUS	IRON	VITAMIN A	THIAMINE CHLORIDE	ASCORBIC ACID	RIBOFLAVIN
		gm	gm	gm	mg	I U	mg	mg	mg
Ordinary diet	3000	70.0	0.8	0.88	12.0	5000	1.5	75	2.0
Diet with white rice	1874	51.6	0.337	0.587	11.5	15,870	1.13	368	0.54
Diet with brown rice	1909	28.8	0.421	1.175	24.1	13,870	1.78	368	0.64

of the unsupplemented rice diet. The rice diet frequently prescribed for hypertension may bring about nutritional deficiencies in certain patients with previously poor nutritional status if the diet is continued for more than a few weeks without added minerals and vitamins.

The basic rice diet outlined by Kempner in the *North Carolina Medical Journal* (February, 1945) consists of 400 gm of rice fruit, fruit juices and sugar. It furnishes about 2000 calories, 20 gm of protein, 0.2 gm of chloride and 0.15 gm of sodium. The following minimal doses are recommended: vitamin A, 500 units, vitamin D, 1000 units, thiamine chloride, 5 mg, riboflavin, 5 mg, niacinamide 25 mg, calcium pantothenate, 2 mg, and ferrous sulfate, 0.6 mg. Without this supplementation the meals of rice and fruit tend to be low

Both brown and white rice are recommended in rice diets. The above calculations do not take into account losses of thiamine, riboflavin and niacin that result from washing of rice. Such losses vary according to the rigor of the washing. They may be as high as 43 per cent of thiamine, 25 per cent of riboflavin and 23 per cent of niacin. Further losses result in cooking, but the most serious losses are due to washing. This will not be of importance if the diet is supplemented adequately, but may be of considerable consequence if the patient on the very restricted form of the diet makes a poor choice of fruits and overwashes the rice during preparation.

This particular day's diet includes both prunes and apricots and so provides a good amount of iron. The yellow foods, peaches, apricots, oranges

and fly and mosquito control measures have been developed and enforced

In addition plans for more permanent programs are being initiated. Health legislation has been passed and the reorganization of Delhi hospitals has been outlined. Steps are being taken for the establishment of health centers in Delhi Province and elsewhere. A program is under way for the improvement of medical schools and research institutes and for the development of postgraduate training.

The Health Ministry has moreover found the time and personnel to participate in various international conferences that have been held during the year. Delegations were sent to the International Cancer Research Conference in St. Louis in 1947, to the International Leprosy Congress in Cuba, to the International Congress on Tropical Medicine and Malaria in Washington last May, to the BCG Congress in Paris and to the first World Health Assembly at Geneva.

A tuberculosis institute is to be established in connection with the University of Delhi, and increased Government grants have been provided for the Tuberculosis Association of India. The activities of the Malaria Institute of India have resulted in further reduction in the incidence of malaria in Delhi.

Mother India, with her new-found freedom, is in fact fast becoming a modern mother. She has taken on the new look and has every intention of joining the other forward-looking mothers of the world.

### THE JAPANESE MEDICAL JOURNAL

WE WELCOME into the field of medical journalism *The Japanese Medical Journal*, of which the first two issues have come to hand, those of February and April, 1948. *The Japanese Medical Journal*, in English, is the official publication of the National Institute of Health of Japan, under the managing editorship of Hidetake Yaoi. Its contents, selected from papers submitted by all research institutions throughout Japan, may be considered, as the editor states, to be representative of the type of work being carried out in that country.

This journal, in a medical sense, is the first fruit of a reconstituted Japan. May it be representa-

tive of a new life and a new outlook, a step toward membership in a new society of nations that will look only in the direction of peace and the betterment of mankind!

### ROBERT N NYE MEMORIAL FUND

The Nye Memorial Fund has recently been increased by an additional gift of \$1000 from a previous donor.

### MASSACHUSETTS MEDICAL SOCIETY

#### VETERANS ADMINISTRATION FEE GUIDES

In order to give the subject of fee guidance schedules widespread publicity, the chief medical director of the Veterans Administration has requested that the following letter be reprinted in the various state journals. It first appeared in the *Journal of the American Medical Association*, May 22, 1948.

H. QUIMBY GALLUPE, *Secretary*

Dr. Morris Fishbein  
Editor, the *Journal of the American Medical Association*  
535 North Dearborn Street  
Chicago, Illinois

Dear Dr. Fishbein:

It has come to my attention that considerable misunderstanding has developed throughout the medical profession concerning the establishment of fees for medical services to be paid private physicians participating in the so-called "Home Town Medical Care Program for Veterans." It has been contended that the Veterans Administration has arbitrarily established a Fee Schedule which represents the maximum amount which may be paid for any given service and which is, in effect, a National Fee Schedule. It has also been contended that the various State Medical Societies and other interested groups were not consulted when this Fee Schedule was adopted.

In order to clear up any misunderstanding regarding this matter, it is desired to emphasize that my predecessor, Dr. Paul R. Hawley, had no intention at any time of establishing a National Schedule of Fees, nor do I contemplate doing so. However, the Fee Schedules originally submitted by the various State Medical Societies, when the "Home Town Medical Care Program" was inaugurated, varied so widely in format, terminology, and fees for similar or identical services, that it was deemed advisable to establish a uniform Fee Schedule Format and to set up tentative fees which could be used as a guide by the various State Medical Societies when submitting their proposals for the furnishing of medical care to veterans.

This uniform Fee Schedule Format was formulated by the Professional Group of National Consultants to the Chief Medical Director. This Group, representing the various specialties in medicine and surgery, is composed of eminent physicians from all parts of the country. Tentative fees were set up in the format after a careful analysis of Pre-Paid Medical Care Plan, Workmen's Compensation and Insurance Fee Schedules, and also the Fee Schedules in effect in the various States having agreements with the Veterans Administration. As was to be expected, considerable variation occurred in the Fee Schedules reviewed. The Professional Group of National Consultants made every effort to arrive at fees that were considered to be within reasonable limits and which would, as nearly as possible, allow a uniform provisional fee schedule for use as a guide in facilitating and expediting the preparation of agreements between State Medical Societies and the Veterans Administration.

ticks and so a vicious circle is formed, spreading and perpetuating the disease

In Massachusetts, ticks have been known to spread only tularemia and Rocky Mountain spotted fever. Tularemia made its first appearance in Massachusetts in 1937 in Falmouth, and a total of 17 cases had been reported to the Department of Public Health up to and including 1947. Ten of the 17 cases occurred in the tick-infested area and were attributed to tick bites. On the other hand, Rocky Mountain spotted fever first made its appearance in 1938 in Dennis, 10 cases have been reported, 2 being contracted outside Massachusetts and the remaining 8 in the tick area of the Cape. The problem of tularemia in Massachusetts has recently been discussed in detail in the *Journal*.<sup>2</sup>

Although it is important to attempt to control ticks in Massachusetts because of the possibility of their transmitting certain diseases, the most pressing reason for such control is the fact that they are a trying nuisance. In the southeastern portion of the Commonwealth, every spring and summer, residents and visitors in the area must perform the daily task of inspecting themselves and members of their families for the presence of ticks and must frequently perform the tedious chore of removing ticks from dogs and other pets.

The study was started too late this year to permit much information to be accumulated regarding the control of ticks by sprays. A few experiments have confirmed observations of others that the prevalence of ticks can be decreased by spraying of the grass and bushes in an infested area with DDT. Unfortunately, such a measure is only palliative and probably only affects in a minor way the eventual solution of the problem, because it is feasible to spray only restricted areas that are most frequented by residents and summer visitors and their dogs. Reproduction of ticks is continued because dogs wander into areas of lower prevalence and furnish the blood meals for ticks that will replenish the tick population.

If spraying operations could be supplemented by measures to keep ticks from obtaining their blood meals from dogs, a much more permanent effect could be obtained.

It is expected that the tick study will be continued for the next year or two so that some of these problems can be attacked. Dipping dogs is usually much more effective in getting rid of ticks, but the operation is messy and dog owners will not take advantage of this method of control. A thorough study of the usefulness of DDT, rotenone and other materials in powder form would be useful.

Any assistance that physicians can give to increase knowledge of the geographic distribution of the tick population will be useful in the study. In the August 26 issue of the *Journal*, a questionnaire, which is being used for accumulating information, was referred to. Any physicians who did not fill

out the form are asked to forward it with any information which is available.

## CORRESPONDENCE

### FURTHER DATA ON LOWER-NEPHRON AND MERCURIAL NEPHROSIS

To the Editor: It is believed that the following addendum to my paper on "Acute Renal Insufficiency Due to Lower-Nephron Nephrosis," which appeared in the November 4 issue of the *Journal*, will be of interest.

The pathologic lesion in mercurial nephrosis differs from that of lower-nephron nephrosis in that the proximal segment of the convoluted tubule is chiefly affected. The following case is of interest because, as pointed out by R. Batson and J. C. Peterson, in an article entitled "Acute Mercury Poisoning: Treatment with BAL in anuric states with continuous peritoneal lavage" (*Ann Int Med* 29:278-293, 1948), it is currently believed that "these patients who, not having received BAL therapy within the first few hours, will develop anuria secondary to tubular injury. These patients will ultimately die unless something can be done to provide a temporary means of controlling their uremia until renal function returns."

This case illustrates that the general principles originally put forth by J. P. Peters, A. J. Eisenman and D. M. Kidd, in an article entitled "Mercury Poisoning" (*Am J Med Sc* 185:149-171, 1933) remain sound.

A 48-year-old mechanical engineer (B. C. H. 1298442) accidentally ingested 0.5 to 1.0 gm. of mercuric bichloride on the morning of September 22, after which he had breakfast and then became nauseated, vomiting at first food and then bloody material. Shortly thereafter watery bloody diarrhea began. During the 8 hours prior to hospitalization he vomited five or six times, had at least ten watery, red stools and passed urine several times. On entry there was very mild evidence of shock. The hematocrit was 57 per cent, the hemoglobin 18 gm. per 100 cc., and the white-cell count 28,000. Shortly after admission he received an intravenous infusion of 500 cc. of physiologic saline solution followed by 500 cc. of citrated whole blood. Early the next morning the same quantity of blood and saline solution was administered. Since the hematocrit remained at 50 per cent in spite of this therapy, 1000 cc. of 10 per cent glucose in saline solution was given, after which the hematocrit declined to 44 per cent and the hemoglobin to 15 gm. Shortly after admission the patient voided 200 cc. urine, which gave a  $\pm$  test for albumin, with many casts and occasional white and red cells in the sediment. Nine days later 50 cc. of urine appeared. During the period of anuria the patient received approximately 750 cc. of 15 per cent of glucose in distilled water daily, as well as intravenous injections of an amount of physiologic saline solution or its equivalent as sodium bicarbonate or sodium lactate equal to the output in vomitus or stool.

Forty-eight hours after entry stool examinations were reported as positive for mercury (the patient up till this time had steadfastly denied the possibility of poisoning of any type). He therefore received 1575 mg. of BAL intramuscularly divided into nine equal doses during the next 48 hours. With the omission of all liquids and food by mouth, vomiting ceased promptly. Within a few days there was no further diarrhea. The temperature, pulse, respirations and blood pressure showed no essential change. The blood nonprotein nitrogen rose to a peak of 252 mg. per 100 cc. on the 15th day. The serum sodium remained at approximately 133 milliequiv. per liter. The serum potassium, which was 4.6 milliequiv. per liter on the 3rd day, never rose above 5 milliequiv. The

and the deeper-colored variety of cantaloupe make the diet more than adequate in vitamin A. However, calories, protein, calcium and riboflavin are very low, and wherever diets are low in calcium and protein they tend also to be low in phosphorus. The lowered calorie intake may need attention when an inactive patient returns to active work.

That protein restriction has a beneficial effect in hypertension has not yet been conclusively shown. This protein deficiency of the rice diet is being studied, and in some cases a form of low-sodium milk is in use to compensate for the deficiency of both protein and calcium.

## MASSACHUSETTS TICK SURVEY

JOHN C. AYRES, M.D.,\* AND

ROY F. FEEMSTER, M.D., DR. P.H.†

For many years, the wood tick, officially known as the American dog tick, has been an annual nuisance on Cape Cod and Martha's Vineyard and inland from the South Shore. In recent years, a few cases of such tick-borne diseases as Rocky Mountain spotted fever and tularemia have been occurring in the same area.

The Department was directed by Chapter 36 of the *Resolves* of 1948 to study the problem and seek to find ways by which the nuisance could be abated.

It is important, in connection with this study, to know the geographic distribution of this tick (*Dermacentor variabilis*) as well as any other important species of ticks with which it might be confused.

For the benefit of physicians who might like further information regarding the problem, a brief account of the ticks found in the State follows. Much of this information is taken from a voluminous compilation by Bequaert.<sup>1</sup>

### Varieties

Ticks are divided into two families: the *Argasidae* or soft ticks and the *Ixodidae* or hard ticks. The former are more primitive and less constantly parasitic, produce fewer offspring, feed frequently and at night, do not increase greatly in size when gorged on blood and seldom travel far; the latter are more specialized and more highly parasitic, produce more numerous offspring, and take only one blood meal in each stage but are capable of taking such great quantities that they increase many times in size and weight. The hard ticks possess a horny shield, which entirely covers the back in the male and partially covers it in the female.

### Prevalence

Of the four species of *Argasidae* found in the United States none is present in Massachusetts.

\*Epidemiologist, Massachusetts Department of Public Health.

†Director, Division of Communicable Diseases, Massachusetts Department of Public Health.

On the other hand, several species of the *Ixodidae* are present. These are the common wood or dog tick (*D. variabilis*), which attacks dog and man and which feeds to a large extent in the immature stages on small rodents such as meadow mice, the rabbit ticks (*Haemaphysalis leporis palustris* and *Ixodes dentatus*), which do not attack man but which are often present in large numbers on rabbits and may also be found on meadow larks, quail and other birds, the mouse ticks (*Ixodes scapularis*, *Ixodes muris*), which are rather common on meadow mice, other small rodents and more rarely on rabbits, and other ticks (*Ixodes bruneus*, *I. cookei*, *I. marxi* and *Haemaphysalis chordeilis*), which infest small animals and birds primarily.

*D. variabilis* is the most important one of this group since it is found regularly on dogs and frequently on human beings. It is a three-host tick. The fertilized female drops 2000 to 8000 eggs on the ground. In one or two months the eggs hatch, and the larvae attach themselves to small mammals and engorge for two to eight days. Then they drop to the ground, digest their meal and molt to nymphs. The first winter they usually spend as unfed nymphs. The following spring the nymphs attach themselves to rodents, engorge, drop to the ground, digest their meal and molt to adults. The unfed adults attach themselves to larger mammals, including man, mate, engorge and drop off.

The distribution of ticks in areas depends upon the presence of hosts. The meadow mouse is the principal host of the young forms, and the best "mouse country" is uncut, ungrazed grassland dotted with variable amounts of thickets and shrubs. Beach grass, grassy patches in woodland, and areas denuded in lumbering are also favorable, but ticks are seldom found in forests.

### Ticks As Transmitters of Disease

Ticks have been recognized as transmitters of disease in man and animals since 1893. Many species not only carry disease-producing organisms through several stages of change in form but also transmit them through the eggs to the next generation. They transmit five groups of disease: rickettsial, viral, bacterial, spirochetal and protozoan. In America, ticks have been proved to be transmitters of Rocky Mountain spotted fever, tularemia, Q fever and Colorado tick fever and to cause tick paralysis by a poisonous substance that they produce. Furthermore, in the laboratory they have been shown to be capable of transmitting other diseases, such as encephalitis.

Ticks obtain micro-organisms from their various hosts. These organisms in turn develop within the tick, invading all tissues and passing through all stages finally to the egg. Once the tick is infected it can transmit the disease to other animals, birds, rodents and even man. The newly infected hosts then act as new reservoirs for other uninfected

OBJECT:  
DRAINAGE

In discussing the management of chronic cholecystitis without stones, Albrecht states

"The object of the medical procedure is to assist in draining an infected organ" \*

The specific hydrocholeretic action of Decholin (chemically pure dehydrocholic acid) accomplishes this purpose

Decholin induces bile secretion which is thin and copious, flushing the passages from the liver to the sphincter of Oddi, and carrying away infectious and other accumulated material

HOW SUPPLIED Decholin in 33 1/4 gr tablets Packages of 25, 100, 500 and 1000

serum chloride declined to a low of 68 millicquiv, and the carbon dioxide to 9.9 millicquiv per liter. On the 9th day 50 cc of urine was passed, followed on successive days by 100, 260, 500, 1000, 2000 and 3300 cc. This urinary output was associated with a falling nonprotein nitrogen and a rise in serum chloride and carbon dioxide. With the urine output at 2000 cc the patient was allowed fluids and food freely by mouth and made an uneventful recovery. He returned to work 24 days after the onset of illness.

Since my manuscript was submitted for publication, gastric and intestinal lavage has been successfully employed in the treatment of 7 patients with uremia associated with prostatism, by V. Vermooten and D. M. Hare reported in an article entitled "The Use of Continuous Gastric Lavage in the Treatment of Uremia Associated with Prostatism" (*J Urol* 59:907-919, 1948), and in a patient with anuria and uremia secondary to the ingestion of cleaning fluid by H. H. Marquis and F. P. Schnell as noted in a report entitled "The Treatment of Anuria by Intestinal Perfusion" (*Am J M Sc* 215:686-693, 1948). In this case, no attempt was made to follow the level of serum potassium until cardiac arrhythmia appeared, when it was found to be 1.2 millicquiv per liter, or approximately a fourth normal. Death appeared to have been caused by this extreme hypokalemia.

Chief of Medical Service

Cushing Veterans Administration Hospital  
Framingham, Massachusetts

## NOTICES

### ANNOUNCEMENT

Dr. Carl V. Lendgren announces the removal of his office to 8195 California Avenue, South Gate, California.

### SOUTH BOSTON MEDICAL SOCIETY

A meeting of the South Boston Medical Society will be held on Monday, November 15, at 9 p.m., at the Carney Hospital. Dr. Grantley W. Taylor will speak on the subject "Oral Carcinoma."

### GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held at the Boston Medical Library on Tuesday, November 16, at 8:15 p.m. A symposium entitled "Recent Advances in the Diagnosis and Treatment of Psychiatric Disorders" will be presented, with Dr. Harry C. Solomon as chairman.

#### PROGRAM

Lobotomy Dr. James Poppen  
Current Somatic Therapies in Psychiatry Dr. Milton Greenblatt.  
Psychotherapy Illustrated by dermatologic cases Dr. Lester L. Hasenbush

### SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, November 16, at 12 noon. The speaker will be Dr. William J. Mulligan, who will discuss the subject, "Disorders of Menstruation."

Physicians are cordially invited to attend.

### BOSTON STATE HOSPITAL PSYCHIATRIC SEMINAR SCHEDULE

Psychiatric seminars will be held in the Reception Auditorium of the Boston State Hospital during 1948-1949 on Wednesdays at 12 noon, followed by a staff luncheon at 1 p.m.

#### SCHEDULE

1948

November 17 The Electroencephalogram in Psychiatric Research Dr. Robert S. Schwab  
November 24 The Work of the Psychologist in Relation to Psychiatry Dr. Herbert I. Harris  
December 1 Psychotherapy for Psychosomatic Disorders Dr. Grete L. Bibring  
December 8 Care of the Disturbed Psychotic Patient (To be announced)  
December 15 Teaching Psychotherapy in an Outpatient Department Dr. Bernard Bandler  
December 22 A Theory of Personality Dr. Andras Angyal  
December 29 Mongolian Idiocy Dr. Clemens Banda.

1949

January 5 What Society Should Do for the Alcoholic (To be announced)  
January 12 The Neurological Basis of the Emotions Dr. Stanley Cobb  
January 19 (To be announced)  
January 26 Recent Developments in the Treatment of Epilepsy Dr. Harry Kozol

### BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

A meeting of the Boston Society of Psychiatry and Neurology will be held at the Boston Medical Library, 8 Fenway, on Thursday, November 18, at 8:15 p.m.

#### PROGRAM

Acoustic Tumors Intracapsular removal versus total resection Gilbert Horrax, M.D. Lantern slides (thirty minutes)  
Psychometric Changes after Lobotomy Charles A. Atwell, M.A. (fifteen minutes)  
Sexual Behavior after Lobotomy Julius Levine, M.D., and Harold Albert, M.D. (fifteen minutes)

### NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

A meeting of the Anesthesia Study Committee of the New England Society of Anesthesiologists will be held in the Auditorium of Building A, Boston University School of Medicine, on Tuesday, November 23, at 8 p.m. The chairman will be Dr. Meyer Saklad. There will be a presentation of case reports on morbidity and mortality, followed by a discussion from the floor.

Physicians and medical students are invited to attend.

### BOSTON CITY HOSPITAL HOUSE OFFICERS' ASSOCIATION

The Boston City Hospital House Officers' Association announces the following programs in its evening lecture series.

November 16 Practice Inside and Outside the Hospital Dr. Samuel A. Levine  
November 23 Hypertension as a Disease of Adaptation Dr. Hans Selye, professor and director of the Institute of Experimental Medicine and Surgery, University of Montreal Faculty of Medicine  
November 30 Physiology of the Liver, and Liver-Function Tests Dr. Franklin M. Hanger, Jr., associate professor of medicine, Columbia University College of Physicians and Surgeons and associate attending physician, Presbyterian Hospital, New York City  
These programs are held at 7 p.m. in the New Cheever Amphitheater of the Dowling Building, Boston City Hospital.

All interested persons are invited to attend.

## MEDICAL ASPECTS OF ATOMIC ENERGY\*

SHIELDS WARREN, M.D.†

BOSTON

THE Atomic Energy Commission has been charged by you and your fellow citizens with the responsibility of ensuring that the best use will be made of this new source of energy consistent with the national security as well as with maintaining the secret of the atomic bomb and making it available as a weapon. In such a program medicine naturally has a significant role. There is first the problem of maintaining health of the workers in the varied processes incident to the activities of the atomic-energy program. These hazards range from those of radioactive substances in amounts undreamed of a few years ago to the drab and prosaic fall from a stepladder or the almost routine automobile accident. It speaks well for the foresight, the skill and the industry of those charged with medical responsibility in the Manhattan project days that only two people have been killed by radiation hazards. When we remember that many thousands were exposed for several years to potential but adequately controlled hazards this is a remarkable showing, from the fact that among a handful of people exposed more than twenty years ago to the radium watch-dial paint in New Jersey many times this number of radiation deaths occurred, one can see the progress that has been made.

This progress, like the iceberg, showed but little above the stream of contemporary knowledge in the pre-war days. The patient work of the early radiologists, the biophysicists and the experimental biologists gradually and unobtrusively built up a mass of knowledge on which standards of permissible dosage could be safely built. Today there is less hazard in going into plants of the Commission than there is in crossing downtown streets. The knowledge and patient devotion to duty of the health physicists now maintain safety not only for those within the plants but also for those who might be injured by some accident in the environs of the plant.

Secondly, we have the task of developing ourselves and making it possible for others to develop those forays into intellectual darkness by which new continents of knowledge may be mapped out and developed. To give you some idea of the extent to which work in the field of basic medical and biologic research is being carried on, in addition to millions being spent in the Commission's own establishments, over \$1,300,000 has been allocated in the last six months for fundamental medical and biologic research in medical schools and hospitals.

Thirdly, no program can be better than the personnel by whom it is conceived and executed. This country is faced today with the scarcity of trained scientists that harks back to the waste of manpower that occurred in the last war. War is always wasteful but no country in World War II was as careless as ours of its trained personnel or as shortsighted regarding the scientific needs of the future. To help repair this loss—a loss that in the world of today is more serious than that of many army divisions or battles—the Atomic Energy Commission has established a fellowship program reaching through all the sciences, but because of our particular interests I shall discuss only those having to do with medicine, biology and biophysics. The National Research Council, at the request of the Commission, has established a fellowship program with Commission funds that is available not only for the doctor of medicine and for the doctor of philosophy in biology or basic medical sciences but also for the college graduate. The postdoctoral fellowships are for two years, the predoctoral are for one year but may be renewed. It is hoped that a considerable number of predoctorate fellows will continue on to obtain their M.D. or Ph.D. degree by means of aid afforded them through this fellowship program. This program envisages the training of 100 predoctoral fellows and 75 postdoctoral fellows each year.

Fourthly, the Atomic Energy Commission is providing radioactive isotopes for experimental and therapeutic purposes.

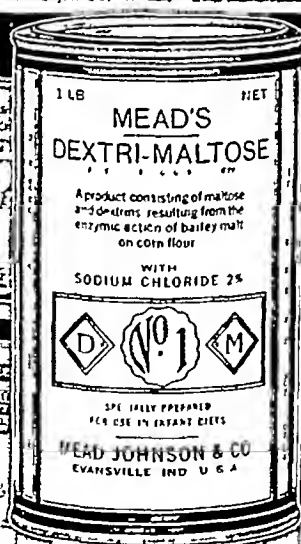

\*Presented at the annual meeting of the Massachusetts Medical Society, May 2, 1948.

†Professor of pathology, Harvard Medical School, pathologist, New England Deaconess Hospital, director, Division of Biology and Medicine, Atomic Energy Commission.

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri Maltose.

## THE CLINICAL CHARACTERISTICS OF EARLY DIABETES MELLITUS

SAMUEL B. BEASER, M.D.\*

BOSTON

CURRENT descriptions of diabetes mellitus vary markedly—as much as 300 per cent—regarding the symptoms of the disease.<sup>1,2</sup> Likewise, there is little exact information about its early course. The present survey of the population of a large diabetic clinic was undertaken to clarify these points.

## METHODS

The records of 500 consecutive patients were examined and 182 with adequate descriptions of the onset of the disease were accepted for study.

TABLE 1 Clinical Features at the Time of Diagnosis

PRESENTING COMPLAINT*	TOTAL NUMBER	PERCENTAGE OF GROUP	PERCENTAGE OF TOTAL
<b>Diabetic group</b>			
Polydipsia	32	49.0	16.8
Polyuria	50	46.0	15.8
Weight loss	50	46.0	15.6
Weakness	35	38.0	15.1
Fruity odor	23	32.0	12.1
Nocturia	9	14.0	7.4
Polyphagia	7	11.0	5.7
Refractive changes	4	6.0	2.1
Headache	2	3.0	1.0
Acroemia	1	1.5	0.5
Drowsiness	1	1.5	0.5
Patients with onsets with one or more of above	65	100	34.0
<b>(Diabetic) complication group</b>			
Pain or definite neuritis†	22	62	11.5
Ulceration	12	35	6.5
Charact.	2	5	1.1
Patients with onsets with one or more of above	36	100	19.0
<b>Casual group</b>			
Onset	15	16.9	7.9
Cardiac condition‡	15	14.6	6.5
Chronic headache	5	5.1	2.6
Intermittent claudication	2	2.5	1.1
Halt examination	2	2.5	1.1
Cerebral retinal thrombosis	1	1.0	0.5
Myelolysis	61	69.0	32.0
Patients with onsets with one or more of above	89	100	47.0

\*Since many patients had more than one presenting complaint the total of both types of onset (150) and presenting complaints exceed that of patients.

†Chief of vulva—scrotal or other skin areas.

‡Symptoms either proved to be due to definite neuritis or carefully investigated to rule out other diseases and subsiding promptly (usually in weeks) after institution of diabetic care.

§Due to bacterial or mycotic organisms and including skin, genitourinary, and feet.

¶Includes angina pectoris, myocardial infarction and congestive failure, arrhythmia, or both.

They had all been followed on the wards or in other clinics and had been referred to the diabetic clinic because of diabetic symptoms or glycosuria. In most cases a complete medical history had been

taken, but an additional diabetic history was elicited. Of these 182 patients, 113 who were found to have had one or more urinalyses prior to diagnosis (usually on morning post-prandial specimens) were investigated in greater detail. Patients with renal glycosuria were excluded from this study.

## RESULTS

Classified according to the types of chief complaint, the patients fell into three groups: "diabetic onset," with diabetic symptoms, "complication onset," with diabetic complications, and "casual onset," with glycosuria alone. It can be seen that the incidence of symptoms can vary significantly, depending on the method of analysis (Tables 1 and 2). However, no one complaint occurred in more than 50 per cent of the patients and fully 23 per cent had no diabetic symptoms (Table 3). The chief complaints comprised only a minority of elicitable diabetic symptoms, individual symp-

TABLE 2 Total Diabetic Symptoms Present, Including Both Presenting Complaints and Those Elicited by Further Questioning of All Patients, Regardless of the Type of Onset

SYMPTOM	TOTAL NUMBER	PERCENTAGE OF TOTAL ONSETS
Weight loss	94	49.5
Polydipsia	72	38.0
Polyuria	69	37.0
Fruity odor	49	26.0
Weakness	46	24.0
Nocturia	44	23.0
Polyphagia	17	9.0
Refractive changes	4	2.0
Headache	2	1.0
Anorexia	1	0.5
Vertigo	1	0.5
Drowsiness	1	0.5

toms being overlooked, as follows: weight loss 64 cases (70 per cent of the total), polydipsia, 40 (58 per cent), and polyuria, 39 (57 per cent).

Table 4 confirms statistically the validity of classifying the complications separately from the symptoms of diabetes. This is further substantiated by the variation of their incidence among the different types of onset (Table 3).

Decompensation of carbohydrate metabolism can be defined quantitatively. Thus, the patients with the diabetic type of onset are in advanced and the others in partial metabolic failure. There is a definite correlation between insulin need and the degree of metabolic decompensation (Fig. 1).

†Partial or advanced decompensation of the diabetes state is defined as simply the possession of any diabetic symptoms or of the progression of such symptoms to the status of chief complaints.

\*Assistant in Medicine, Harvard Medical School; assistant in medicine, Beth Israel Hospital.

†This group 97 per cent of the patients were over forty years of age at time of diagnosis, as contrasted with 51 and 65 per cent in other groups.

‡In this study the term "onset" refers to the date of clinical diagnosis and institution of treatment.

To the biologist this has brought unparalleled opportunity for study of metabolic processes and for providing continuous temporal orientation of vital processes that never before could be achieved. To him it has also brought a means of study of chemical relations almost hopelessly snarled.

To the physician it has brought a means of following in detail the action of drugs and distribution of hormones, and has cast new light on problems of metabolism and structure. It has hinted, but only hinted, at new therapeutic methods. As yet there is little hope that we shall find among the radioactive isotopes a control of infection or a cure of cancer. We have found with radioactive phosphorus palliation of certain types of leukemia, palliation of polycythemia vera and some retardation of plasma-cell myeloma. We have found that radioactive isotopic iodine may be taken up by an occasional cancer of the thyroid gland and its metastases and that some of the isotopes in colloidal form may be taken up by the reticuloendothelial system and thus irradiate tumor cells. There are other isotopes that might be useful but for one reason or another—the inherent toxic quality of the element, its long half-life or the specific localization—are unsuitable for use.

The practicing physician needs at present to be concerned with the problem of the atomic bomb. As one of the best educated persons in his community, and the only one technically qualified to evaluate the biologic effects of an atomic explosion, it is his responsibility to orient the members of his community regarding the problems raised by the hazard of such an explosion—problems that are in part psychologic, in part medical and in part organizational.

The air burst of an atomic bomb has many points in common with that of the more usual types of high explosive bombs, but at much higher intensity. An explosion of either type of bomb produces local heat and an air-pressure wave. The explosion of an atomic bomb also causes liberation of radiant energy ranging the whole electromagnetic spectrum from infrared rays to very short gamma rays, as well as producing a flux of neutrons. In an air burst of an atomic bomb the bulk of the fission products are carried to the stratosphere by the rapidly rising superheated air and gases, and are there so widely disseminated as to exert no dangerous effect under ordinary conditions. Hence,

there was little or no residual radioactivity to be reckoned with in the Japanese cities.

In an underwater burst, on the other hand, heat and blast are minor factors, but the bulk of the fission products are trapped in the water and spray deluged over the area, a wide zone thus being contaminated with radioactive materials.

It was this type of contamination that made radioactive the ships at Bikini, some of which are too "hot" radiologically to be of any use even up to the present time. In addition, in an underwater burst there may be activity of fairly short half-life as a result of neutron-produced radioactivity. Outside the immediate zone of the explosion the extent of the radioactive contamination will hinge on the speed and direction of the wind prior to the final settling out of the droplets of the radioactive water.

In the United States, as a result of the fairly high level of education, the ready means of disseminating information and what might even be denominated a national tendency to sensationalism the atomic bomb has been endowed with almost supernatural attributes. It is highly probable that in any threat of use of atomic weapons we ourselves should be more vulnerable than anyone else.

It is in this regard that the doctor can be of particular help in enabling those with less information than he to attain the proper perspectives in this new and startling field. Because the doctor is peculiarly fitted to deal with emergency situations, it is natural that much of the planning for atomic defense will fall upon his shoulders. The details of these plans are yet to be worked out because facts are being constantly added to our store of pertinent knowledge. However, sufficient data are available to enable the broad framework of meeting such a disaster to be sketched out.

This is now being done by the Office of Civilian Defense Planning with the aid and co-operation of the Atomic Energy Commission. For the present, the medical profession can best serve by reviewing its knowledge of the effects of ionizing radiation and the therapy of injuries produced by it as well as placing atomic weapons in their proper perspective not as virtually a supernatural force but rather a means of mass destruction cheap and irresistible but nonetheless subject to definite limitations.

toms being overlooked, as follows: weight loss, 64 cases (70 per cent of the total), polydipsia, 40 (58 per cent), and polyuria, 39 (57 per cent).

Table 4 confirms statistically the validity of classifying the complications separately from the symptoms of diabetes. This is further substantiated by the variation of their incidence among the different types of onset (Table 3).

Decompensation of carbohydrate metabolism can be defined quantitatively§. Thus, the patients with the diabetic type of onset are in advanced and the others in partial metabolic failure. There is a definite correlation between insulin need and the degree of metabolic decompensation (Fig. 1).

§Partial or advanced decompensation of the diabetic state is defined as simply the possession of any diabetic symptoms or of the progression of such symptoms to the status of chief complaints.

\*Assistant in medicine, Harvard Medical School; assistant in medicine, Tufts College Medical School; head, Diabetic Clinic, Beth Israel Hospital.

†In this group 97 per cent of the patients were over forty years of age; ‡At the time of diagnosis, as contrasted with 51 and 65 per cent in other groups.

§In this study the term "onset" refers to the date of clinical diagnosis and ‡ institution of treatment.

Insulin need is further shown to be greater in youth (Fig 2), but advanced metabolic decompensation raises the insulin requirement to a maximum level regardless of age (Fig 2B). The lesser insulin requirements of the older patients may be partly explained by the greater proportion of only partially decompensated patients in that group.

TABLE 3 Differential Characteristics of Types of Onset

To summarize, the factors that are correlated with enhanced insulin requirement, in order of effect, are a positive history of untreated glyco-

FIGURE 5 *Relation between Prior Glycosuria and Severity (Insulin Requirement) in Advanced Metabolic Decompensation (Diabetic Group)*

suria, advanced metabolic decompensation, youth, and partial decompensation.

The patients with diabetic complications as their presenting complaint were oldest, had less prior glycosuria and required least insulin. Paradoxically, 53 per cent had no diabetic symptoms even though they had complications of the disease (Table 3).

Blood sugar tests had been performed in a few cases in the years prior to diagnosis, and were usually negative because they had been performed in the fasting state. However, 9 fasting blood sugar and 3 sugar tolerance tests had been positive five

greater eventual insulin requirement than those with negative determinations.

It is conceivable that, if treatment had been started earlier in the course of the glycosuric phase, less insulin would have been required. This may also apply to the prevention of metabolic decompensation, since all 56 of these patients had been seen prior to symptoms.

The patients with negative determinations seem to be heterogeneous. There is one group with a long course, little hyperglycemia and greater tendency to develop complications and a second group with a tendency to rapid development of decompensation once hyperglycemia had appeared (Table 8). In the first, only a glucose tolerance test would have sufficed for diagnosis, in the second, time for diagnosis by any test was probably short. Even though the patients without glycosuria were in the earlier, hyperglycemic phase of diabetes, lack of treatment carried the same poor prognosis (Table 8).

Dolger<sup>7</sup> has raised the somber question whether diabetic complications are inevitable regardless of control, since they eventually occurred in all patients with well controlled diabetes. If the arteriosclerotic complications are included under this heading, this is more than an academic question in an aging population. However, the degree of hyperglycemia in the insulin-treated patient with best controlled disease is probably greater than that in the worst of the untreated patients with complications described above. Yet this group, given time, developed one or more of the diabetic complications. It is highly possible that a patient with diabetes controlled so as to enable him to enjoy normoglycemia at all times will never develop complications, but the disease probably can be so well controlled only in patients detected and treated in the early stage.

Accordingly, from the point of view of preventing metabolic decompensation or of minimizing insulin requirements and diabetic complications, a vigorous attempt to find and arrest diabetes at this early stage is highly important. Although by the age of forty (the youngest of the present group) only 1 out of 6 potential diabetic patients have already been detected,<sup>8</sup> the foregoing analysis indicates that this is none too early to begin the search for the asymptomatic stage of the remainder.

This study shows that in early diabetes single negative urinalyses for sugar do not rule out the disease. More important, even a single slightly positive test obtained under routine conditions, even though apparently overshadowed by one or more previous, simultaneous or succeeding negative tests, should be taken to mean diabetes unless a glucose tolerance test proves otherwise. A fasting blood sugar test is totally inadequate for this purpose.

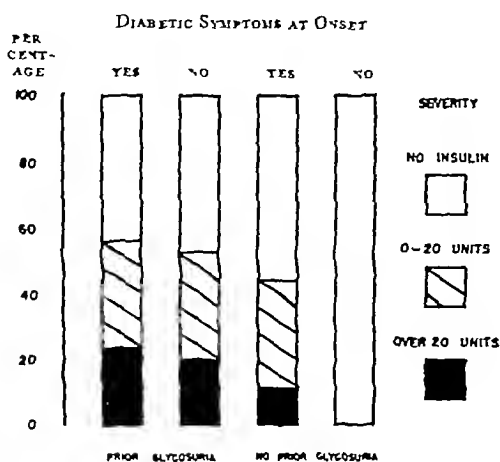

FIGURE 6 Relation between Prior Glycosuria and Partial Metabolic Decompensation (Complication and Casual Groups Combined) in Their Effect upon Severity (Insulin Requirement)

to fourteen years before final diagnosis and treatment.

### DISCUSSION

It is apparent that more exact classification of the symptoms of diabetes mellitus will help clarify concepts of this disease. Only 34 per cent of cases of advanced metabolic failure corresponded to the textbook description of the disease. A more complete history increased the incidence of symptoms to 77 per cent. However, almost a quarter of the cases remained to be discovered only by means of a glycosuria that was often only mild and intermittent.

True onset must be sharply separated from the clinical onset of diabetes. On the hypothesis of an earlier silent hyperglycemic in addition to a glycosuric stage of the disease (one to eleven years), prediagnosis diabetes would occupy a large portion of the adult life of a majority of diabetic patients. Both these periods may vary markedly in duration. In the purely hyperglycemic period, the individual patients, subjected to the stress of increasing hyperglycemia, react by developing metabolic decompensation or complications, or both. Those with more slowly developing decompensation have time to develop the complications. This explains the paradox of the appearance of a complication of this disease simultaneously with or even before symptoms.<sup>4-6</sup>

The patients with glycosuria showed both increase of their glycosuria through the years and

## SUMMARY

Only 34 per cent of a group of adult diabetics had classic diabetic symptoms as presenting complaints at the time of diagnosis. Diabetic symptoms of any type could be elicited from only 77 per cent of all the patients under consideration.

Diabetic complications were shown to be in a different category from the symptoms and were the presenting complaints of only 19 per cent.

There was a lower incidence of severe diabetic symptoms with increasing age.

Severity, as measured by insulin requirement, seemed to be correlated with the following factors: untreated prior glycosuria, metabolic decompensation and age (in order of decreasing importance).

Single, negative urinalyses are of practically no value for the exclusion of diabetes mellitus. Isolated asymptomatic glycosuria, regardless of a negative, fasting blood sugar test, should be considered diabetic unless a glucose tolerance test proves the contrary.

In 56 per cent of a group of adult patients, glycosuria had been noted up to sixteen years (80 per cent over two years) prior to definitive diagnosis. Glycosuria preceded symptoms by two to eleven years.

Detection and treatment in the earliest stage of the disease (hyperglycemic or glycosuric) is urged to prevent progression of severity or complications.

## FATAL TOXIC NEPHROSIS FOLLOWING THE ADMINISTRATION OF MERCURIAL DIURETICS\*

MICHAEL S. BRUNO, M.D.†

NEW YORK CITY

FATAL toxic nephrosis resulting from the administration of mercurial diuretics is undoubtedly a rare condition. When one considers the extent to which these drugs are used, as well as the failure to find lesions at autopsy that suggest that they have caused ill effects, it becomes evident that morbidity and mortality resulting from their use is infinitesimal.

Friedenson<sup>1</sup> has reported a case in which a total of 1250 cc of mercupurin (mercuzanthin) was administered over a period of several years to a young rheumatic patient. Autopsy failed to reveal demonstrable abnormalities in the kidneys after careful microscopical study. Gold et al.<sup>2</sup> observed the administration of mercurial diuretics in doses given two or three times weekly for periods of six months to three years and followed 3 patients who had received daily doses for periods of two to three years, without evidence of renal damage. Numerous other reports indicate that mercurials may be used frequently and over long periods without producing renal damage.

The first reported case of fatal toxic nephrosis following mercurial diuretics occurred after the administration of salyrgan.<sup>3</sup> Since then 2 additional

cases have been reported,<sup>4, 5</sup> but the diagnosis is not conclusive in either of these cases.

The history of mercurial diuretics since their introduction has been essentially a search for means of reducing their toxicity. Despite all efforts to render the organic mercurials innocuous, however, toxic reactions continue to occur.

### TYPES OF TOXIC REACTIONS

Toxic reactions following the administration of mercurial diuretics may be classified in five groups: local reactions, allergic reactions, sudden death, reactions due to the diuretic response, and mercurialism.

**Local reactions.** Burning, smarting, erythema, local histamine-like reactions and an occasional sterile abscess have occurred after intramuscular administration.

**Allergic reactions.** Allergic reactions varying from mild to severe episodes have been reported. Fox, Gold and Leon<sup>6</sup> described a case in which the patient reacted severely to the injection of both salyrgan and mercupurin. Apparently sensitivity to the drug is related to its molecular structure as a whole inasmuch as these reactions can frequently be avoided by employing another preparation. Changing the mode of administration, however, failed to alter both the occurrence and severity of reactions in patients who had previously demon-

\*From the Fourth (New York University) Medical Division, Bellevue Hospital.

†Assistant resident in pathology, Fourth (New York University) Division, Bellevue Hospital.

strated hypersensitivity. The occurrence of an allergic reaction should give the physician pause, lest further administration of the offending drug result in more severe reactions and even in death.<sup>7</sup>

**Sudden death.** This reaction has occurred only after administration by the intravenous route. In 1942 DeGraff and Nadler<sup>8</sup> collected 26 such cases. A number of cases have been reported since that time.<sup>9-10</sup> In some cases the initial dose was the fatal one, whereas in others, patients had received many previous injections without untoward reaction. Barker, Lindberg and Thomas<sup>11</sup> thought the deaths to be on a cardiac basis, and, after considerable animal experimentation, it was concluded that sudden death was the result of ventricular fibrillation. The opinion was expressed that mercurial diuretics acted primarily on the heart through the mechanism of vagal stimulation, and on the respiratory center if the vagal effect was removed.

Volini, Levitt and Martin<sup>10</sup> reported 3 cases of sudden death following an intravenous injection of a mercurial diuretic, and in 2 of these the electrocardiogram taken just prior to death demonstrated the presence of ventricular fibrillation.

**Reactions due to the diuretic response.** The diuretic property of mercurial compounds, first described by Saxl and Heilig<sup>12</sup> in 1920, has proved to be a most valuable tool in the treatment of cardiac failure. Mercurial diuretics are the most potent and effective diuretic drugs available to the physician. The urine excreted in response to the drug has a chloride ion concentration much greater than that usually present. Concomitantly, there is a decrease in the serum chloride concentration. This decline in serum chlorides is related to the fact that the kidney under the influence of a mercurial diuretic fails to reabsorb chloride ions in normal amounts, and thus the concentration in the urine is greater than that present in an equivalent volume of body fluid.<sup>13</sup> Occasionally, when there is a profuse diuresis, symptoms related to electrolyte depletion may appear. These symptoms of dehydration may occur despite the presence of peripheral edema. This is probably related to the removal of a large amount of edema fluid containing disproportionately greater concentrations of chloride ions, leaving behind extracellular fluid containing solutes in lower than normal concentration.

Another reaction that has been described is that of digitalis toxicity due to its mobilization from extracellular fluid by the mercurial diuretic. This reaction is probably not nearly so common as is thought, and concern over its occurrence may be obviated by the initiation of mercurial diuretic therapy with smaller doses in fully digitalized patients.

**Mercurialism.** Poisoning due to the mercury ion per se after the parenteral use of organic mercurial diuretics is rare. Mercurialism is seen most frequently after the administration of inorganic mer-

cury compounds, such as bichloride of mercury. The signs and symptoms of such toxicity are referable to the gastrointestinal tract and the kidney. In the kidney the effect of mercury is to produce a toxic nephrosis in which the damage is localized in the tubules. Although, as mentioned above, organic mercurial diuretics rarely cause mercurialism, probably because the mercury is in a nonionizable organic combination, when it does occur, the signs and symptoms are in no way different from those following the administration of inorganic mercury compounds. Kidney damage after the administration of organic mercurials is exceedingly uncommon, and damage sufficient to cause anuria, uremia and death is rare. For this reason the following case is reported.

### CASE REPORT

H. N., a 49-year-old woman, was admitted to Bellevue Hospital for the first time on September 15, 1947, with the chief complaints of generalized edema and severe dyspnea of 1 month's duration.

About 15 years previously, the patient was told that she had diabetes mellitus. The diabetes was well controlled for about 13 years by diet alone, but a symptomatic relapse 2 years before admission necessitated a daily injection of 35 units of protamine zinc insulin. The patient's diabetes remained well controlled thereafter. In December, 1946, the patient had begun to have exertional dyspnea, orthopnea, paroxysmal nocturnal dyspnea and ankle edema. The severity of these symptoms progressed rapidly, and she was referred to the cardiac clinic of another hospital. She was followed at weekly intervals for 3 months and was digitalized and maintained on 0.1 mg of digitoxin daily. In addition, she was placed on a low-salt and limited-fluid intake and given weekly injections of mercupurin intramuscularly. Despite all therapy the symptoms progressed and in April she was admitted to the other hospital.

Physical examination showed a blood pressure of 210/84 and evidence of hypertensive arteriosclerotic changes in both retinas and distention of the neck veins. The thyroid gland was enlarged to three times its normal size, and there were several hard nodules in the left lobe. A few crackling rales were heard at both bases, and there was evidence of free fluid in the lower half of the right side of the chest. A harsh systolic murmur was heard over the entire precordium and was loudest at the base and extended into the neck. There was also a high-pitched diminuendo diastolic murmur at the base, which was transmitted downward along the sternum to the apex. The liver edge was palpable 2 cm below the right costal margin. There was no ascites, but there was marked pitting edema of both legs and thighs and moderate sacral edema.

Examination of the urine revealed a +++ test for albumin. The fasting blood sugar was 165 mg, the total protein 6.0 gm (with an albumin-globulin ratio of 3:4:2:6), the cholesterol 278 mg, the calcium 9.4 mg, and the phosphorus 4.4 mg per 100 cc. Two phenolsulphonphthalein tests disclosed 70 and 65 per cent excretion of the dye in 30 minutes. Two urea clearance tests were reported as 35.0 and 35.7 per cent of average normal.

The patient was put on complete bed rest and a low salt and limited-fluid diet. She was continued on 0.1 mg of digitoxin daily without improvement. On the 14th hospital day, the patient was started on 2 cc of mercupurin intramuscularly and 6 gm of ammonium chloride daily. This regimen was discontinued after 3 days because the diuretic response was poor. The patient developed signs of increased fluid at both bases, and the daily dose of digitoxin was raised to 0.2 mg. In the next few days she began to lose weight. Thoracenteses on three separate occasions yielded 500, 550 and 400 cc of clear fluid. A daily dose of 6 gm of ammonium chloride and 2 cc of mercupurin intramuscularly every other day was reinstituted, with marked improvement. Between the 37th and the 39th hospital day, the blood urea

nitrogen rose to 60 mg per 100 cc, whereas it had previously ranged around 25 mg, and mercurhydrin was discontinued. The patient was discharged to the cardiac clinic asymptomatic, but at the time it was believed that she was entering a terminal phase of uremia.

The patient was seen at the clinic at weekly intervals and was given 2 cc. of mercurhydrin intramuscularly at each visit. Digtoxin, 0.1 mg daily, was continued in addition to a low-salt diet. Despite all therapy and a marked curtailment of activity, the original cardiac complaints returned within 2 months, and she was readmitted to the hospital. While there she had numerous thoracenteses, 2 cc. of mercurhydrin was administered intramuscularly three times a week, and 0.2 mg of digtoxin was given each day. She improved somewhat and was discharged to the clinic, where she was followed on the same regimen. In the next 4 weeks the patient developed severe dyspnea, orthopnea, paroxysmal nocturnal dyspnea and anasarca, and was referred for admission to Bellevue Hospital.

Physical examination revealed a poorly developed, well nourished woman in acute respiratory distress and with anasarca. The pertinent physical findings were evidence of hypertensive arteriosclerotic changes in both retinas, a markedly enlarged left lobe of the thyroid gland and distention of the neck veins. There were bubbling rales and rhonchi in both lungs and signs of fluid at the right base. The heart sounds were obscured by the respirations. The cardiac rhythm was regular. The abdomen was tense and distended, and a fluid wave was present. The liver and spleen were moderately enlarged. There was very marked edema of the lower extremities, with moderate edema of the remainder of the body.

The temperature was 98.6°F, the pulse 88 and the respirations 32. The blood pressure was 170/70.

Urinalysis revealed a +++ test for albumin, a trace of sugar, no acetone and a few hyaline and granular casts in the sediment. Examination of the blood disclosed a red-cell count of 4,090,000, with a hemoglobin of 13.4 gm, and a white-cell count of 9400, with 79 per cent neutrophils, 14 per cent lymphocytes, 6 per cent monocytes and 1 per cent basophils. The Mazzini serologic test for syphilis was negative.

It was evident that the patient's condition was grave. She was put on absolute bed rest and a low-salt diet but was given as much fluid as she desired. A daily maintenance dose of 0.2 mg of digtoxin was ordered. The patient was weighed and given 2 cc. of mercurhydrin intramuscularly and 6 gm of ammonium chloride. On the 2nd hospital day she weighed 165 pounds. A paracentesis was performed, and 3000 cc. of fluid was removed. This reduced the patient's weight to 155 pounds. Since she had had a good diuretic response the day before, another 2 cc. of mercurhydrin was administered intramuscularly. The nonprotein nitrogen was 50 mg, the chloride 401 mg, the cholesterol 172 mg, and the cholesterol esters 46 mg per 100 cc, and the carbon dioxide combining power was 29 vol per cent. On the 4th hospital day the patient weighed 152 pounds but was clinically unimproved. She developed nausea and vomiting, and the digtoxin was discontinued. On the 5th hospital day a slight icterus developed, nausea and vomiting persisted, and a bigeminal pulse was present. The nonprotein nitrogen was 60 mg, the creatinine 1.76 mg, and the total protein 7.2 gm per 100 cc, the albumin-globulin ratio was 3:1.4:1. The serum sodium was 306 mg per 100 cc, and the icteric index was 50.

X-ray films revealed engorgement of both lungs with thickened pleura and evidence of free fluid in the lower half of the right pleural space. On the 6th hospital day a third 2-cc. dose of mercurhydrin was given intramuscularly. The patient continued to excrete urine in large amounts and lost 4 pounds, the weight dropping to 153 pounds. However, the weakness progressed to the point where she could not get out of bed for her daily weighing, and it was decided that her urine output would be checked instead. On the 8th hospital day a thoracentesis was performed, and 740 cc of fluid was removed.

It was then decided that a more vigorous dehydration regimen was necessary as the clinical course was progressing rapidly downhill. Since mercurhydrin had produced excellent diuretic responses up to this point, it was decided to administer 2 cc. of mercurhydrin intramuscularly every 12 hours. Therapy was continued for 5 days. During this period the patient voided adequate amounts of urine but she became

incontinent and exact measurement of the output soon became impossible. On the 12th hospital day, mercurhydrin was discontinued since the nonprotein nitrogen had risen from 100 to 160 mg per 100 cc. in a period of 4 days. The carbon dioxide combining power dropped from 36 to 28 vol per cent. By the 14th hospital day, the patient became incontinent and disoriented. She lapsed into coma and died on the 16th hospital day.

Post-mortem examination 8 hours after death showed moderate icterus and anasarca. The trachea was shifted to the right, and a stony-hard, freely movable mass was palpable in the substance of the left lobe of the thyroid gland. The left pleural cavity was partially obliterated by dense fibrous adhesions, the right pleural cavity contained approximately 1000 cc of clear, yellow fluid. The abdominal cavity contained 4000 cc. of similar fluid.

The heart was moderately enlarged, weighing 500 gm. There was sclerosis of the leaflets of the mitral and aortic valves and some thickening and shortening of the mitral chordae tendineae. There was some hypertrophy of the left ventricle, moderate sclerosis with narrowing of the coronary arteries and focal myocardial fibrosis. The lungs were congested but were otherwise normal. The liver weighed 1320 gm, and its surface was covered by dense fibrous adhesions.

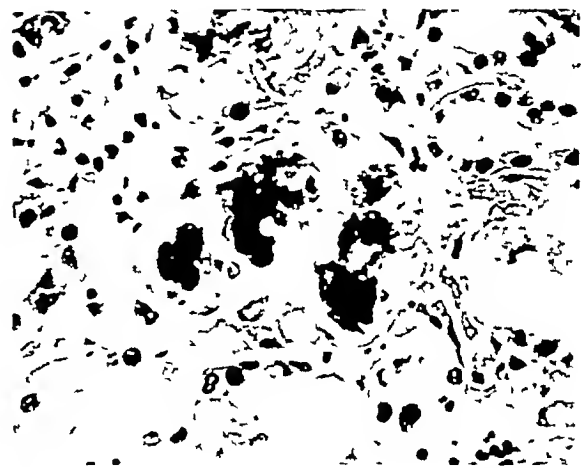

FIGURE 1 Photomicrograph of the Kidney, Showing Recent Calcium Deposition in the Necrotic Tubular Epithelium (X258)

About the efferent veins a narrow, red zone was seen. The spleen, pancreas, adrenal glands and biliary tree were normal.

The left kidney weighed 220 gm, and the right 210 gm. There was a deep U-shaped scar in the cortex of the lower pole of the right kidney. Both capsules stripped with ease, revealing a surface that was finely granular. The parenchyma was moderately congested, the cortex was thin, the pyramids were of average size and color and the corticomedullary junction was well demarcated. The pelvic organs and gastrointestinal tract were not unusual.

The thyroid gland weighed 160 gm. The left lobe was almost completely replaced by a single nodule, which was calcified and well encapsulated. The remainder of the gross anatomic findings were not remarkable.

Histologic examination showed that in the kidney many of the glomeruli had been transformed into compact masses of hyalin. In other glomeruli small rounded masses of hyalin were found at the periphery of the tuft. The basement membrane of the capsule of Bowman was frequently thickened and the space of Bowman filled with a granular precipitate. Epithelial cells of the proximal convoluted tubules were occasionally seen that were swollen, the cytoplasm being dense and the nucleus pyknotic. Some of these necrotic cells were still in their normal position, others were free in the lumens. Masses of calcium were found in the lumens of these tubules.

in others calcium clumps were present in tubules so altered that it was impossible to identify them. In places the calcium clearly lay in necrotic desquamated epithelial cells and appeared to have been recently deposited (Fig 1). More frequently the calcium deposits appeared to have been present for a longer time (Fig 2). Tubules that were lined with flattened cells having a large elongated nucleus and much chromatin were often seen. Occasional mitotic figures were

FIGURE 2 Photomicrograph, Showing Old and Recent Calcification of a Number of Kidney Tubules (X72)

noted in the epithelial cells. The interstitial tissue was moderately increased. Calcium was found to be deposited in the media of a large artery near the tip of a pyramid, and the intima of the vessel was markedly sclerotic.

The Reinsch test for mercury was performed on 10 gm of kidney tissue, and mercury was found to be present in large quantities. It was estimated that approximately 0.3 to 0.5 mg of mercury was contained in the 10 gm of kidney tissue examined.

The anatomic diagnosis of toxic nephrosis due to mercury, with extensive calcification of the kidney tubules, intercapillary glomerulosclerosis and Mönckeberg's sclerosis, was made. Other incidental lesions were those of tuberculous endometritis, biliary cirrhosis, chronic passive congestion of the spleen and lung, focal accumulation of fat in the myocardium, adenoma of the thyroid gland with calcification and hyperplasia of the parathyroid gland.

### DISCUSSION

Why fatal toxic nephrosis following the administration of mercurial diuretics should occur remains a puzzling problem. The fact that many patients receive these drugs in large doses for prolonged periods without clinical or autopsy evidence of renal damage indicates that there were unknown factors in the case presented above. Whether pre-existing kidney damage contributes to a toxic nephrosis is a much debated point, although much evidence is accumulating that patients with renal impairment respond satisfactorily to the administration of mercurial diuretics.<sup>14</sup> Indeed, as Goldring<sup>15</sup> has indicated, there is no reason for believing that a diseased kidney is more vulnerable than a normal kidney to the nephrotoxic action of mercury. "In fact, it might be supposed that the functionally im-

paired kidney is less likely to injury, since its inability to concentrate would result in a more dilute solution of mercury in its tubular fluid than in the normal kidney."

What part the large dosage of mercury played in the outcome in this case is also questionable, since such large doses have been given to other patients with renal impairment without ill effect. Although some of the calcification seen in the kidney sections appears to have been of recent origin, much of it seems to have been present for a longer time. This indicates that considerable calcification occurred while the patient was being given smaller doses of the drug as well as when she was on the larger, more recent dosage.

The mercurial diuretics are indispensable in the treatment of many cardiac conditions. The dramatic conversion of a bedridden patient in congestive heart failure to a useful social and economic position in society would often be impossible without these drugs.

In a recent study<sup>16</sup> their importance was emphasized by comparison with digitalis in the control of heart failure, and it was suggested that "in patients with chronic advanced failure who require mercurial diuretics, the mercurial is often the drug of greater importance but that in such cases with auricular fibrillation, digitalis may continue to serve a useful purpose which is not as apparent in those with a normal rhythm." Gold et al<sup>2</sup> believe "that the sequence employed in the most common practice of trying digitalis first and then adding a diuretic, if necessary, is in need of revision." The basis of their system of therapy rests upon an effective technic for dehydration, with salt restriction, free supply of water and the use of a potent diuretic. The excellent results obtained by this group in the treatment of congestive heart failure, in comparison with routine methods employed by others, testifies to the increasing importance of the mercurial diuretics.

It would be extremely unwise to discard or in any way to limit the therapeutic application of mercurial diuretics because of an occasional toxic reaction. Deaths following the administration of these drugs are extremely rare, and sudden death has occurred only after intravenous administration. There probably exist no contraindications to the use of the drugs other than severe allergic reactions and oliguria or anuria, as in acute glomerulonephritis, lower-nephron nephrosis and other conditions.

Dilution of an individual dose or slowing of the injection time has not reduced the incidence of toxic symptoms.<sup>17, 18</sup> Previous medication with other drugs, such as digitoxin, aminophylline, ammonium chloride and the barbiturates, has not lowered the animal lethal dose.<sup>8</sup>

Probably the surest way to avoid severe toxic reactions would be to avoid administering mercurial diuretics intravenously, except in the few cases of severe congestive failure with acute pulmonary edema in which time is of the greatest importance, to administer a small test dose when the drug is given for the first time, and to change the mercurial diuretic to another drug of this group when an allergic reaction has occurred

### SUMMARY

A case of fatal toxic nephrosis following the administration of multiple intramuscular doses of a mercurial diuretic is reported. Other toxic reactions are discussed.

### PHYSICAL RISKS OF ELECTROCONVULSIVE THERAPY

RUDOLPH KALDECK, M.D.,\* WILLIAM F. McLAUGHLIN, M.D.,† JOSÉ GURRI, M.D.,‡ AND JOSEPH I. WASSERSUG, M.D.§

BOSTON

ELECTROSHOCK therapy is the most widely used of the somatic methods for the treatment of mental diseases. It is not the purpose of this investigation to describe the therapeutic result achieved or to compare its relative value with other procedures, both somatic and psychotherapeutic. We wish only to evaluate the physical risks involved in this form of treatment. Many papers have been written in the past few years about the subject. Kalinsky and Hoch,<sup>1</sup> in their excellent textbook, summed up their own experiences and reviewed the literature up to 1945. We hope the close cooperation of our medical and psychiatric staff has made it possible for us to add a few findings of practical value.

This report is based on the observation of 628 patients who received 8082 electroshock treatments at the Boston State Hospital during the six-year period from 1942 through 1947. The only fatal case associated with electroshock therapy occurred early in this period.

A twenty-three-year-old man, who had been suffering from paranoid schizophrenia for more than four years, died on March 14, 1942, eighteen hours after the eighth treatment in a second series of electroshock therapy. Autopsy by the state pathologist, Dr. Jetter,<sup>2</sup> who reported the case in detail, revealed an acute glomerulonephritis, which was considered to be of several days' duration, acute focal myocarditis and acute pulmonary edema. Physical and laboratory examination prior to the beginning of the treatment was negative.

Because of this unfortunate experience, we became extremely conservative in the selection of patients. Practically every kind of organic disease and physical defect was considered a contraindication to this form of therapy. However, with increasing experience, it became obvious that such an overcautious attitude deprived too many patients in need of the treatment of its benefit. An increasing number of patients with abnormal findings and advanced age were accordingly treated, without ill effect, although this does not mean that electroshock therapy can be used indiscriminately.

A thorough physical examination of every patient preceded the electroconvulsive therapy. It consisted, in addition to a routine clinical exam-

ination, of a 7-foot x-ray film of the chest, urinalysis, complete blood count, a serologic blood test and a determination of the blood sugar and non-protein nitrogen. The temperature, pulse, respiratory rate and blood pressure were taken prior to each treatment. Additional tests, such as sputum examinations, sedimentation rate and electrocardiograms, were done when thought necessary. Whenever these examinations justified any doubt, the patient was seen by medical consultants to whom we are very grateful for their help and understanding in weighing the risk of the treatment against the expected therapeutic effect. Definite contraindications were found to be rare.

### AGE

It is now generally accepted that old age in itself is not a contraindication to the use of electroshock therapy. Feldman et al.<sup>2</sup> treated 53 patients over sixty-five years of age, none of whom showed any clinical evidence of injurious effects from the treatment. Thirty-one of our patients were over sixty years old, 4 being sixty-nine and 1 seventy-two. It might be added that during the current year we have already treated 4 patients over seventy. One had diabetes, and several had generalized arteriosclerosis and enlargement of the heart as shown by x-ray study. Marked hypertension was present in 5 elderly patients, the blood pressure was 185 systolic, 110 diastolic, in one, and 172 systolic, 114 diastolic in another. Some had clinical and electrocardiographic evidence of coronary-artery disease. A sixty-nine-year-old woman had had a coronary thrombosis four years previously while a patient in a private mental hospital. Although she was severely depressed and agitated, electroconvulsive therapy was considered too hazardous at the time. Later, transferred to this hospital, she was mentally unimproved, and electrocardiographic examination confirmed the diagnosis of coronary infarction. Her mental condition was markedly improved after thirteen electroshock treatments. This woman and the other elderly patients withstood the treatment well and developed no complications.

As children have not been admitted to this hospital during the past few years, we can report only 1 case—that of an eleven-year-old girl, who was in an extremely stuporous condition and had had to be fed by tube daily for several months. Six weeks prior to admission, a ventriculogram had been performed in another hospital to exclude organic brain disease. As her mental condition did not improve, she was given seven electroshock treatments, with excellent results. She acted and talked like a normal child and was soon back in school.

### UNDERNUTRITION

Undernutrition is a frequent finding among mental patients on account of overactivity and refusal to eat. In the preparation of these patients for shock treatment it is often impossible to improve their nutritional condition. However, it is very important not to treat them in a state of dehydration. This can be averted by tube feedings and parenteral administration of fluids if the patient cannot be induced after the intravenous use of sodium amytal to take nourishment. However, too much time should not be taken in preparing the patients, since it is a common and gratifying experience to find them eating ravenously after one or two treatments. The nutritional condition improves so rapidly in these cases that the treatment can be considered a life-saving procedure. One patient, a twenty-five-year-old woman with catatonic excitement, showed extreme emaciation, amenorrhea, loss of hair, hypotension, subnormal temperature and hyperpigmentation so that an endocrinologic disturbance, such as Addison's or Simmonds's disease, was seriously considered. After seven electroconvulsive treatments, she was in full remission, her physical condition improved rapidly and she was able to leave the hospital.

Another patient, a thirty-one-year-old man who was 6 feet tall, and whose weight was down to 83 pounds, in a catatonic stupor, refused to eat and was fed by tube daily for two months. Permission for shock treatment was received from his family only after his weight had decreased so severely that his condition had become critical. After the second electroshock treatment, he began to eat by himself, and his physical condition improved rapidly. Six weeks after a series of fifteen electroconvulsive treatments, his weight was 125 pounds, he too was able to leave the hospital on a visit. In these 2 cases, the shock therapy was life saving. They indicate that severe malnutrition is no contraindication to convulsive treatment.

Secondary anemia, which is often associated with malnutrition, was found in several patients. Even when the red-cell count was less than 3,000,000, the treatment was not excluded. With better food intake after the electroshock therapy, the condition of the blood also improved. When necessary, the patients received iron and liver medication, but electroconvulsive therapy was not delayed by the medical treatment.

### CARDIOVASCULAR DISEASES

Cardiovascular diseases present the most common cause for withholding electroconvulsive treatment from patients in need of it. However, as early as 1942, Myerson<sup>1</sup> pointed out that the damage to the heart from the psychosis itself put a greater burden on the cardiovascular system than the shock treatment. Among our patients

were 27 in whom enlargement of the transverse diameter of the heart was noted on 7-foot x-ray films. Ten of these patients showed clinical and roentgenologic evidence of arteriosclerotic heart disease, often accompanied by generalized arteriosclerosis. One patient, a sixty-two-year-old woman, with a diagnosis of psychosis with cerebral arteriosclerosis, received twelve electroshock treatments with no untoward physical effects. However, she remained agitated and depressed, and lobotomy was later performed. At operation, the neurosurgeon found advanced arteriosclerosis of the cerebral vessels, with severe atrophy of the brain. After lobotomy, her mental condition showed marked improvement. This is a proved case of advanced cerebral arteriosclerosis in a patient who withstood a course of electroshock treatment without physical damage.

Twenty patients had abnormal electrocardiographic findings, varying from simple left-axis deviation, low voltage and an inverted T wave in Lead 4 to signs of definite coronary-artery disease. The case of a woman with coronary thrombosis was described above among the group of elderly patients. Another patient, who was known to have congenital heart disease (patent ductus arteriosus), received nineteen electroshock treatments. Still another patient, a thirty-seven-year-old woman with a severe agitated depression, had rheumatic heart disease with mitral stenosis and aortic insufficiency. She had a history of several episodes of severe decompensation. After five electroshock treatments, she became decompensated again and had to be digitalized. Her mental condition was markedly improved. All the other heart cases showed no untoward physical effects whatsoever.

Marked hypertension was found in 16 patients, 4 of them with a systolic pressure of more than 200. One woman of fifty-eight with an enlargement of the heart on x-ray study had a blood pressure of 220 systolic, 140 diastolic. Her severe, agitated depression, which did not respond to any kind of sedation, made electroshock necessary in spite of the risk. She had seventeen treatments, and like the rest of the patients with hypertension, did not show any ill effect. In many cases the blood pressure dropped to normal levels when, as a result of the treatment, agitation and tension subsided. Seven patients, who showed very little or no mental improvement, had marked hypertension at the end of the treatment although the blood pressure had been normal at the onset. In 1 patient, a forty-five-year-old woman, the blood pressure, which had been 138 systolic, 92 diastolic, before treatment, rose to 174 systolic, 110 diastolic, after nine electroshock treatments. In a few other patients it went up and down in a way that could not be easily understood, since it was, sometimes, incon-

sistent with the emotional state of the patient. One observation especially appeared to be remarkable. A woman in her middle fifties, in a severe depression very close to complete stupor, had a blood pressure of 158 systolic, 108 diastolic, at the beginning of treatment. After only four treatments she was in full remission, but her blood pressure rose to 220 systolic, 118 diastolic. The patient left the hospital four weeks after the treatment and remained well, both physically and mentally, during a follow-up period of more than a year. Obviously the blood pressure became high when she came out of her stupor, hypertension was normal for her cardiovascular system as soon as compensation was established.

Among 4 patients with hypotension a forty-nine-year-old woman, who had had a blood pressure of 90 systolic, 70 diastolic, showed prolonged cyanosis after the first electroshock treatment. With improvement of her mental condition her blood pressure and pulse pressure went up, and further treatment went on without any incident.

Five or six patients in whom cyanosis and poor quality of pulse persisted for more than a few minutes after treatment had not shown any physical abnormal findings prior to the treatments. They recovered instantaneously after application of oxygen and stimulants.

None of these patients with cardiac findings, hypertension, hypotension or unusual oscillations of blood pressure showed any ill effects from the treatment.

#### PULMONARY TUBERCULOSIS

The high incidence of pulmonary tuberculosis among patients in mental institutions is well known. The question frequently arises whether or not electroshock therapy should be given. Several cases have been reported in the literature with spread or reactivation of the tuberculous lesions after electroconvulsive therapy. The increased intrathoracic pressure, the pulmonary congestion and the anoxia may all have deleterious effects. However, it should be kept in mind that soft and active lesions are prone to spread anyway. There are no investigations available that would demonstrate whether such activations occur more frequently with or without electroshock therapy. Norman and Shea<sup>5</sup> reported from the Foxborough State Hospital the cases of 2 patients who developed active pulmonary tuberculosis after electroconvulsive therapy. Will and Duval<sup>6</sup> described another case from St. Elizabeth's Hospital in Washington, D. C., and reviewed the whole literature up to 1947.

In our own cases we tried to evaluate the criteria of activity or inactivity as much as possible before giving electroconvulsive therapy. It is obvious that x-ray findings are not the sole basis for the

diagnosis Whenever the roentgenologic impression indicated a tuberculous process, the patient was seen in consultation by a tuberculosis consultant, and further laboratory examinations such as examination of the sputum or stomach washings for tubercle bacilli and sedimentation rates were performed

Twenty-five patients had healed pulmonary tuberculosis, the findings in 15 additional cases were considered doubtful All these patients received routine courses of electroshock therapy without activation of the pulmonary process

Eight additional patients were considered to have active pulmonary tuberculosis, and 2 probably active The diagnosis was based on x-ray findings, sedimentation rate and evaluation by the tuberculosis consultant, although acid-fast bacilli could not be found One of these patients, with a manic-depressive psychosis, had an exudative pleurisy of the left side prior to shock treatment After a series of fifteen electroconvulsive treatments, her great overactivity subsided, but she developed a pleuritic exudate on the other side A tuberculous pleurisy often spreads to the other side, and it is difficult to say how much the shock treatment had to do with it The other 7 patients in whom the examination prior to electroconvulsive therapy revealed a tuberculosis of some activity showed mental improvement or at least less agitation after shock treatment This may be the reason why their mild tuberculosis is taking a favorable turn

Another case presented an extraordinarily grave problem an active pulmonary tuberculosis, of serious prognosis in itself, occurred in a patient who was in a state of severe catatonic excitement It was obvious that active therapy had to be started immediately As any therapist in this field may face such a case some day, and will have to make his decision, this case is presented in greater detail

A 20-year-old Negress was admitted in an active schizophrenic attack, which had started a few days before Her catatonic excitement became gradually worse sedation and continuous baths were applied with little success She refused to eat and had to be fed by tube She lost weight and had subfebrile temperatures A chest plate revealed soft areas of infiltration in the right apex and the first right intercostal space The blood sedimentation rate was increased

On July 18, 1947, a right pneumothorax was performed by one of us (J D W) The filling was increased 2 days later and resulted in good collapse of the lung On July 21, she received the first electroconvulsive treatment Subsequently, every other day she had a shock treatment or a fluoroscopic checking of the lungs with refilling of the pneumothorax, when necessary Her condition improved steadily After the first shock treatment she was eating, and the intervals between single treatments could be made longer Altogether she had nineteen electroshock treatments, the last on September 3 One month later, she was released from the hospital, mentally in full remission and with the right lung in good collapse At present she is attending one of the tuberculosis units in this city for maintenance of her pneumothorax and is working as an office clerk

Two patients had had normal chest films prior to electroconvulsive therapy Both had been in mental hospitals for years One, a twenty-eight-year-old woman, with chronic catatonia, had five electroshock treatments without improvement Six months after convulsive therapy, she developed a rapidly progressive pulmonary tuberculosis from which she died three months later The other patient, a sixty-three-year-old woman with agitated depression and confusion, had signs of cerebral arteriosclerosis On account of her severe agitation she received eighteen electroconvulsive treatments within a period of ten weeks without improvement A few weeks after discontinuation of shock therapy, she developed a high temperature, additional chest films showed a bilateral active tuberculosis The pulmonary infection took a rapid course, and she died four months later After the development of the tuberculosis, the chest plates that had been taken of both patients prior to shock treatment were scrutinized again and even then the films had to be considered normal As a certain number of patients with chronic schizophrenia may be expected to develop pulmonary tuberculosis, it remains an open question if and how far the shock treatment should be considered responsible for the activation of the process In any case, as the chest films prior to electroconvulsive therapy were entirely normal, we had no reason to withhold the treatment in these cases

In summary our experiences with the problem of electroconvulsive therapy of mental patients who are simultaneously suffering from pulmonary tuberculosis indicate that the treatment carries definite risks On the other hand, if the patient becomes exhausted by overactivity or refuses to eat, the prognosis of the pulmonary process is in itself very serious In each case it is necessary to evaluate carefully the degree of the tuberculous lesions, their possible aggravation by the psychosis and the result expected from the shock treatment There is a good argument for the use of electroconvulsive therapy in selected cases of pulmonary tuberculosis even if some degree of activity is present If the activity is high or if there is a history of recent hemorrhage, shock should be given only when the pulmonary process has been controlled by some collapse measure, such as pneumothorax There are cases in which collapse therapy and electroshock have to be applied simultaneously

#### BRONCHIECTASIS

Six patients had roentgenologic signs of bronchiectasis without increased secretion They had no ill effects from electroshock therapy

#### ACUTE INFECTIONS

All patients suffering from acute infections should be excluded from electroshock therapy

Whenever any upper respiratory infection was present, treatment was postponed. The same rule was followed in local infections as abscesses or cellulitis. A few patients with chronic otorrhea were given electroshock therapy without ill effects. These cases were evaluated first by clinical examination, x-ray study of the petrous bones, blood sedimentation rate and white-cell count. When any activity of the ear infection was found, the patients were not treated. If there could be any doubt about the rule that patients with acute infections should not be given electroshock treatment, this was re-emphasized by the only fatal case connected with electroshock that occurred in this hospital. As mentioned above, post-mortem examination in that case revealed an acute glomerulonephritis of several days' duration. One of the 2 fatal cases after electroshock treatment recently reported by Riese,<sup>7</sup> was very similar to that discussed above. A thirty-year-old obese woman died forty-eight hours after electroshock treatment. Post-mortem examination showed subacute cystitis and acute pyelonephritis. If any conclusions can be drawn from cases of this kind, they are that intercurrent infections must be watched for during a course of electroshock treatment as well as prior to it. A urine examination should be made at least once a week during a course of treatment.

#### BONE DISEASE, FRACTURES AND DISLOCATIONS

Any kind of bone lesion found prior to electroshock treatment is important, since a higher incidence of fractures can be expected in such cases. A few observations confirmed this opinion. One patient, whose x-ray examination had shown narrowing of the interspaces between the dorsal vertebrae, sustained a fracture of the third dorsal spinous process from electroshock therapy. Another patient, a thirty-eight-year-old woman, had an ankylosis of the right elbow from an old fracture. During the sixth electroshock treatment, she suffered a fracture of the neck of the right humerus, most probably because too much pressure was exerted on the ankylotic limb during shock.

Observations of this kind should not lead to the exclusion of the needed treatment but should indicate that extreme care is necessary in placing such patients on the table and in exerting the proper amount of force in restraining them. As a matter of fact, in our series, numerous patients with bone disease were given electroshock treatment without damage. (A case of spina bifida is described below in the section on central-nervous-system disorders.) One patient had a severe kyphoscoliosis, and shock treatment had been considered in another hospital as too dangerous. As her catatonic excitement persisted, she received a series of electroshock treatments without ill effects. Five patients had scoliosis of moderate

degree, 2 had marked arthritic changes of the spine on x-ray study. One woman, thirty years of age, had multiple areas of increased calcification in the frontal region, which was considered roentgenologic evidence of enostosis frontalis. She received fifteen electroshock treatments without untoward result. Six patients had x-ray findings and histories of fractures prior to the treatment: an elderly woman had sustained a fracture of the jaw in an automobile accident only two and a half months before she had electroshock treatment, another patient, a sixty-five-year-old woman, had had a fracture of the right hip one year previously, 3 patients had old rib fractures, and 1 patient had an old occipitoparietal fracture of the skull, with slight bone depression and negative neurologic findings. All these patients had no ill effects from the treatment.

Fractures due to electroshock treatment occurred in 11 patients, including the 2 cases with previous bone disease mentioned above. Of the 9 patients without previous bone disease, 8 sustained fractures of the spine. As other observers have noted, all these fractures healed with amazingly little discomfort to the patient and without orthopedic treatment. One patient, a young man of nineteen in poor nutritional condition, suffered a fracture of the left acetabulum. Unlike the course in the case reported by Myerson,<sup>4</sup> the head of the femur did not penetrate into the pelvis, and there was no marked displacement of the fragments.

One dislocation of a shoulder occurred in a patient who later gave the information that he had had such an injury before. The humerus was replaced immediately without difficulty. In 3 cases dislocation of the jaw was easily reduced.

When the measures necessary to prevent injuries to the skeletal system are considered, the need of proper placing on the table, with one pillow under the small of the back and another under the knees of the patient, should be stressed. Only moderate restraint should be exerted by the assistants who hold the patient. Another measure, often recommended, is the preliminary administration of curare. As the drug has been tried by us in only a few cases, our experience is not sufficient to justify an opinion about this. However, the observations of other workers seem to show that the dangers of this drug outweigh its advantages. During a twelve-month period, ending June 30, 1946, 3 deaths occurred incident to the administration of electroshock treatment in all mental institutions of Massachusetts, 2 of these were associated with preliminary curare medication.<sup>8</sup> Several other fatal cases after the use of curare are reported in the literature. Of the 2 fatal cases recently described by Riese,<sup>7</sup> 1 was mentioned above in connection with acute infections. The other death occurred in a patient who had received curare prior to electroshock therapy. These and similar reports

explain our reluctance to use curare in the preparation for convulsive treatment

### CENTRAL-NERVOUS-SYSTEM DISEASES

A seventy-four-year-old man with seropositive syphilis and a severe depression had a positive cerebrospinal-fluid Wassermann reaction. Another patient, a woman of forty, had residual poliomyelitis. Both had no ill effects from the shock treatments.

Another patient, a thirty-one-year-old woman with a schizoaffective psychosis, who had not shown any abnormal physical findings prior to shock therapy, developed a transient hemiplegia of three days' duration after treatment. The paralysis disappeared without lasting damage to the patient. As there is still insufficient knowledge of the basic changes in the central nervous system caused by electroshock therapy, such a case might be of value toward a better general understanding of the pathology of electrically induced convulsions. In a separate report an attempt was made to explain this transient hemiplegia on the basis of vascular spasm, causing reversible structural damage in the motor pathways of one side of the brain.<sup>9</sup>

Another patient presented a considerable problem in the decision whether to give her electroshock therapy. She was a woman of thirty, who had a sacral spina bifida with a dorsally protruding meningocele the size of a large hen's egg. Extensive involvement of the spinal cord had caused a spastic paraparesis. Her right leg and several toes of her left foot had been amputated. She had dementia praecox with depressive and paranoid features, and was almost continuously disturbed. She was noisy and threw dishes and similar objects at nurses and doctors. Numerous consultations were had for two years, since we hesitated about giving her shock therapy. Finally, when her mental condition became worse and tube feeding had to be given frequently, a course of electroconvulsive treatment was started. Up to this writing the patient has received twenty treatments with no physical ill effects and marked mental improvement. Although some paranoid trends are still present she is well behaved and laughs and talks with everybody who comes to see her.

### MENSTRUATION AND PREGNANCY

Normal menstruation is no contraindication to the treatment. Only when the hemorrhage was profuse did we wait until it diminished. In the literature are several reports of pregnant women who received electroshock treatment without damage to mother or child.<sup>1</sup> We had no pregnant women in our series.

### DIABETES MELLITUS

Five patients had diabetes mellitus, 1, a woman of sixty with a manic psychosis, had blood sugar values up to 275 mg per 100 cc. She had an excellent remission after nine shock treatments. She, as well as the other diabetic patients, withstood electroshock therapy without untoward physical effects.

### SUMMARY

The physical risks of electroconvulsive therapy are discussed on the basis of a material of 8082 treatments received by 628 patients. Thirty-one of them were over sixty, and 5 over seventy years of age. All these patients responded well to the treatment, as did a child of eleven. Even severe undernutrition is no contraindication to the treatment.

About 50 patients had signs of cardiovascular diseases, such as arteriosclerosis, enlargement of the heart, abnormal electrocardiographic findings, rheumatic heart disease and hypertension. One had definite signs of coronary-artery disease, and another a severe congenital abnormality of the heart. In many patients, the increased blood pressure went down when agitation subsided as a result of electroshock therapy. In a few other cases, the blood pressure went up or up and down in a way that was not always consistent with the patient's emotional state.

Eight patients with active and 25 with arrested pulmonary tuberculosis were treated in this series. Shock therapy of mental patients who are suffering from tuberculosis carries definite risks, but in selected cases, electroshock therapy has to be given even if the tuberculosis is active. If there is a history of recent hemorrhage or if the activity is high, shock should be given only when the pulmonary process has been controlled by collapse therapy. In 1 case electroshock therapy and pneumothorax were applied simultaneously.

Patients suffering from acute infections should be excluded from electroshock treatment, and every effort should be made to discover intercurrent infections prior to and during a course of electroshock. This was emphasized by the one fatal case after electroshock therapy that occurred in this series.

Eleven cases of fractures due to electroshock treatment were observed, 2 of them occurred in patients who had bone disease prior to the treatment. All fractures healed without permanent damage. Regarding the preliminary administration of curare, the opinion is expressed that the danger of this drug outweighs its advantage.

A few patients with diseases of the central nervous system were treated without ill effects. Another patient, who had no abnormal physical findings prior to electroshock treatment, developed a

transient hemiplegia following the treatment, most likely on the basis of vascular spasm, causing reversible structural damage to parts of the brain

## MEDICAL PROGRESS

### X-RAY DIAGNOSIS OF PULMONARY LESIONS

LAURENCE L. ROBBINS, M.D.\*

BOSTON

THE roentgenologic examination of the chest readily reveals abnormality, but the determination of the exact nature of the process is more difficult. One way of approaching the diagnosis is dependent upon a knowledge of gross anatomy, pathology, physiology and x-ray shadows, in addition to having available the brief facts concerning the clinical status of the patient. The material collected for this review is presented on this basis.

From the anatomic standpoint, the recent studies of Boyden and his associates<sup>1-3</sup> of the bronchial and vascular structures of the lung, particularly the relation of the various segments, have been of value. Roentgenologically, Robbins et al.<sup>4-10</sup> have demonstrated the segments as they appear in collapse and the configuration of certain anatomic structures, such as the vascular network and hilar shadows and the interlobar septums or fissures, these have been found to be of importance in diagnosis. Medlar,<sup>11</sup> in a study of 1200 pairs of lungs, found that on the left side the major fissure was complete in 82 per cent, whereas on the right it was complete in approximately 70 per cent, and the minor fissure was complete in 38 per cent, in the other cases, the fissure was partially present (Whether the fissure is complete or not is of relatively little importance in determining its position roentgenologically in the majority of patients).

The azygos septum is important only in that it should not be confused with an abnormal process. Its incidence, as pointed out by Etter,<sup>12</sup> is 1.384 chests examined, Pendler<sup>13</sup> found it to be 1.6 per cent of 25,000 fluororontgenograms.

Lachman<sup>14</sup> reviewed present-day teaching of anatomy from a critical standpoint, stressing the

fact that the dynamic aspects as disclosed by x-ray examination differ considerably from the anatomy of the cadaver. Anatomy is not a fixed study, but one in which there is a good deal of motion of most of the thoracic structures. The posterior reflections of the pleura, sometimes spoken of as the pleuropleural demarcation lines,<sup>15</sup> are of diagnostic importance, loss of visibility of these lines in the roentgenogram may signify enlargement of the heart, pulmonary disease or fluid in the pleural space.

Westermarck<sup>16</sup> has utilized changes in intra-alveolar pressure in diagnosis of pulmonary as well as mitral lesions. He has been able to show that the degree of filling of the pulmonary vessels and of the chambers of the heart is profoundly affected by intra-alveolar pressures. A water manometer with a tube held in the patient's mouth is used so that pressures of water from -15 up to +80 cm are obtained. This method can also supply a rough measurement of the pressure in the pulmonary arteries by determining at which level vessels in the hilus diminish in size.

### TECHNIC OF EXAMINATION

From the technical point of view, there is still a tendency for utilization of the black and white films showing marked contrast. This technic is rather attractive, but unless additional procedures, such as the Bucky or grid films or more complicated methods are used the information that might be obtained by means of the roentgen-ray examination is considerably curtailed. For those who desire as many data as possible from conventional films, the optimum kilovoltage technic, as suggested by Fuchs,<sup>17</sup> will yield a far greater return. This technic produces a film that is rather gray, but all portions of the chest are adequately penetrated so that more

\*Associate in radiology, Harvard Medical School; radiologist-in-chief, Massachusetts General Hospital.

explain our reluctance to use curare in the preparation for convulsive treatment

### CENTRAL-NERVOUS-SYSTEM DISEASES

A seventy-four-year-old man with seropositive syphilis and a severe depression had a positive cerebrospinal-fluid Wassermann reaction. Another patient, a woman of forty, had residual poliomyelitis. Both had no ill effects from the shock treatments.

Another patient, a thirty-one-year-old woman with a schizoaffective psychosis, who had not shown any abnormal physical findings prior to shock therapy, developed a transient hemiplegia of three days' duration after treatment. The paralysis disappeared without lasting damage to the patient. As there is still insufficient knowledge of the basic changes in the central nervous system caused by electroshock therapy, such a case might be of value toward a better general understanding of the pathology of electrically induced convulsions. In a separate report an attempt was made to explain this transient hemiplegia on the basis of vascular spasm, causing reversible structural damage in the motor pathways of one side of the brain.<sup>9</sup>

Another patient presented a considerable problem in the decision whether to give her electroshock therapy. She was a woman of thirty, who had a sacral spina bifida with a dorsally protruding meningocele the size of a large hen's egg. Extensive involvement of the spinal cord had caused a spastic paraparesis. Her right leg and several toes of her left foot had been amputated. She had dementia praecox with depressive and paranoid features, and was almost continuously disturbed. She was noisy and threw dishes and similar objects at nurses and doctors. Numerous consultations were had for two years, since we hesitated about giving her shock therapy. Finally, when her mental condition became worse and tube feeding had to be given frequently, a course of electroconvulsive treatment was started. Up to this writing the patient has received twenty treatments with no physical ill effects and marked mental improvement. Although some paranoid trends are still present she is well behaved and laughs and talks with everybody who comes to see her.

### MENSTRUATION AND PREGNANCY

Normal menstruation is no contraindication to the treatment. Only when the hemorrhage was profuse did we wait until it diminished. In the literature are several reports of pregnant women who received electroshock treatment without damage to mother or child.<sup>1</sup> We had no pregnant women in our series.

### DIABETES MELLITUS

Five patients had diabetes mellitus, 1, a woman of sixty with a manic psychosis, had blood sugar values up to 275 mg per 100 cc. She had an excellent remission after nine shock treatments. She, as well as the other diabetic patients, withstood electroshock therapy without untoward physical effects.

### SUMMARY

The physical risks of electroconvulsive therapy are discussed on the basis of a material of 8082 treatments received by 628 patients. Thirty-one of them were over sixty, and 5 over seventy years of age. All these patients responded well to the treatment, as did a child of eleven. Even severe undernutrition is no contraindication to the treatment.

About 50 patients had signs of cardiovascular diseases, such as arteriosclerosis, enlargement of the heart, abnormal electrocardiographic findings, rheumatic heart disease and hypertension. One had definite signs of coronary-artery disease, and another a severe congenital abnormality of the heart. In many patients, the increased blood pressure went down when agitation subsided as a result of electroshock therapy. In a few other cases, the blood pressure went up or up and down in a way that was not always consistent with the patient's emotional state.

Eight patients with active and 25 with arrested pulmonary tuberculosis were treated in this series. Shock therapy of mental patients who are suffering from tuberculosis carries definite risks, but in selected cases, electroshock therapy has to be given even if the tuberculosis is active. If there is a history of recent hemorrhage or if the activity is high, shock should be given only when the pulmonary process has been controlled by collapse therapy. In 1 case electroshock therapy and pneumothorax were applied simultaneously.

Patients suffering from acute infections should be excluded from electroshock treatment, and every effort should be made to discover intercurrent infections prior to and during a course of electroshock. This was emphasized by the one fatal case after electroshock therapy that occurred in this series.

Eleven cases of fractures due to electroshock treatment were observed, 2 of them occurred in patients who had bone disease prior to the treatment. All fractures healed without permanent damage. Regarding the preliminary administration of curare, the opinion is expressed that the danger of this drug outweighs its advantage.

A few patients with diseases of the central nervous system were treated without ill effects. Another patient, who had no abnormal physical findings prior to electroshock treatment, developed a

result, routine roentgenologic studies of this age group were discontinued. After 1931, the use of stereoscopic films was also dropped since nothing significant could be detected on one film of a stereoscopic pair that was not equally discernible on the other. X-ray examination of nonreactors was found to be noncontributive, and it too was discontinued. Myers stressed the fact that children showing positive tuberculin reactions should be followed for many years with careful checkups. He recommended that no one attempt to make a conclusive diagnosis by an x-ray shadow and decried the possibility of determining the activity of a tuberculous lesion by a single x-ray examination.

It is of interest to note that in Minneapolis the tuberculin test is used as the method of screening in preference to x-ray examination, whereas in China it has been found that tuberculosis is so prevalent that x-ray films are preferred to the tuberculin test.<sup>42</sup>

Reinfection tuberculosis does not always make its first appearance in the upper lobes. Cherry<sup>43</sup> reports that in 1379 known cases of reinfection 152 per cent were discovered to have had a basal onset of the disease. In a survey of 500 cases with skeletal tuberculosis, Mann<sup>44</sup> found that 57 per cent had active pulmonary tuberculosis. He concluded that the skeletal lesion in most children originated soon after the primary infection, whereas in adults it was usually due to reinfection of a previously quiescent focus, which resulted in blood-stream dissemination and subsequent implantation in the bone and lung. Flaxman<sup>45</sup> advocates the use of a modified posterior lordotic projection, sometimes spoken of as the "apical view," for early recognition of tuberculosis in the apical portions of the upper lobes. This position enhances the visualization of the apexes by displacing the shadows of the clavicles away from the area to be studied. Medlar,<sup>46</sup> in an anatomic investigation of lungs of persons who had died unexpectedly, reports that apical scars were present with equal frequency in those who exhibited no microscopical evidence of pulmonary tuberculosis and in those with single and multiple foci. He believes that apical caps are not necessarily related etiologically to tuberculous infection. In tuberculosis, apical scars occur rarely in persons under the age of thirty, over the age of fifty, they are quite frequently due to tuberculosis, and an inequality of these shadows on the two sides should suggest the possibility of a tuberculous lesion.

That bronchial occlusion often accompanies tuberculosis is stressed in at least two reports. Hutchison<sup>47</sup> believes that the extensive shadows seen in primary tuberculosis are due to collapse and do not indicate pneumonic consolidation. Occlusion of the bronchus is most often caused by enlarged lymph nodes in association with sticky mucus from a swollen hyperemic mucous mem-

brane. Guggenheim,<sup>48</sup> investigating pulmonary emphysema and tuberculosis, comes to the conclusion that in only a small minority of the cases can changes be explained on a purely compensatory basis. Localized emphysema, blebs and bullae are due to bronchial changes, the obstruction of the bronchi and bronchioles is caused by exudate, necrotic material, endobronchial tuberculosis, compression, torsion and stretching.

Considerable literature is accumulating that tends to indicate that many of the multiple areas of calcification seen within the lungs are secondary to histoplasmosis rather than to tuberculosis.<sup>49-51</sup> This conclusion is based on a negative tuberculin reaction and a positive reaction to histoplasmin. It is thought that histoplasmosis has a tendency to show the following features: the presence of multiple lesions in the parenchyma, the rather frequent occurrence before the age of one year, and progression of the pneumonic infiltration with the development of new lesions and appearance of calcification over a period of years. It is believed that a far greater number of children, particularly in the Middle West, are sensitive to histoplasmin than to tuberculin. Holt<sup>52</sup> reported the radiologic appearance of the chest in 5 autopsied cases of fatal histoplasmosis. These findings were exceedingly variable. 1 case showed miliary parenchymal lesions with hilar adenopathy; in another, patchy pneumonitis was present; in a third, a large area of consolidation was found in the right upper lobe; a fourth case showed rather widespread dissemination of miliary lesions; and the fifth disclosed extensive consolidation of the right lung. These findings indicate that there is no characteristic roentgenologic appearance to be expected in active histoplasmosis.

Torulosis,<sup>53</sup> aspergillosis,<sup>54</sup> nocardia asteroides infection<sup>55</sup> and the pulmonary manifestations of amebiasis<sup>56</sup> have no typical appearance and are often confused with tuberculosis (or tumor). Another more common chest condition, likewise difficult to distinguish from tuberculosis, is pulmonary coccidioidomycosis.<sup>57-59</sup> Although it has been considered more or less endemic in the Southwest and West, numerous cases of the infection are being found throughout the country in former members of the armed forces. Many of the initial infections are asymptomatic. In symptomatic cases, it has been noted that the onset is often abrupt, resembling an acute respiratory infection. The early roentgenologic picture may be similar to that of an atypical or bacterial pneumonia, the process may be lobular or lobar and enlarged hilar lymph nodes may be present. Occasionally, pleural effusion may accompany and obscure the underlying process. Nodular densities may appear that ultimately break down and form cavities. Resolution, which may take place in from one to three weeks, is some-

structures are visualized on the film than is possible with films of greater contrast. Although the lateral view has long been stressed as necessary, it is still too often neglected. If one is to visualize satisfactorily the septums and locate the various segmental lesions, it is vital to have a lateral projection.<sup>4, 5</sup> Fleischner<sup>18</sup> has recently called attention to the value of the visible bronchial tree on conventional films as indicating pneumonic and other pulmonary consolidations—in other words, if the bronchi are visible, it is indicative of consolidation or a similar process within the adjacent lung, and their visibility distinguishes the abnormality from a pleural effusion or thickened pleura. Intrapulmonary collections of fluid may be readily confused with an elevated diaphragm,<sup>19, 20</sup> and it may be necessary to examine the patient by means of films taken in the lateral decubitus position or after pneumoperitoneum or pneumothorax.

Numerous ways of obtaining satisfactory bronchograms,<sup>21-22</sup> including aspiration, catheter injection and injection under bronchoscopic control,<sup>24</sup> are available. The most important factor from the radiologic standpoint is that the major bronchi of all the lobes be filled in the average case, or that selected bronchi be filled in the special case. The position of the patient during the flow of the oil is of extreme importance. Kooperstein and Bass<sup>25</sup> call attention to 2 cases of bilateral pneumonia following instillation of lipiodol, this complication, however, is unusual.

Laminagraphy, planigraphy and tomography have received a great deal of emphasis in the past few years.<sup>26-29</sup> These procedures are of value in cases in which the patient is not to be bronchoscoped. They may help in demonstrating narrowing or obstruction of the major bronchi, in differentiating enlarged lymph nodes from hilar vascular structures and in disclosing certain cavities. In some cases peripheral masses, when they are benign, may be shown to displace bronchi and vessels, whereas malignant lesions do not displace the bronchi and if they invade the bronchi the latter are narrowed or occluded. Often, the actual tumor within the trachea or bronchus can be clearly delineated, but such a tumor will not be distinguishable from any other mass present within these structures. Laminagraphy can frequently replace bronchography and bronchoscopy when these procedures are impossible, the usual projections, including posteroanterior and lateral, can be used. Amisano<sup>30</sup> utilized transverse laminagraphy of the chest. The patient is in a sitting position with the head flexed on the chest and the film is under the thighs, the axis of rotation of the laminagraph is at the level of the chest to be examined. Considering the long object-film distance the laminagraphs reproduced were surprisingly good.

A recent suggestion for better delineation of chronic draining empyema cavities is mentioned although they are seen less frequently today than in the past, this is the use of a solution of 50 per cent pantopaque (iodophenylundecylate).<sup>31</sup>

Despite all the advances in technical methods, there still remains a large group of lesions that are not yet readily visualized on the roentgenogram. It has been our experience, confirmed by Ritter and Pendergrass,<sup>32</sup> that many of the small lesions of tuberculosis and metastatic nodules even as large as 1 cm in diameter, particularly if they lie against the pleura, may be invisible on the x-ray film.

Mass chest surveys have proved valuable in the discovery of unrecognized cases of tuberculosis and other processes within the chest. A fair trial of photofluorography was given during World War II and is being continued at the present time. Numerous reviews stressing the value of these routine screening methods have been published, approximately 2 to 9 per cent of the films have disclosed pulmonary abnormalities, as many as 5 per cent of which have been found to be due to reinfection of pulmonary tuberculosis. Repeated surveys in industry and elsewhere have shown that active pulmonary tuberculosis developed as a rule at the expected yearly rate, in suspicious cases, serial observations often confirmed the belief that active minimal tuberculosis is asymptomatic and can be discovered only by radiography of the chest.<sup>33-40</sup>

It should be borne in mind that photofluorography is a purely survey procedure rather than one that has accurate diagnostic value. Even with close attention to the use of proper developers, correct type of film and screen to provide excellent contrast and detail, these surveys cannot yield the information furnished by a complete roentgenologic examination of the chest. Another fact to be remembered is that this form of study will pick up many lesions for which the proper method of treatment may constitute a difficult problem for the internist, the radiologist and the surgeon.

#### DIAGNOSIS OF INFLAMMATORY LESIONS

Myers,<sup>41</sup> in a comprehensive article, reviewed the experience of twenty-six years' observation in the city of Minneapolis. The results demonstrated that carefully planned, long-term studies must be undertaken to evaluate such a chronic disease as tuberculosis. As far as the development of radiologic procedures is concerned, the paper films used at first have been succeeded by photofluorographic methods. In the early years there was considerable discrepancy between the findings on x-ray examination and those on tuberculin testing. After ten years, it was found that x-ray inspection of the chest rarely revealed evidence of significant disease in children under twelve or fourteen years of age even though they reacted positively to tuberculin, as a

result, routine roentgenologic studies of this age group were discontinued. After 1931, the use of stereoscopic films was also dropped since nothing significant could be detected on one film of a stereoscopic pair that was not equally discernible on the other. X-ray examination of nonreactors was found to be noncontributive, and it too was discontinued. Myers stressed the fact that children showing positive tuberculin reactions should be followed for many years with careful checkups. He recommended that no one attempt to make a conclusive diagnosis by an x-ray shadow and decried the possibility of determining the activity of a tuberculous lesion by a single x-ray examination.

It is of interest to note that in Minneapolis the tuberculin test is used as the method of screening in preference to x-ray examination, whereas in China it has been found that tuberculosis is so prevalent that x-ray films are preferred to the tuberculin test.<sup>42</sup>

Reinfection tuberculosis does not always make its first appearance in the upper lobes. Cherry<sup>43</sup> reports that in 1379 known cases of reinfection 152 per cent were discovered to have had a basal onset of the disease. In a survey of 500 cases with skeletal tuberculosis, Mann<sup>44</sup> found that 57 per cent had active pulmonary tuberculosis. He concluded that the skeletal lesion in most children originated soon after the primary infection, whereas in adults it was usually due to reinfection of a previously quiescent focus, which resulted in blood-stream dissemination and subsequent implantation in the bone and lung. Flaxman<sup>45</sup> advocates the use of a modified posterior lordotic projection, sometimes spoken of as the "apical view," for early recognition of tuberculosis in the apical portions of the upper lobes. This position enhances the visualization of the apexes by displacing the shadows of the clavicles away from the area to be studied. Medlar,<sup>46</sup> in an anatomic investigation of lungs of persons who had died unexpectedly, reports that apical scars were present with equal frequency in those who exhibited no microscopical evidence of pulmonary tuberculosis and in those with single and multiple foci. He believes that apical caps are not necessarily related etiologically to tuberculous infection. In tuberculosis, apical scars occur rarely in persons under the age of thirty, over the age of fifty, they are quite frequently due to tuberculosis, and an inequality of these shadows on the two sides should suggest the possibility of a tuberculous lesion.

That bronchial occlusion often accompanies tuberculosis is stressed in at least two reports. Hutchison<sup>47</sup> believes that the extensive shadows seen in primary tuberculosis are due to collapse and do not indicate pneumonic consolidation. Occlusion of the bronchus is most often caused by enlarged lymph nodes in association with sticky mucus from a swollen hyperemic mucous mem-

brane. Guggenheim,<sup>48</sup> investigating pulmonary emphysema and tuberculosis, comes to the conclusion that in only a small minority of the cases can changes be explained on a purely compensatory basis. Localized emphysema, blebs and bullae are due to bronchial changes, the obstruction of the bronchi and bronchioles is caused by exudate necrotic material, endobronchial tuberculosis, compression, torsion and stretching.

Considerable literature is accumulating that tends to indicate that many of the multiple areas of calcification seen within the lungs are secondary to histoplasmosis rather than to tuberculosis.<sup>49-51</sup> This conclusion is based on a negative tuberculin reaction and a positive reaction to histoplasmin. It is thought that histoplasmosis has a tendency to show the following features: the presence of multiple lesions in the parenchyma, the rather frequent occurrence before the age of one year, and progression of the pneumonic infiltration with the development of new lesions and appearance of calcification over a period of years. It is believed that a far greater number of children, particularly in the Middle West, are sensitive to histoplasmin than to tuberculin. Holt<sup>52</sup> reported the radiologic appearance of the chest in 5 autopsied cases of fatal histoplasmosis. These findings were exceedingly variable. 1 case showed miliary parenchymal lesions with hilar adenopathy, in another, patchy pneumonitis was present, in a third, a large area of consolidation was found in the right upper lobe, a fourth case showed rather widespread dissemination of miliary lesions, and the fifth disclosed extensive consolidation of the right lung. These findings indicate that there is no characteristic roentgenologic appearance to be expected in active histoplasmosis.

Torulosis,<sup>53</sup> aspergillosis,<sup>54</sup> nocardia asteroides infection<sup>55</sup> and the pulmonary manifestations of amebiasis<sup>56</sup> have no typical appearance and are often confused with tuberculosis (or tumor). Another more common chest condition, likewise difficult to distinguish from tuberculosis is pulmonary coccidioidomycosis.<sup>57-59</sup> Although it has been considered more or less endemic in the Southwest and West, numerous cases of the infection are being found throughout the country in former members of the armed forces. Many of the initial infections are asymptomatic. In symptomatic cases it has been noted that the onset is often abrupt, resembling an acute respiratory infection. The early roentgenologic picture may be similar to that of an atypical or bacterial pneumonia, the process may be lobular or lobar, and enlarged hilar lymph nodes may be present. Occasionally, pleural effusion may accompany and obscure the underlying process. Nodular densities may appear that ultimately break down and form cavities. Resolution, which may take place in from one to three weeks, is some-

times complete, leaving no scar, at other times, there is healing with fibrosis. In the disseminated form, the roentgenologic appearance may resemble other fungous infections, sarcoidosis, miliary tuberculosis or lymphatic spread of metastatic cancer throughout the lungs. The most common error in differentiation is with tuberculosis.

Boyer<sup>60</sup> reported 50 unselected cases of pulmonary tuberculosis in which bronchoscopy was done. Bronchiectasis was demonstrated in 85 per cent, in some cases it had not been suspected clinically. Collapse treatment seemed to bear no relation to the incidence of bronchial dilatation, and the degree of bronchiectasis had no apparent bearing on the amount of sputum.

Some interesting observations on the occurrence of bronchiectasis that was either associated with or the result of a primary tuberculosis were made by Jones and his associates.<sup>61</sup> In 85 of 716 children with pulmonary tuberculosis, a dense homogeneous, and usually segmental or lobar, shadow suggested the presence of an obstructive pneumonitis. Forty-two of the 85 patients were examined bronchoscopically, and 31 were found to have tuberculous involvement of a bronchus in the form of ulceration, granulation tissue, tuberculoma or extrinsic pressure from enlarged lymph nodes. Several years later some of the same children, together with others showing the same phenomena, were studied by bronchography. In 34 of the 37 children examined satisfactory bronchograms were obtained, and in 24 of these bronchiectasis was evident, the pulmonary lesion had been present twelve months or less in 4 of the latter and for thirteen months or longer in the other 20. The bronchographic examination was done at a mean interval of three and a half years after roentgenologic evidence of clearing of the original lesion. From these observations, it was concluded that the duration of the disease was important in the development of bronchial dilatation and that the damage was permanent. There was a preference for localization of the bronchiectasis to the anterolateral branch of the upper-lobe bronchus and the apical branch of the lower-lobe bronchus. The children had symptoms representing both the primary complex and bronchiectasis, but after clearing of the pneumonitis and tuberculosis, there were few symptoms of bronchiectasis.

Bronchiectasis as an entity has received a large amount of study and comment in the past, and since many cases are surgically curable it is desirable that the diagnosis be made promptly. It is the opinion of many that bronchograms are a necessity in making the diagnosis,<sup>62</sup> whereas Good<sup>63</sup> points out that in 75 per cent of the cases it is possible to make a tentative diagnosis of bronchiectasis from the plain films. He cautions also that it may be suspected more frequently from the routine films than can be confirmed by bronchography. Certain

plain films will show no evidence of bronchiectasis even though the disease is actually present, and Good believes that bronchography is necessary in patients who give clinical evidence of it even though no lesion is demonstrable on the plain films. (Usually, it is best that bronchography be instituted at the request of the surgeon who is to perform the operation, inasmuch as the diagnosis will probably have been established by the plain films and the chief object of bronchography will be to furnish the surgeon with an adequate map of the bronchial tree from which he can plan his attack. This procedure also gives him the most accurate means of follow-up studies of the patient in the years to come. Bronchography, performed merely as a diagnostic method without intent of immediate operation, may leave considerable residua within the lungs, which will interfere with follow-up examination.)

Although there is no intention of entering the controversy regarding whether atypical pneumonia causes bronchiectasis, reversible or irreversible, it is to be noted that some cases of bronchiectasis are first discovered during or after an attack of atypical pneumonia.<sup>64</sup> In cases in which the question whether bronchiectasis is associated with the persistence of a pneumonic infiltration arises, it is probably advisable to do bronchography and to follow it with a second bronchogram after a suitable length of time. Royce and Victor<sup>65</sup> believe that an interval of one to three months is sufficient length of time in which to determine the reversibility of the process. Spain and Lester<sup>66</sup> report a case in which bronchiectasis developed distal to a foreign body in a bronchus within a period of seven weeks. It is their belief that early destruction of the musculoelastic layer precludes the possibility of reversibility.

It is of considerable interest that the radiologist sees relatively few cases of lobar pneumonia due to the pneumococcus in this era of antibiotics. Apparently, most of these patients are being treated in the home and are not hospitalized to any extent. As far as diagnosis of lobar pneumonia or of other inflammatory conditions is concerned it is important that the physician follow the patient until the lesion has cleared roentgenologically. It is surprising how many chronic diseases such as bronchiectasis and numerous tumors are first diagnosed as lobar pneumonia or some other inflammatory condition, later, as the symptoms become more severe, these diagnoses must be discarded.

That the roentgenologic appearance of atypical pneumonia may be somewhat bizarre and easily confused with other conditions is a well known fact. Atypical pneumonia may produce collapse rather than consolidation as demonstrated on the roentgenogram, it can cause lesions that involve the greater portion of an entire lobe, one or more segments of a lobe or a diffuse miliary process.

throughout the lung fields. In the last type, the patient is usually seriously ill, and in some cases this diffuse mottling may indicate the beginning of resolution in a process that had shown widespread consolidation. The lateral view is essential to determine adequately the segments involved as well as the amount of atelectasis that is often associated with the disease.<sup>67-70</sup> The pulmonary type of tularemia and Q fever may produce small areas of pneumonitis, which roentgenologically may be confused with pneumonia.<sup>71-75</sup>

A condition that has received renewed interest in the past few years is Loeffler's syndrome.<sup>76-79</sup> The roentgenologic appearance is thought to be due to areas of infiltration or edema that are transitory and tend to migrate to various parts of the lung. No particular lobe is predominantly involved, although when the upper lobe is the seat of the process it may be mistaken for tuberculosis. Clinically, the patients are usually not very ill, a marked eosinophilia is present, and the sputum may contain eosinophils. Loeffler's syndrome may be associated with infestation by *Ascaris lumbricoides*, *Necator americanus* and *Endamoeba histolytica*, strongyloidiasis, allergies, chronic brucellosis and other diseases. As seen in the tropics, the appearance from the roentgenologic standpoint is frequently unique in that it produces a diffuse miliary appearance, which is of transient duration.

Harvey<sup>80</sup> reports 2 cases of clinically proved brucellosis that showed a tendency to multiple small nodular lesions throughout the lung fields. One patient was known to have had previous bilateral hilar-lymph-node enlargement. The radiologic appearance of the chest is very similar to that usually seen in sarcoidosis. McCort et al.<sup>81</sup> describe the findings in the latter condition. Enlargement of the paratracheal lymph nodes was found in all of the 28 cases comprising their series, with enlargement of the peribronchial lymph nodes in 25, pulmonary or parenchymal involvement was evident in 15. In 2 cases there was pleural effusion, and in 1, pericardial effusion, osseous changes were noted in the hands of 6 patients.

Numerous causes of emphysema and pulmonary fibrosis are known. In a recent symposium on so-called idiopathic fibrosis and emphysema, Mallory<sup>82</sup> has shown certain granulomatous or sarcoid-like lesions to be the inciting factor in a small group. The roentgenologic appearance of these cases differs considerably from the usual sarcoid findings, the markings are greatly thickened throughout the lungs, with large areas of intervening rarefaction, apparently representing emphysematous blebs or bullae.<sup>83</sup> Cases of idiopathic fibrosis run a rather severe course with a fatal termination.<sup>84</sup>

Acute pulmonary edema, a frequent accompaniment of acute nephritis, mitral stenosis and certain other conditions, produces fairly characteristic roentgen-ray shadows. In spite of the minimal

signs and symptoms noted clinically, the radiographs usually show massive centrally distributed shadows in the lungs and a somewhat butterfly-like appearance. Doniach<sup>85</sup> ascribes uremic edema of the lungs to capillary permeability and says that it may be seen in other conditions causing heart failure. According to Burford and Burbank,<sup>86</sup> pulmonary edema in some cases is caused by blast injury in which a wave of highly compressed air produces severe changes in the parenchyma, the pleura and even the chest wall. Under these circumstances, the edema in all likelihood is traumatic and not the result of heart failure.

The appearance and technic of demonstration of pulmonary infarcts has been reviewed by Robbins.<sup>87</sup> An interesting but small group of cases are those in which there is infarction of an entire lobe such as that discussed by Rawson and Cocke.<sup>88</sup> Their patient, a thirty-nine-year-old Negro, had complete infarction of the left lower lobe subsequent to long-continued passive congestion, there was aseptic softening, with subsequent rupture into the pleural cavity resulting in hemopneumothorax. They found only 5 other cases of this type previously reported, and it is of interest that all the patients were between twenty and forty-four years of age.

#### PULMONARY LESIONS IN CHILDREN

An excellent approach to the subject of pediatric pulmonary roentgenology has been presented by Blair.<sup>89</sup> He summarizes and classifies in a concise manner the numerous conditions that may be encountered in children.

The surgical aspects of staphylococcal pneumonia in infancy and childhood have been discussed by Blumenthal and Neuhoof.<sup>90</sup> The roentgenologic appearance is that of ordinary suppurative pneumonia, with densities that may be lobular, lobar or segmental in type and with a tendency to cavitation and abscess formation, there may be extension to the pleura. The authors believe that repeated roentgenologic examination is essential in following the course of the disease.

Another form of cavity, termed pneumatocele, presents a thin margin and may contain fluid. It is seen in the course of other types of pneumonia in children and has recently been re-emphasized by Almklov and Hatoft.<sup>91</sup> The pneumatocele develops in an area of consolidation, the time of its appearance, in the authors' series, varied from the second to the twenty-fifth day after onset of the disease. In certain cases more than one pneumatocele were present, these ranged in diameter from 1 to 3 cm., and fluid levels were frequently noted. The pneumatoceles disappeared spontaneously without treatment.

Of particular interest to the radiologist may be the child who is brought for examination of the chest with the question, because of his cyanosis, of pneumonia or heart disease. Recent reports<sup>92-93</sup>

describe such a condition, which has been found to be due to poisoning from wax crayons. These children exhibit rapid respirations, some elevation of temperature and pulse, weakness and listlessness. The striking roentgenologic feature is the apparently normal chest and the finding of opaque material in the stomach and intestinal tract.

Idiopathic pulmonary hemosiderosis or essential brown induration of the lungs has been described by Wyllie et al.<sup>94</sup> All the patients were children ranging in age from a few months to sixteen years, with the exception of 1 man of thirty-eight years. The disease is characterized by recurrent attacks, sudden in onset, of fatigue, cyanosis and pallor, with increasing dyspnea, acceleration of the pulse rate and a high fever. Cough is troublesome, often followed by vomiting, and at times traces or even considerable quantities of blood are noticeable in sputum or vomitus. There may be abdominal pain as well as increased liver dullness and splenomegaly. The most common roentgenologic findings—and these become accentuated during an attack—are mottled shadows, particularly noticeable in the hilar areas, and a diffuse stippling throughout the lung fields. There may be evidence of partial lobar collapse. At first glance the milium nodules suggest tuberculosis, but close inspection is said to reveal small, clear, circular spaces surrounded by thickened opaque walls, giving a pumice-stone appearance, the heart shadow is enlarged, the border extending chiefly to the right, and the pulmonary conus is prominent. The prognosis is poor.

A somewhat similar type of nodular lesion may be associated with mitral stenosis, and in long-standing cases actual calcification or ossification of some of these nodules may occur.<sup>95</sup>

#### OCCUPATIONAL DISEASES

Occupational diseases that cause changes within the chest are numerous. Some of those reported recently have been associated with welding and inhalation of graphite dust and of dust caused by the handling of grains and seeds.<sup>96-101</sup> Bagasse disease of the lungs, or bagassosis, is brought about by the inhalation of dried bagasse dust. There seems to be an insufficient amount of silica present in the dust to cause the signs and symptoms.<sup>102-103</sup> The severity of the disease appears to be directly related to the concentration and duration of exposure to the dust. Some cases end fatally. The roentgenographic appearance differs from that in other forms of pneumoconiosis primarily in that it is reversible, and resolution may be complete in six to eight months.

Exposure to beryllium compounds in industry has attracted considerable attention in the last few years.<sup>104-105</sup> There appear to be two forms of reaction to exposure, the first of which is an acute chemical pneumonitis resulting from exposure to

high concentrations of beryllium compounds including fluoride, oxyfluoride and oxides. There is a definite relation between exposure and the development of the disease, and if the patient recovers, the symptoms clear up with elimination of the exposure. The second form is a delayed chemical pneumonitis, apparently caused by exposure to small amounts of beryllium compounds in the air. This is characterized by delay, which may vary from one month to five years, between exposure and onset of symptoms. The x-ray appearance, as described by Wilson,<sup>106</sup> is very similar to that seen in sarcoidosis.

#### TUMORS

In the present era of thoracic surgery, the roentgenologic diagnosis of tumor of the lung, in an attempt to differentiate benign and malignant lesions, has become primarily of academic interest.<sup>110-113</sup> Bloch et al.,<sup>114</sup> pointing out the difficulties in differential diagnosis of bronchiogenic carcinoma, observe that diagnosis is often impossible by conservative methods and that surgical exploration is indicated. Churchill<sup>115</sup> states that the problem in primary cancer of the lung is the same as that encountered in any other form of cancer—in other words, earlier diagnosis. In his opinion, roentgenologic screening is at present the only way to detect early primary cancer in the apparently well population. This method will disclose silent neoplasms in the periphery of the lung, and in recent years it has succeeded in bringing to light a few asymptomatic cases. It will not, however, disclose the early endobronchial growth that has not yet encroached upon the lumen of the bronchus; these lesions are less likely to be silent, the patient having symptoms at an earlier stage than the one with a peripheral lesion.

Rigler and Kelby<sup>116</sup> have re-emphasized the fact that obstructive emphysema is a valuable early sign of bronchiogenic cancer. This is best demonstrated by roentgenograms during expiration or by fluoroscopy. Transition from emphysema to atelectasis occurs as the tumor grows and completely obstructs the bronchus. Reitz<sup>117</sup> and Oechsh and Olson<sup>118</sup> stress the necessity of adequate x-ray examination as well as the importance of photofluorography. In their opinion, laminagraphy is of definite value when the lesion is beyond the reach of the bronchoscope.

Gerstl and his colleagues<sup>119</sup> discuss 7 cases of coexisting bronchiogenic carcinoma and pulmonary tuberculosis, noting that there was little difficulty in making the diagnosis of tuberculosis but much in that of carcinoma. The x-ray examination was of the greatest assistance in raising the question of cancer. Hilar enlargement or infiltration, evidence of major bronchial obstruction, or a relatively circumscribed mass should, in the authors' experience, arouse the suspicion of carcinoma.

Lymphatic spread of carcinoma throughout the lungs may produce an appearance that is difficult to differentiate from sarcoidosis, silicosis and other primary lesions. Clinically it is characterized by severe, increasing dyspnea in a patient with recognized or unrecognized carcinoma elsewhere.<sup>120-121</sup>

MEDIASTINAL TUMORS

Numerous tumors of the mediastinum are found incidentally on pre-employment or survey examinations. Frequently cases of myasthenia gravis are found to be associated with thymic tumors, and any patient with this disease should have a thorough roentgenologic study of the chest. Bronchiogenic cysts and cysts arising from the gastrointestinal tract are often observed, these cannot readily be differentiated from malignant teratomas, neurofibrosarcomas and other malignant tumors.<sup>122-127</sup> In the differential diagnosis, one should exclude the possibility of aneurysm of the aorta, and this may be done by angiocardigraphic visualization of the heart and great vessels.<sup>128</sup> An intrathoracic meningocele must also be distinguished from neurogenic tumors, this may be accomplished by myelography or possibly by the utilization of the Valsalva test during fluoroscopy.<sup>129</sup> Holt<sup>130</sup> called attention to right-sided epicardial fat pad as a differential point, these may be found in the right anterior costophrenic angle. Often, however fat pads cannot be distinguished from cystic lesions, omental hernias or tumors in this location. The facts that malignant changes cannot be excluded in any mediastinal tumor and that there may be later infection of cystic lesions make it imperative that surgical removal be attempted whenever possible.

SUMMARY

Methods for the roentgenologic diagnosis of pulmonary lesions are steadily improving. There remain, however, a large number of unsolved problems that offer a wide field for future investigation.

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

### CASE 34471

#### PRESENTATION OF CASE

*First admission* A seventy-one-year-old woman was admitted to the hospital because of the presence of an abdominal mass.

Eight years before admission the patient noted a walnut-sized mass in the right lower quadrant, which gradually increased in size. Six months before admission she first noted pain at the upper portion of the mass. There was no fever, chills, nausea, melena, night sweats or urinary symptoms.

Physical examination showed some tenderness in the right lower quadrant. A mass was palpable extending laterally into the right flank, and it was felt extending on to the crest of the ilium.

Laboratory examination revealed a negative urine, a white-cell count of 8000 and a hemoglobin of 13.5 gm. A barium enema showed diverticulosis of the sigmoid and upward displacement of the cecum by a large soft-tissue mass in the right lower quadrant. The terminal ileum lay along the medial and inferior margins of the mass.

At operation there was an encapsulated tumor attached to the ureter, bladder, appendix and the large vessels running to the right leg. In removing the tumor the right common iliac artery gave way and it was necessary to ligate it. Following operation she was treated with anticoagulants and exercises, and the leg remained viable. The pathological report on the tumor was fibroma, probably neurogenic.

*Second admission* (two years later) The patient remained well until three and a half months before admission, when she suffered an attack of "grippe." She did not feel that she regained her full strength following this illness and one month later she noted a yellow color to her skin. This was not associated with an acute episode of pain or nausea and vomiting. She did notice postprandial distress associated with belching, a feeling of fullness and bloating. The stools were light, and the urine dark, and there was generalized itching. In the two weeks prior to admission the jaundice lessened in degree and the stools became

darker and the urine lighter. Bilateral ankle swelling was noted.

On examination the blood pressure was 130 systolic, 80 diastolic. The main finding was an abdominal mass with an irregular edge, occupying the right upper quadrant, extending 15 cm below the costal margin. The skin was icteric, and there was ++ edema up to the knees. The temperature was normal.

Laboratory examination revealed a urine specific gravity of 1.017, a + test for albumin and a +++ test for bile, and microscopically there was an occasional white cell and granular cast in the sediment. The white-cell count was 8600, and the hemoglobin 12.5 gm with a normal differential. The van den Bergh test was 10.3 mg per 100 cc direct and 13.2 mg indirect, the prothrombin time was 17 seconds (normal, 16 seconds), and a cephalin flocculation test was ++ at the end of twenty-four and forty-eight hours. The total protein was 6.72 gm, the albumin 3.7 gm, and the globulin 3.01 gm per 100 cc, and the alkaline phosphatase was 24.6 units. A barium enema showed displacement inferiorly of the transverse colon and cecum by a large mass believed to be liver. A gastric series revealed displacement of the stomach and duodenum to the left by a mass in the right upper abdomen. A chest radiogram disclosed a rounded area of increased density, 1.5 cm in diameter, in the left lower lobe, not present two years previously. An intravenous pvelogram demonstrated good function in both kidneys. A retrograde pvelogram showed a normal kidney on the right.

On the eighteenth hospital day a laparotomy was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. CLIFFORD C. FRANSEEN: May we see the x-ray films?

DR. JAMES J. MCCORT: A plain film of the abdomen made on the first admission discloses a large, soft-tissue mass in the right lower quadrant. A barium enema shows diverticula in the sigmoid without signs of inflammation. In addition to that the cecum is elevated and a loop of terminal ileum displaced toward the midline, evidently around the mass. It does not appear to be intrinsic.

When the barium enema was done two years later the barium flowed readily from the rectum to the cecum. The diverticula previously described are filled at this time. However, a large mass is present in the right upper quadrant, displacing the transverse colon downward. Again, there is no evidence that the soft-tissue mass is intrinsic to the colon. A gastrointestinal series done on the second admission shows a suggestion of small varices in the lower third of the esophagus. The stomach is displaced to the left and slightly anteriorly, owing to extrinsic pressure. Studies were made to demon-

to suggest any abnormal condition in the stomach. All the x-ray findings suggest pressure extrinsically. If one comes down to an eventual analysis and is forced to choose any particular tumor one might say that this was a malignant tumor of the fibro-cellular group arising in the retroperitoneal structures with metastases to the lung but the metastases to the liver still bothers me. The picture to my mind would better fit something like a new primary tumor in the liver, which could of course go to the lung like this and form this large mass. Nothing is said about ascites. I think we come down to the point where the diagnosis might be academic. One can only prove it by histologic examination. This answer might have been obtained by a peritoneoscopy. Presumably a laparotomy was done with the idea that if the gall bladder was not involved a short-circuiting operation could be done, and the patient could be given some temporary relief from the jaundice. That is as far as I can go toward establishing the histologic diagnosis except to say that the retroperitoneal tumor had apparently involved the liver. If I were to make a choice preoperatively, I would list a primary hepatoma of the liver.

DR. WYMAN RICHARDSON: There is nothing suggested from the history that there was underlying disease of the liver. Usually the primary hepatoma develops on top of it.

DR. FRANSEEN: That is true. The only clue here is the suggestion of esophageal varices.

DR. FRED A. SIMMONS: I operated on this patient at the first admission. She will always remain a graphic case because of the accident to the wall of the internal iliac artery, which was of fairly good size. The tumor encircled the great vessels behind as well as on top. The ureter lay in the curve of the lateral aspect. As the tumor was dissected from the common iliac artery the vessel separated apparently at the site of a calcareous deposit. We altered our technic and the tumor was freed after the hemorrhage had been controlled and transfusion started. The patient's condition was good enough to allow removal of the tumor though we thought we had removed it in its entirety. I am impressed with the careful postoperative handling by the house staff which enabled this woman to keep the extremity. The pathological report was a benign tumor, but my impression at the operation was that it should have been malignant. I could not palpate the liver, since we approached the growth retroperitoneally.

#### CLINICAL DIAGNOSIS

Metastatic fibrosarcoma of liver

#### DR. FRANSEEN'S DIAGNOSIS

Hepatoma of liver

#### ANATOMICAL DIAGNOSIS

*Metastatic fibrosarcoma of liver and lungs*

#### PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: When the patient came back the second time the service asked us to review the slides of the original tumor, which we did, and felt again that from the block we had it looked like a benign fibroma. A peritoneoscopy was unsatisfactory so that a laparotomy was done and a tumor found within the liver, a biopsy of which showed fibrosarcoma. The patient did not do well following that procedure and died.

At autopsy she had a liver that weighed almost 6 kg., being diffusely involved with round nodules

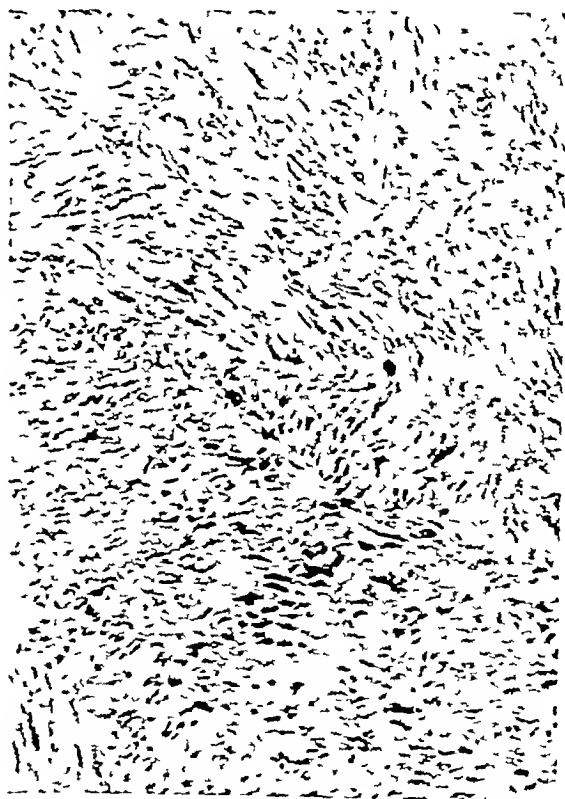

FIGURE 1

of metastatic sarcoma. The metastases were very circumscribed and could easily be shelled out, a feature that distinguishes it from metastatic carcinoma. The jaundice was probably due in part to the neoplastic replacement of the liver, but I believe more likely due to the fact that the caudate lobe was completely involved with tumor and pressed against the common bile duct. There were two nodules in the lungs—one on the pleura of the left lobe and one within it.

strate the right kidney and any possible relation of the mass to the kidney. On an intravenous pyelogram we see a normal outline of the kidney with good filling of the calyces and pelvis and without distortion of these structures. Further study by the retrograde injection of dye in the right urinary tract confirms this. If we compare the films taken on the first and second admissions there is no difference in the appearance of the calyces or in the configuration of the pelvis in two years. We can see the kidney in the later film behind the soft-tissue mass. It is a little lower in the abdomen than it was two years previously. The mass, therefore, is extrinsic to the right kidney and displaces it downward slightly.

There is a small, round area of increased density in the lower lobe of the left lung seen in the chest film taken on the second admission but not present on the chest film taken two years earlier. Otherwise the lungs are clear, the heart and vessels appear normal.

DR. FRANSEEN: Let us go back to the beginning and see what we can make of this tumor. It was evidently one of slow growth and when first noted was a walnut-sized mass in the right lower quadrant. We can tell something about the huge size of the abdomen from the x-ray films. If the patient was able to feel the mass herself through that abdominal wall, we can be sure that the walnut-sized mass was just a knob that protruded above a larger mass beneath. Eight years later she had a large lesion in the right lower quadrant consistent with slow growth. The slow growth was also suggested by the pathological report of a fibroma, possibly neurogenic. We get no exact idea of its site of origin from this record. It was apparently adjacent to or attached to numerous structures. With such soft-tissue tumors, one can cover oneself by saying that, from subsequent events, perhaps a section from another part of the tumor might have shown it to be more malignant than the histologic picture that was reported. In general, in dealing with tumors, if a secondary tumor appears, one should always assume that there was a relation with the first until proved otherwise. It may not have been so in this case. For two years she remained free of trouble. That is not an unreasonable interval for a tumor of this type even though there may have been a recurrence. Although the tumor was reportedly encapsulated, there was considerable difficulty in removing it—that is, it was not clearly encapsulated from a surgeon's viewpoint.

Two years later she had what was thought to be the "grippe," meaning, I suppose, that her family doctor had treated her for "intestinal grippe," and not necessarily an upper respiratory infection. The symptoms related to the stomach could be accounted for on the basis of pressure on the stomach or duodenum since the duodenum was pushed over

to the right on x-ray study. There is no mention of blood in the stools. There is no way of knowing, of course, whether or not this was a second primary tumor, and this always has to be considered. I am assuming all along that this was a tumor. There is nothing to suggest that this was an inflammatory process from the history or the findings at that time, and I think it is safer to go on the assumption that this was a tumor until it has been ruled out, especially in a seventy-three year-old woman. If it turns out to be inflammatory, that is fine. There is nothing here to permit me to suspect that this was due to an inflammatory lesion of the biliary tract or to obstruction on the basis of stone in the common duct. One certainly has to consider that area in the lung as a metastasis and thereby strengthen the suspicion of tumor.

Could all this picture have come from one of the fibrocellular groups of tumors? Metastasis to the liver would be an unusual behavior for it, however. We assume that the palpable mass was the liver, but the mass could have been in the retroperitoneal structures and the lymph nodes, giving the same displacement on x-ray examination, but this would also be somewhat unusual for the type of tumor described, even the malignant forms. The same statement is true of the neurogenic group. In my experience these two often show up in the lung but rarely in the liver. If we dismiss that, we will have to cover ourselves further by saying that it may have been some other form of malignant tumor, possibly a leiomyosarcoma. It would fit in, but not well. So, taking everything into consideration, I think it is safe to assume that a second primary tumor would not be uncommon, especially in a seventy-three-year-old woman.

What primary tumor can cause these findings? We have not much evidence for a malignant lesion anywhere else in the gastrointestinal tract. The jaundice could well have been due to pressure at the hilus of the liver on the bile duct. The only thing I can see against it is that the findings suggest that the jaundice lessened. Almost invariably with malignant tumors jaundice is progressive and becomes complete rather than being intermittent when it is caused by obstruction from a stone. That is the only finding against this idea, however. We must consider other things of course. The whole abdomen is open to suspicion—the gastrointestinal tract and the ovaries, for example. I think we can assume that the breasts and other peripheral sources of origin have been ruled out, or some mention would have been made of them. We assume perhaps that the left kidney was normal. The retrograde pyelogram was done only on the right. Is that correct?

DR. McCORT: Yes.

DR. FRANSEEN: There was no question that function was good in the left kidney. There is nothing

left ureteral orifice. No blood was seen coming from either orifice.

An intravenous pyelogram showed a filling defect measuring approximately 2 cm. in diameter in the left kidney pelvis and in the adjacent inferior major calyx (Fig. 1). In none of the films did the area fill, and one of the calyces was deformed, suggesting the presence of a mass in that region. The lateral margin of the left kidney was not clearly visualized, but there was some suspicion of an increase in size extending outward from the lateral margin in its middle portion. The right kidney was normal in size, shape and position.

On the nineteenth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR. RICHARD CHUTE. To begin with, the fact that this patient was a rubber-factory worker may have been of significance. Although we do not know how long he had been at this work or exactly what he did, the possibility of poisoning with benzol, with an aniline compound or with lead must always be considered in rubber-factory workers. Lead is used in the process of manufacture, benzol is widely used as a solvent, and aniline compounds are employed to accelerate vulcanization. In benzol poisoning the bone marrow is affected, with reduction in platelets and a tendency to abnormal bleeding from the gums, nose and so forth. Frequently there is leukopenia (although the white-cell count may be normal or may be elevated), and there is anemia. In this patient there was no mention of bleeding other than intermittent hematuria, consistent with his bladder tumors, his white-cell count was not remarkable, and there was very little anemia so I believe that benzol poisoning can be ruled out. Also, I feel that lead poisoning can be ruled out, since no colic, weakness, wrist drop, lead line and so forth were mentioned. When it comes to the question of aniline poisoning he was not described as cyanotic like the rubber-factory workers who used to be called "blue boys" in Akron, Ohio. Nevertheless, it is a fact that workers with aniline compounds have a well recognized abnormal tendency to the formation of bladder tumors, which are said to occur in them thirty-three times as frequently as among other people. The tumors usually do not appear until after prolonged exposure—the average time being twelve years. A doubtful privilege of working in plants where a good deal of aniline is used is that of receiving, at the company's expense, periodic cystoscopic examinations. Furthermore, long exposure to aniline is well known to make men irritable and grouchy, and this patient is described as "emotionally unstable." So it is possible that aniline poisoning played a part in this case.

The finding of two pedicled papillary tumors is not surprising in a fifty-five-year-old man with

a history of bladder symptoms and the presence of blood in the urine. In my opinion these are undoubtedly papillary carcinomas, since I know of no other bladder disease that produces this picture. Bilharziasis (schistosomiasis) may produce a somewhat similar appearance, except that the lesions are more sessile and are usually ulcerated, and there are usually more marked symptoms and evidence of inflammation. The finding of only rare white cells in the urine indicates that the lesions in the bladder were not inflammatory. Nothing is said

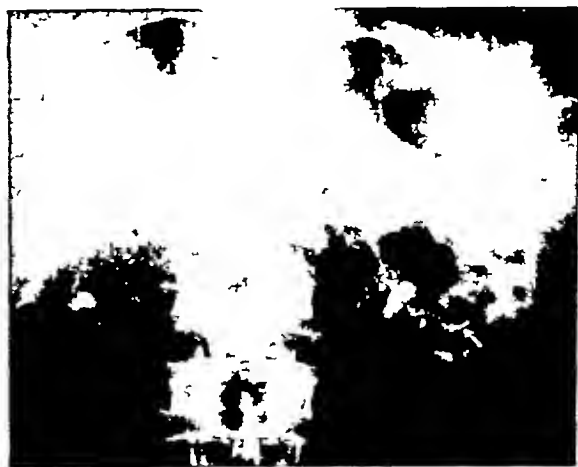

FIGURE 1 Intravenous Pyelogram  
Arrow points to crescentic calyx

about residence in areas of schistosomiasis such as Egypt or of finding the ova of *Schistosoma haematobium* in the urine.

Next we come to consideration of the significance of the filling defect in the left kidney pelvis associated with deformity of a calyx, suggesting a mass. Naturally, from the x-ray reports one thinks at once of a malignant papillary tumor of the kidney pelvis that has invaded the kidney parenchyma. It is well known that papillary tumors of the kidney pelvis often invade the kidney, extend down the ureter and give secondary implants in the bladder. Perhaps the tumors in the bladder were not true implants. Perhaps they occurred simultaneously with the renal tumors, very possibly brought on by the same etiologic factor. At any rate, the association of papillary tumors of the kidney pelvis with papillary tumors of the bladder is a well recognized fact. It is believed that this double lesion is greater in persons exposed to aniline than in others.

The fact that at cystoscopy no blood was seen coming from either ureteral orifice does not rule out the kidneys as a source of bleeding in a case with intermittent hematuria. In this patient the

DR ALLEN G BRAILEY Why did the jaundice lessen?

DR CASTLEMAN Perhaps the caudate lobe flopped around a bit

DR JAMES T HEYL Was there anything left in the right lower quadrant?

DR CASTLEMAN The pelvis was completely free from tumor. The right ureter was thickened on the outside where the tumor apparently had been adherent but there was no evidence of tumor. We

FIGURE 2

took several sections from that area. Here is a photomicrograph of the original fibromatous tumor (Fig 1). It is not very cellular, and the individual cells have single nuclei. In the section of the liver biopsy, on the other hand, the cells have changed. The nuclei are very large, some of the cells have two and three nuclei, and occasional mitoses are seen (Fig 2). It is possible, as Dr Franseen has mentioned, that if more blocks from the original tumor had been taken, we might have found one or two areas with morphologic evidence of malignancy.

DR RICHARDSON Is it possible that this was a new tumor?

DR CASTLEMAN I do not believe so. These certainly were metastases in the liver.

DR FRANSEEN Can you remember how many other times you have seen a fibrosarcoma behave this way?

DR CASTLEMAN I think we have had one other case. However, most of these cases that metastasize go to the lungs.

DR SIMMONS In retrospect, it would have been wise to radiate her.

DR CASTLEMAN No, I do not believe so. The metastases had probably already occurred at the time of the original operation.

DR FRANSEEN I also think that the metastases were there at the time of operation. Again we should emphasize the fact that hepatic metastases alone are not a contraindication to palliative surgery in certain carcinomas and other tumors—for example, cancer of the rectum. In this case it is possible that metastasis to the liver was not recognized at the original operation, and perhaps fortunately so, otherwise there might have been a temptation to abandon the difficult removal, and the patient would thereby have been denied the two years of palliative relief that she obtained.

## CASE 34472

### PRESENTATION OF CASE

A fifty-five-year-old rubber-factory worker was admitted to the hospital because of hematuria.

Approximately five months before entry he began to have intermittent hematuria, with blood clots. This was associated with a low backache and some dysuria. He had no pain in the flanks, loins or lower abdomen. He had nocturia four or five times a night but rarely any urgency. There was no weight loss.

Physical examination revealed a slim, emotionally unstable man who appeared younger than his stated age and who seemed in good physical condition. Aside from a moderately enlarged prostate gland, the physical examination was negative.

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 90 diastolic.

Examination of the blood disclosed a white-cell count of 10,000 and a hemoglobin of 12.8 gm. The nonprotein nitrogen was 32 mg per 100 cc. The urine showed a +++ test for albumin, and the sediment contained 100 to 120 red cells and a rare white cell per high-power field. The specific gravity was 1.015. A urine culture grew *Staphylococcus albus* and alpha-hemolytic streptococcus.

Cystoscopy revealed a small, papillomatous growth, measuring approximately 1.5 cm in diameter, just behind the interureteric ridge. Another round mass, measuring approximately 3 cm in diameter and having what appeared to be a larger stalk, was noted just to the left of the

## TO HIM THAT OVERCOMETH

A SERIES of short papers have appeared this year in the London *Lancet* that are in no sense scientific or technical contributions, nor are they clinical, in that they do not describe from a professional point of view the symptomatology of the disorders discussed, or their treatment. Under the general heading "Disabilities" they consist merely of the patient's own brief chronicle of the disabling features of a disease or an injury, the method of meeting them and the degree of success attained in overcoming them.

The physical means by which some of these disabilities are defeated or their effects mitigated is of interest, the real worth of the articles lies in their

inspirational value — the spiritual lesson that they teach of the strength that comes through the effort of resistance. Each instalment in the series is a chapter from the book of courage.

A girl of twenty-three with a crushed vertebra and a damaged spinal cord copes with the problem of urinary incontinence and forces herself to become again a useful and optimistic member of society. A young man with a lesion of the cauda equina teaches himself to overcome his own bowel and bladder difficulties and learns to walk again. An Englishwoman with disseminated sclerosis, uncoordinated to the point where she reels and staggers like a drunken person, is caught in the German occupation of France. Considered by the conquerors as incapable of resistance she organizes a factory for forging identification papers and with one leg splinted, relearns bicycle riding. Alone she travels through the countryside, picking herself out of the ditch after each of her frequent catastrophes, finds fugitive English and American fivers and arranges for their escape. A victim of the crippling effects of her disease, she apparently finds also some measure of compensation in the emotional exaltation that sometimes accompanies it.

A man with double forearm amputation as a result of a bomb explosion employs to their fullest possibilities the varied mechanical contrivances available for amputees, as well as those that he has himself invented or improved. The best years of his life he finds to be still ahead of him. A patient with congenital cerebral palsy, compounded with infantile paralysis contracted at the age of two, considers life to be a "total war against physical affliction." "When told I cannot do a thing I have sometimes to sit and think out my own way of doing it and then I make this way as much like the normal method as possible." It is this person, once "the peculiar child of all peculiar children" who becomes a lecturer and lay preacher, who teaches himself to ride a bicycle, to drive a car and to manage a horse.

Another victim of a bomb explosion, suddenly and totally blinded at the age of thirty discovers that "one of the compensations of blindness is finding ways of overcoming it." It is this person who, having decided that such recreations as billiards

hematuria could just as well have come from a kidney as from the bladder tumors—very likely from both. Regarding the differential diagnosis of the x-ray picture, blood clot could have caused a filling defect in the kidney pelvis, but I would hardly expect it to deform a calyx or produce a picture suggestive of a mass. However, a tumor with blood clot could give this picture. Other tumors than papillary ones, such as invasive squamous-cell carcinoma of the renal pelvis and, rarely, renal-cell carcinoma (so-called hypernephroma), could also produce this appearance. Renal cyst is another possibility. This could cause deformity of a calyx and the suggestion of a mass, and, if it bled, as they sometimes do, the resulting blood clot could cause a filling defect in the kidney pelvis. Rarely, a staphylococcal abscess of the kidney parenchyma—the so-called renal carbuncle—gives this appearance on x-ray study. In the record no mention is made of the usual preceding history of recurrent furuncles or other infected skin lesions or a paronychia. Also, there was no fever and no mention of pain or tenderness in the left kidney region. The staphylococcus cultured from the urine was *Staph albus* rather than *Staph aureus*, the usual organism in these processes. Therefore, I do not believe that we are dealing with a renal carbuncle.

The final note says that "on the nineteenth hospital day an operation was performed." Since it is most unusual for the Urological Service to wait as long as this to operate, I suspect that there was something very unusual about this case. However, on the basis of the evidence submitted to me, I am making a diagnosis of carcinoma of the left kidney, probably papillary, and papillary carcinoma of the bladder.

DR STANLEY M WYMAN The plain film of the abdomen shows the kidneys fairly well outlined. I am unable to get very much excited about any distortion of the lateral margin of the left kidney. These first three films of the intravenous pyelogram examination are the most striking. There is a crescentic dye shadow overlying the lower major calyx. The appearance is that of compression and displacement of a minor calyx and compression of the pelvis of the kidney. The major calyces, as far as we can see in the upper pole, appear normal. The lowermost calyx and the calyx extending to the left lower quadrant are not adequately seen. From this examination one can assume the presence of a mass, 2 or 3 cm in diameter, compressing the calyces in this region. The last film taken from the retrograde

examination better demonstrates the lower major calyx. I can see no definite intrinsic involvement of this and there seems to be merely pressure on a minor calyx and distortion of the lower major calyx. Again there is possibly a little upward displacement of the major calyx in the midkidney region, giving the impression of something in this region compressing but not intrinsically involving the major calyx. I do not believe that the kidney pelvis per se is involved in this process. I think it is most likely a mass in the parenchyma rather than in the calyx.

DR CHUTE That would throw out papillary carcinoma of the kidney and make a renal-cell carcinoma or cyst a better choice.

#### CLINICAL DIAGNOSIS

Papillary carcinoma of kidney and bladder

#### DR CHUTE'S DIAGNOSES

Renal-cell carcinoma or cyst of kidney  
Papillary carcinoma of bladder

#### ANATOMICAL DIAGNOSES

Cyst of kidney  
Papillary carcinoma of bladder

#### PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN The first operation was a biopsy of the tumor of the bladder. This proved to be papillary carcinoma, and following that operation the left kidney was removed. When we received the kidney we found a well encapsulated, previously sectioned cyst about 2 cm in diameter in the midportion of the kidney, extending down and compressing the calyx to the lower pole of the kidney. The cyst had a very thin wall and apparently had been filled with clear, thin fluid. There was a thin layer of cortex over the cyst wall so that I do not believe it had produced much, if any, bulge of the margin of the kidney.

The patient worked in a factory where rubber products, such as raincoats and boots, are made and not in the manufacture of rubber. I should doubt that he was exposed to beta-naphthol, which is the substance in the aniline dyes that is responsible for the development of bladder cancer.

DR ARTHUR W ALLEN What did they do to the bladder tumor?

DR CASTLEMAN It was resected by cautery just a few days ago.

actual scientific valuation. A high premium goes with surgery, with anesthesia, with injections, with anything that the patient can grasp as presenting some definite procedure. A low premium goes with diagnostic skill, commonsense advice or friendly support. Even medical men, being themselves human, are drawn into the same way of thinking.

In discussing the problem at a meeting a surgeon recently said, "You mean the general practitioner is just a medical man who refers everyone to some specialist who can treat him?" In actual fact the family doctor can and should handle 80 to 90 per cent of the patients who consult him. But to treat them adequately he must be well trained in internal medicine, he must be a very good psychiatrist, and above all he must be as interested in the patient as a person as he is in the disease that the patient possesses. To be all of these surely, is a full-time job, one that does not permit the time to acquire technical skills involved in surgical maneuvers. If economics is the prime obstacle to the attraction of men into this branch of medicine, either the family doctor must be content with a lower financial return than his surgical brother, or a utopia must be reached where all men receive their just deserts.

Recognizing the dangers inherent in the distribution of medical care in the complicated structure of modern medical science the attempt is now being made to organize and classify everyone. The specialty boards have become so important and the possession of a certificate so highly prized that the majority of the medical students in the country are now planning their educational program to become certified specialists. But if only 10 to 20 per cent of the patients need a specialist, such a situation is ridiculous. Obviously, something must be done to point up the importance of the family doctor or general practitioner who should take full care of 80 to 90 per cent of the patients.

The establishment of the Section on General Practice in the American Medical Association and the proposal to organize a board of general practice may be steps in the right direction, but one wonders whether these are not moves based on self defense — a kind of guild or labor-union attitude — rather than a desire to advance medical science.

Would it not be more appropriate to reduce the opportunities for specialization to their proper proportions and at the same time to define clearly where the function of the general practitioner or family doctor lies? In addition, should not greater steps be taken to emphasize in hospital training qualities that the family doctor most needs — sound internal medicine and sound understanding of psychosomatic problems? Should not greater attempts be made to educate the public? If these things can be accomplished, general practice or family doctoring will assume its rightful place of esteem, and he who practices this skill will lose his all too frequent inferiority complex.

---

## DIABETES WEEK

THE week of December 6 has been designated as Diabetes Week, an arbitrary unit of time in which every effort will be made to bring under treatment the estimated million undiscovered diabetic patients in the country. This is not, obviously, a task that can be accomplished in a week; the designation is for the purpose of hammering home the existence of the problem and the necessity of meeting it. Considerable assurance was required, as the counselors of the American Diabetic Association know, to launch another special week for observance. In this case at least the cause was justified, and the need may be considered as imperative.

"The Clinical Characteristics of Early Diabetes Mellitus," by Beaser, printed elsewhere in this issue of the *Journal*, is most timely in view of the task that the American Diabetic Association has set. Beaser's statistics also, taken from the Diabetes Clinic of the Beth Israel Hospital, indicate the prevalence of early diabetes and the undesirability of having it go undetected. The task is to make the public aware of the necessity for the early discovery of the disease before overt symptoms have manifested themselves.

Patients can be classified in three groups according to the nature of the first signs or symptoms by which the disease makes its presence known. In the first group are those with frank diabetic symptoms such as polydipsia, polyuria, weight loss, weakness and pruritus. This group comprises

and table tennis are beyond his capacity, turns successfully to high diving, surf-riding and aquaplaning. For him the words of England's blind poet have had peculiar meaning

who best

Bear his milde yoaik, they serve him best

And so the list has grown — the education of a congenitally deaf child as told by its parents, the adjustments made by a nurse who develops epilepsy at thirty, the problems of the tuberculous, the young man crippled by poliomyelitis, the adolescent boy with an ileostomy, the alcoholic who finds his salvation in helping others similarly afflicted

Overcompensated many of these witnesses may be called, and with reason, as the heart hypertrophies that has an extra load to carry. From their achievements, however, a fundamental lesson may be drawn. All forms of life are meant to struggle against their difficulties and to rise above their obstacles or succumb. These that have been presented are only extreme examples culled from recent experiences.

If man, individually or in the aggregate, cannot accept life's challenges he must accept the futility of life. In this season set briefly apart for gratitude let him, then, rather than being thankful only for what apparent good fortune may seem to have overtaken him, be thankful also for the problems, the adversities, the temporary reverses that challenge him.

"To him that overcometh," it is written, "will I give to eat of the hidden manna."

---

## THE FAMILY DOCTOR AND THE GENERAL PRACTITIONER

THE current discussion regarding the role and prestige of the general practitioner has resulted in a certain amount of confused thinking. Some say that he is on his way out and the sooner the better, for things are done differently nowadays than formerly. Others bewail his decline, realizing that he is the most important cog in the organization for the care of sick people.

What are the reasons for these divergent views? They are concerned with semantics, with economics

and with the American obsession to organize and classify.

As to semantics, there is as much confused thinking in the medical profession as in the laity regarding the meaning of the term general practitioner. For purposes of discussion let us assume that a general practitioner is the first-echelon unit of medical care to whom the patient turns when he falls ill — whether such illness is a fever, vague fatigue and boredom with life, a perforated peptic ulcer or a fractured femur. If the patient lives in a small town situated far from a large city, the general practitioner will care for all the above illnesses. He has to be an astute internist to diagnose the fever, a skilled diagnostician and wise psychiatrist to deal properly with the tired patient, a competent surgeon to diagnose correctly and to operate upon the patient with an acute abdominal emergency, and an able orthopedic surgeon. But if the patient lives in a large city, who can deny that the best care requires that the general practitioner be primarily a medical man, and that surgical techniques are of a higher order when practiced by one doing nothing else but surgery? Here the general practitioner, though still the first-echelon unit of medical care, becomes a family doctor who knows how to diagnose and deal with problems but who refers patients requiring technical procedures and special skills to those who practice such procedures every day. In the small isolated community the family doctor and general practitioner are by geographical necessity one and the same. In the large city the general practitioner required by the small isolated community should not exist — he becomes the family doctor or family medical advisor.

Economics enters into the problem in that human beings put a high value on something that can be seen or felt — something producing quick action. They will gladly pay a large sum to a surgeon to take out an appendix or hitch up a uterus, in a mistaken attempt to cure a gastrointestinal neurosis. But they will feel imposed upon if asked to pay ten or fifteen dollars to a physician who spends an hour discussing personal problems and trying to teach the patient how to deal with them himself. The fact is that compensation for medical services is based on what the public values not

actual scientific valuation. A high premium goes with surgery, with anesthesia with injections, with anything that the patient can grasp as presenting some definite procedure. A low premium goes with diagnostic skill, commonsense advice or friendly support. Even medical men, being themselves human, are drawn into the same way of thinking.

In discussing the problem at a meeting a surgeon recently said "You mean the general practitioner is just a medical man who refers everyone to some specialist who can treat him?" In actual fact the family doctor can and should handle 80 to 90 per cent of the patients who consult him. But to treat them adequately he must be well trained in internal medicine, he must be a very good psychiatrist and above all he must be as interested in the patient as a person as he is in the disease that the patient possesses. To be all of these surely, is a full-time job, one that does not permit the time to acquire technical skills involved in surgical maneuvers. If economics is the prime obstacle to the attraction of men into this branch of medicine, either the family doctor must be content with a lower financial return than his surgical brother, or a utopia must be reached where all men receive their just deserts.

Recognizing the dangers inherent in the distribution of medical care in the complicated structure of modern medical science the attempt is now being made to organize and classify everyone. The specialty boards have become so important and the possession of a certificate so highly prized that the majority of the medical students in the country are now planning their educational program to become certified specialists. But if only 10 to 20 per cent of the patients need a specialist such a situation is ridiculous. Obviously, something must be done to point up the importance of the family doctor or general practitioner who should take full care of 80 to 90 per cent of the patients.

The establishment of the Section on General Practice in the American Medical Association and the proposal to organize a board of general practice may be steps in the right direction, but one wonders whether these are not moves based on self defense—a kind of guild or labor-union attitude—rather than a desire to advance medical science.

Would it not be more appropriate to reduce the opportunities for specialization to their proper proportions and at the same time to define clearly where the function of the general practitioner or family doctor lies? Should not greater attempts be made to educate the public? If these things can be accomplished general practice or family doctoring will assume its rightful place of esteem and he who practices this skill will lose his all too frequent inferiority complex.

## DIABETES WEEK

THE week of December 6 has been designated as Diabetes Week, an arbitrary unit of time in which every effort will be made to bring under treatment the estimated million undiscovered diabetic patients in the country. This is not obviously a task that can be accomplished in a week; the designation is for the purpose of hammering home the existence of the problem and the necessity of meeting it. Considerable assurance was required as the counselors of the American Diabetic Association know to launch another special week for observance. In this case at least the cause was justified, and the need may be considered as imperative.

"The Clinical Characteristics of Early Diabetes Mellitus," by Beaser, printed elsewhere in this issue of the *Journal*, is most timely in view of the task that the American Diabetic Association has set. Beaser's statistics also, taken from the Diabetes Clinic of the Beth Israel Hospital, indicate the prevalence of early diabetes and the undesirability of having it go undetected. The task is to make the public aware of the necessity for the early discovery of the disease before overt symptoms have manifested themselves.

Patients can be classified in three groups according to the nature of the first signs or symptoms by which the disease makes its presence known. In the first group are those with frank diabetic symptoms such as polydipsia, polyuria, weight loss, weakness and pruritus. This group comprises

some 34 per cent of the total. The second group, making up 19 per cent, is composed of those who first become aware of diabetes because of the onset of one or more of its complications, such as neuritis, infection and cataract. The third, or "casual" group, comprising 47 per cent of the total, is made up of those who, with diabetes unsuspected, are found to be glycosuric on an examination conducted for a purpose unrelated to any suspicion of diabetes. It is to make the public aware of the presence of this group and the means and importance of discovering the persons who compose it that Diabetes Week has been designated.

Certain facts further emphasize the desirability of early diagnosis in diabetes. The longer the condition goes undiscovered, the more severe is its course likely to be, and it is known that sugar may be present in the urine for several years before symptoms pertaining to the disease become evident. This fact also explains its apparent onset with complications in 19 per cent of Beaser's cases—the patients had had diabetes for some time but did not know it.

Single negative urinalyses, moreover, are unreliable for the exclusion of diabetes mellitus. Stated differently, in the words of the author, "Even a single slightly positive test obtained under routine conditions, even though overshadowed by one or more previous, simultaneous or succeeding negative tests, should be taken to mean diabetes unless a glucose tolerance test proves otherwise."

### INCREASE IN TUBERCULOSIS

THE New York Tuberculosis and Health Association has reported a sharp increase in the number of new cases of tuberculosis in that city. For the first nine months of 1948 the total increase has amounted to 12 per cent, with a 17 per cent increase in the borough of Manhattan. The 6433 new cases registered represent an increase of 660 over the same period in 1947.

This increase is viewed with some alarm, and a corresponding increase in the number of deaths is expected, 70 per cent of all new cases registered being usually in an advanced stage of the disease. The patients now hospitalized within New York City number 5485, or 11 per cent more than a year ago. Tuberculosis sanatoriums, far from continu-

ing with the anticipated lightening of their load, are experiencing increased pressure and overcrowding.

New York's death rate for the corresponding period of 1948 was 40.4 per 100,000 population as compared with a rate of 38.9 for 1947. This represents an increase of 4 per cent.

Boston, similarly, according to an unpublished report from the Boston Health Department, has had reported 604 new cases for the first nine months of 1947 and 694 for 1948, an increase of approximately 15 per cent. The death rate in Boston, however, is close to 65 per 100,000, although some improvement in the rate is expected for 1948. The death rate for the country as a whole is well under 40.

### MASSACHUSETTS MEDICAL SOCIETY MALPRACTICE INSURANCE POLICIES

At the present time the office of the Society is receiving many requests for information concerning malpractice insurance policies and for information regarding which company issuing such policies is approved by the Society.

For the protection of the members of the Society, I believe it is best to quote from the recommendations of the Committee to Survey Malpractice Insurance as published in the *New England Journal of Medicine*, issue of December 4, 1947, under "Proceedings of the Council," as follows: "That no one company be recommended exclusively at this time."

This recommendation was adopted by vote of the Council.

H. QUIMBY GALLUPE, M.D., *Secretary*

### ATTENDANCE AT COUNCIL AND COMMITTEE MEETINGS

All too frequently those in the offices of the Society who are responsible for the execution of its official actions are impressed with the lack of information on important issues, and even opposition, to acts of the Society, on the part of fellows who have failed to acquaint themselves with the matters involved.

A more careful reading of the issues of the *New England Journal of Medicine* that pertain to Society activities, and better attendance at meetings of the Council and committees would go a long way toward clearing up these difficulties.

In order that the business of the Society may receive due attention, the Secretary will notify all district secretaries of the attendance at meetings of the Council and of those committees whose members are elected by the districts.

H. QUIMBY GALLUPE, M.D., *Secretary*

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### NEW TYPHOID-VACCINE DOSAGE

The time-honored dosage of typhoid vaccine of three doses of 0.5 cc, 1.0 cc and 1.0 cc given at intervals of seven to ten days is now to be abandoned. For many years it has been suspected that larger amounts of some biologic preparations were being given than were really required. Everyone has been reluctant, however, to reduce doses without good scientific basis, for fear that a decrease in protection would result.

The United States Army Medical Corps has pioneered in the studies regarding typhoid vaccine. Just prior to the war important improvements were made in the production and testing of the vaccine, based on a large volume of research carried out at the Army Medical Center.

Using this vaccine of uniformly high quality, the Army has determined that a smaller dosage schedule is possible. Hereafter the routine will be three 0.5-cc doses administered at intervals of seven to twenty-eight days. The Biologics Control Laboratory of the National Institute of Health has now approved this dosage, and has authorized manufacturers to make this change in the directions accompanying the packages. The Massachusetts Department of Public Health has recommended this dosage as an optional alternative since February, 1948. In line with the policy of the National Institute of Health, it is now recommended that the new dosage schedule be universally adopted. This change may be made with assurance that the immunity produced will be as good as is required. Repeated studies at the Division of Biologic Laboratories have shown that the vaccine made there is equal or superior in potency to all batches obtained to date from other laboratories for comparison.

The recommendations for revaccination have not been changed. Either a subcutaneous dose of 0.5 cc, or an intracutaneous dose of 0.1 cc, given annually, will maintain a satisfactory level of immunity.

## MISCELLANY

### YALE CHILD STUDY CENTER

The appointment of Dr. Milton J. E. Senn as director of the new Yale Child Study Center has been announced by President Charles Seymour. The new center, embracing all the specialties and social sciences that bear on pediatrics, will include also the famous Yale Clinic of Child Development, established by Dr. Arnold Gesell, who retired as professor of child hygiene on July 1.

Dr. Senn, a native of Wisconsin, is retiring from the position of director of the Institute of Child Development and professor of pediatrics in psychiatry at Cornell University Medical College to assume his new post, which will carry with it the Sterling Professorship of Pediatrics and Psychiatry.

### ANNUAL MEETING OF THE SILVER HILL FOUNDATION MEDICAL COUNCIL

The medical council of the Silver Hill Foundation held its annual meeting in New Canaan, Connecticut, October 15 to

17. The members, chosen to serve in an advisory capacity for a period of two years, met first in a scientific session led by Dr. William B. Terhune, medical director of the Foundation. After this meeting, the members and their wives and guests were entertained at the Country Club of New Canaan.

The Silver Hill Foundation is a psychotherapeutic unit devoted to the study, care and treatment of the psychoneuroses where patients are given brief, intensive psychotherapeutic and physiologic aid to re-establish their lives and their ability to work. The medical staff is composed of internists who, although they are diplomates of the American Board of Psychiatry and Neurology, are interested in the eclectic approach to the treatment of the psychoneuroses rather than adhering to any one formal school of psychiatry. The subject for discussion of the Council this year was "What Is the Ideal Method of Treating the Psychoneuroses, Psychosomatic Illnesses and Psychosocial Disorders?" Speakers were Dr. Harold L. Amoss, Dr. Arlie V. Bock, Dr. Walter O. Klingman, Dr. F. C. Redlich and Dr. Edwin G. Zahriskie.

### ADVISORY COMMITTEE TO CHILDREN'S BUREAU

The United States Children's Bureau, now a unit in the Social Security Administration of the Federal Security Agency, has organized an advisory committee to aid in the development of its programs for maternal and child health and crippled children's services. The Bureau is responsible for administering the \$18,500,000 in grants that Congress makes available each year to the states to extend and improve these services.

The committee of forty-seven advisers, appointed by the chief of the Bureau for a three-year term, includes the following New England members: Harriett M. Bartlett, associate professor of social economy, School of Social Work, Simmons College; Dr. Allan M. Butler, professor of pediatrics at the Harvard Medical School; Dr. William T. Green, head of the Department of Orthopedic Surgery of the Children's Hospital, Boston, Massachusetts, representing the American Academy of Orthopedic Surgery; Dr. James R. Miller, of Hartford, Connecticut, trustee of the American Medical Association, representing the Association and Dr. Duncan E. Reid, professor of obstetrics at the Harvard Medical School.

## CORRESPONDENCE

### DIABETES DETECTION DRIVE

*To the Editor:* Will you kindly publish the following open letter to the Physicians of America?

The finding of the million cases of unknown diabetes in this country poses a direct challenge to the American doctor. It is within his power to accomplish this feat. The existence of these cases in the United States has been demonstrated through a series of surveys, the most recent one conducted by the United States Public Health Service. The results of these studies now provide a springboard for organized medicine and a golden opportunity for physicians to seize the initiative on their own in this significant phase of public health.

The American Diabetes Association has planned a campaign to promote the early discovery and prompt treatment of the million undiscovered cases of diabetes. This campaign is unique in professional service, for according to plan the physician himself will be at the helm. Therefore, the plan cannot be prosecuted, or even started, without the endorsement and support of the entire medical profession through its governing bodies, national, state, county and local medical societies.

The plan proposed by the Association is simple, direct and sure. Through local diabetes associations, related to the American Diabetes Association and with the cooperation of local, county and state medical societies over the United States and Canada, it is planned to carry out blood-sugar screening tests by a new five-minute micro-blood-sugar method with simultaneous urinalysis for sugar with attention to the time in relation to the preceding meal. The procedure can be carried out apart from a formal laboratory. The only provision will be that the candidate must name a physician or clinic to which the results of the tests will be mailed for interpretation.

to the patient. *Under no condition* will a report be sent directly to the examinee. The effort is to bring the patient with unknown diabetes under his own physician's care. There will be no statistics and no red tape.

Simultaneously, the American Diabetes Association will carry on an intensive educational campaign directed first toward doctors' postgraduate courses. It will be directed toward the layman by radio, newspapers and other publicity channels in addition to the *A D A Forecast*, the Association's bi-monthly magazine, which brings to the diabetic patient homespun articles on the disease by eminent authorities in the field. At the same time the Association will place in the hands of physicians over the country an authentic *Handbook of Therapy*. Containing the most up-to-date information available, the *Handbook* will assist the physician in treating diabetic patients.

The week of December 6-12, immediately following the interim meeting of the American Medical Association, will be proclaimed as "Diabetes Week." This will be the formal beginning, the kick-off, of the Association's Diabetes Detection Drive. From this start, the program will continue on a long-term basis.

The Association is determined to do its part in finding these million diabetic patients and guiding them to you, their physicians, for treatment. May we count on your support when the matter comes up before your county or local medical society? The success or failure of the Diabetes Detection Drive depends upon you. You stand at the helm, this is *your* project.

HOWARD F. ROOT, M.D., *Chairman*

American Diabetes Association, Inc.

## MEDICINE IN POLAND (1948)

*To the Editor* Assigned to the American Embassy in Warsaw, Poland, on January 2, 1948, as attending surgeon, I had the opportunity of observing and working with Polish doctors for six months. It was necessary for the welfare of the people under my care that I become familiar with the intricacies of the hospitals in Warsaw, that I meet physicians from the different specialties, and that with our own facilities and theirs appreciated a scheme of medical treatment be worked out. My job was a pleasure, and I have many fond memories of time spent with Polish colleagues. It was an academic revelation to visualize their medical setup.

Formal comparison of American and Polish medicine is without real significance. It is of value that the physicians of an international United States of America know the level of medical education, medical care and the type of scientific endeavor in Poland. Understanding can help our outgoing aesculapiads and organizations better to deliver supplies, lecture tours and fellowships, as well as to evaluate better any Polish physician who might manage to leave Poland to apply for licensure in the United States of America. A recent bill before Congress to extend the G. I. Bill of Rights to allow servicemen to enroll in European medical schools makes it seem urgent that a spotlight be thrown on what really exists in these traditionally famous places of learning.

Poland is in general badly smashed after six years of struggle. It was smashed in such a way that its cultural and professional activities were made to suffer most. Eighty to 90 per cent of Warsaw was reduced to rubble—its hospitals, libraries and physicians barely survived the attack. In the Warsaw uprising of 1944 the medical facilities were smothered as 250,000 Poles died. Cracow, always the Polish Vienna, was luckier. Untouched physically, the manpower pipeline and scientific nourishment were cut off. Lodz, Poznan, Wroclaw, Gdynia and Lwow were all punished to some degree—perhaps Warsaw represents a rather high average picture of where medicine stands in Poland today.

In the year following the Allied victory UNRRA gave Warsaw a running start with equipment basic and for daily expenditure. Shortly thereafter the World Health Organization set up its offices and meted out fellowships to Poles eager to sail west across the Atlantic. Many were given the opportunity to go to England, Sweden and Switzerland in like manner, and WHO, together with the Unitarian Committee, sponsored visits from world-renowned specialists, who worked hard on arrival to cover the missing years of scientific improvement. Even now, 15 physicians from England, Sweden, Czechoslovakia and America are touring Poland representing the Unitarian Committee, and their success

so far has been extremely gratifying. Dozens of voluntary philanthropic organizations, such as Brethren Service, Catholic Welfare and the Quaker Mission, continue to advance supplies to Poland's barren armamentarium. The seemingly insurmountable barriers to accomplishment of these missions—finance, customs and politics—were and are being overcome slowly. In like manner is the westward approach to science displacing the old Vienna school of thought and practice.

Against this background one can look out on the field of medicine in Poland, but like the sailor in *Gulliver's Travels*, one must consider whether he is amongst the Lilliputians or Brobdingnagians. It takes time to adjust the sights. It is not merely a question of evaluating the various specialties of medicine. An appraisal of their integration, so vital in American science, must be carried out in detail to arrive at an understanding of where the healing art stands in this land, the battleground between the West and Eurasia.

Unlike Germany, at one time medically self-sufficient, Poland, perhaps since the days of Copernicus, Von Mikulicz and Rydiger, has relied on the importation of science. Thus, most of the men I learned to know and work with spoke either English or German, and often many other foreign tongues. As importers and followers they seldom seem to have excelled. Where greatness existed in a few, schools apparently failed to develop or to foster progress. Under constant duress Polish medicine, along with Poland, failed to gain speed. Facilities remained limited, and ambition to renovate was stifled by traditional professionalism. The backbone of Polish medicine, hardly sturdy before the war, was scourged by an invader nation, which overtly attempted to reduce the rank of this profession, among others of the noblest elements of Poland.

I was carried into the realm of Polish surgery at the Child Jesus Hospital (First Surgical Clinic of Warsaw University) under the direction of Professor Tadeusz Butkiewicz. I was able to work two or three mornings a week in the operating room and to engage in the ward rounds and in some of the conferences. I saw 100 general surgical beds handled by eight or more assistants (men or women averaging thirty or more years of age), most of whom had at least one other job that consumed afternoons and evenings and made their work at the clinic, for a nominal sum, merely a small part of their day. Students were taught on the run and entered into the scheme of things only superficially. Teaching and academic pursuits were borne, when time permitted, by one or two. My friend Dr. Jan Nielubowicz slept little in his devotion to his role of major domo in this realm.

From this department I became acquainted with the roentgenologists and some of the internists and surgical specialists, such as Professor Grucha, a very well trained orthopedist. I found these other fields of medicine more properly tilled, although ancient devices continued to slip into recognized modern forms of therapy. Pneumonias were treated with penicillin and thoracic suction caps called "bankis," because "das alte recht" still clung like a scab to the back of men's minds. But over this lay the pall of no interdepartmental co-operation. I saw that each professor held sway in his realm, irreproachably right, seeking consultation only when a severely ill patient demanded assurance.

In every department of the hospital supplies were short. Much of what they had had been donated by UNRRA and other charitable organizations. Swedish, German and American equipment rounded out the few materials manufactured in Poland. It seemed that politics dictated amounts received from central-government purchases. Yet the wards were fairly tidy and clean, and nursing attendance was quite adequate. No great technical skill was needed in the handling of ward work because many modern devices were as yet lacking.

Results in surgery in this clinic were fair, but much was left undone owing to lack of technique, equipment and knowledge in preoperative and postoperative handling. Follow-up observation was inadequate, so that long-range errors un-revealed did not add to the standard of work. The anesthesia relied on was not only appalling, but in itself limiting. When endotracheal anesthesia was introduced by Dr. Olle Friberg of Stockholm, its application appeared like a rainbow after a dreary rain. There was every indication that, given opportunity, the Poles could come to the fore. There was something to be noted in their traditional professional integrity, which allowed a man to carry on with pride though hindered

from every angle and which allowed even the most trying operation to be performed with practical bravado.

With 500 to 600 beds available in the Child Jesus Hospital the services seldom seemed taxed, although on several occasions there was some overflow into the halls. It was never clear how much of Poland was covered by the 15 or so hospitals in Warsaw, but certainly in some special fields patients covered on clinics here from places 500 to 400 kilometers away, even from cities where medicine was in itself quite capable.

Infrequently, I had the opportunity of visiting other hospitals. At the Wolski Hospital, Professor Landau clearly demonstrated on his sparkling medical service that he had been practicing "western medicine" since 1928. Dr. Mantel in surgery had operating rooms under his surveillance that lacked nothing in equipment, and his reputation in thoracic surgery seemed well deserved.

The few private clinics in which I attended patients now and then did not smack of good medicine, with nursing service makeshift and surgery performed in ancient rooms with such assistance as the attending man might be able to summon if an emergency case appeared. Anesthesia was heartrending in any event. These, then, were the sites where underpaid professors and privileged assistants rounded out their salaries, not happy in their lot, but unable to lift up the scale, being on the pan constantly themselves.

Thus, it was apparent that, as in any other plan of life, varying levels were attained, and medicine and surgery at times even though hard pressed could in capable hands rise above drab surroundings.

When I was permitted to attend the second annual (second since the war) surgical congress in Cracow, April 5-8, 1948, the surgical perspective of this struggling land was revealed. Here 500 of Poland's surgeons gathered, avidly attending Dr. Nowicki's and Dr. Glazka's early morning operating stunts, after which they crammed into a small lecture hall in the well preserved Cracow city hospital for the presentation of papers. Although the orthopedic specialists were to meet separately in the following days, they attended, making the conglomeration complete, and as one of my friends complained as we strove to view the operative site early one morning, "Very few men who could wield a knife were absent."

And yet they seemed to have accomplished little after the heat of enthusiasm had waned. One and a half days were spent in uncritical hickering about treatment of wounds, centering on the role of the sulfonamides and other chemotherapeutic agents. The remainder of the second day lingered on while the surgical treatment of tuberculosis, with endless discussions on the types of operations giving best results in putting the lung at rest, was proffered. Then the mad scramble of the last day, when a rush of unrelated, crowded-out topics appeared, with the scheduled aspirants hoping to find time for their literary work. A few interesting cases were presented, but by and large the series were small with little follow-up observation. Issues were raised that had been better discussed with evidence measured in other lands, as in some instances on spur-of-the-moment investigation. None of the papers bore the earmarks of intensive investigative work. There were no papers on medical-education or surgical-training plans. I was consoled when it became obvious that my friends were no less weary of the haranguing and no less disappointed, although "it was better than the last meeting." They were anxious to learn how a similar surgical congress was handled in America.

I had the opportunity of meeting Duzend Chorobski at this congress, and on my return to Warsaw began to visit his neurosurgical clinic in the Praga portion of town east of the Vistula river. Vigorous and esteemed, having studied and worked in many centers in Europe and in Montreal and Chicago, he demonstrated how much a well trained man could do even in difficult surroundings. Besides turning out much good surgery, Jerzy Chorobski had created a school of neurosurgery amidst ruins and already had two disciples abroad, one in Lodz and another in Cracow. He was constantly buoyed up by the generous gifts of American neurologists — buoyed up spiritually as well as supplied with the physical goods needed to run his service.

In these various clinics mentioned medical students needed some lucky enough to be allowed to do practical things in most instances spending much of their time looking in on rounds in surgery they never approached a sterile field. They complained bitterly, and their few friendly teach-

ers bemoaned the large numbers in general and the expanding female representatives. Their preclinic years were ordinary — once out in the clinic they matured under the existing plan of advancement only after six to eight years. After graduating most of the class turned toward the smaller provincial hospitals for training, where they became eligible after two years to write a thesis for their Polish M.D. A few tough enough to endure obscurity for some years in Warsaw's larger clinics entered into these more academic pursuits.

Lack of reading facilities and medical literature rounded out the difficulties of education, even a master of library technique was often halled in his attempt to hunt up poorly catalogued literature, much missing in confusion and in fact. All libraries closed at eight in the evening, with little help to keep them running.

And where, after all these things were measured, did the Polish patient stand? Theoretically, Poland has a highly developed system of health centers with special setups for tuberculosis control and venereal-disease treatment — much of this exists on paper only. The average worker to enjoy medical care pays 15 to 25 per cent of his earned wage. The peasants, theoretically covered by insurance, were pretty much on their own, and many had to save up for months to pay for treatment of a medical ailment that in the meantime ran its course. They spent many earning hours waiting for care in understaffed clinics. The underpaid physicians, obliged to care for those registered, tended to give better attention to those well off, not covered by an insurance plan, who were willing to pay a reasonable fee. Even in a hospital patients were faced with the frequent necessity of obtaining their own medication on the "open market." Home-cooked food littered the wards to supplement the hospital's meager diets. Dentists, well thought of by most Americans seeking their aid, were overworked and charged a great deal, so that teeth examined in the workers were in the majority either naturally good or from neglect carious. The Poles attending our American hospital in Warsaw seemed amazed at our cleanliness, our armamentarium of drugs and our new equipment.

While I was in Poland, I saw the Unitarian Hospital in Piekary, near industrial Katowice, grow up. I heard of plans to start a large medical center in Lodz. I saw medical students being turned out to ease the burden being borne by 6000 doctors caring for 24,000,000 Poles. I heard of continued efforts to create a system of health centers centrally supported. But above all I had a chance to talk to many young doctors who saw the failure of their old professional system and saw the need for fundamental research, as well as for better medical education and libraries, and these men realized that the West points the way to better medicine. At times they saw that old German dictums and much of Germany's arbitrary medical contributions and outmoded methods had not only led to the downfall of German medicine but also had lagged in progress while a new system of science with perhaps some humanism had grown up to the north and west.

It was all too clear that although daily changes seem to affect the practicing doctors little, their involvement in the catastrophic decline of the nation was complete — he it aggressor or aggrieved. Although Poland demanded consolation by its very plight, it demonstrated how there can prevail a communion of aesculapiads that should be fostered and nourished and looked to for the establishment of world health and peace.

## BOOK REVIEW

*Telepathy and Medical Psychology*. By Jan Ehrenwald, M.D. With a foreword by Gardner Murphy. 8<sup>vo</sup>, cloth, 212 pp. New York: W. W. Norton and Company, Incorporated, 1948. \$3.00.

This book is composed essentially of two parts: presentation of proof that telepathy exists as a phenomenon distinct from other psychic processes, and a presentation of the thesis that telepathy is in part or whole the basis of psychopathology.

To prove the first assumption, statistical data and material from case studies are presented in an attempt to put the study

on a scientific basis. In considering statistics, one must remember that they do not by themselves prove a thesis. For a thesis to become a science, two factors must be present: one must be able to predict behavior or performance from the acquired data, and the laws presented must apply to all cases that fall within the limits set up by the thesis. In no way does telepathy fill these requirements since one cannot predict its performance, and there is no explanation of the mechanism of how it works.

Psychiatry in general has fallen into the error of attempting to present itself as more nearly a science by making comparisons with well established scientific, usually physical or chemical, laws. This hook at times does the same thing. One must remember, under these circumstances, that comparisons are only assertions of belief and that comparison in, and of itself, proves nothing and does not make so subjective a field as psychiatry any more scientific than if it were not made.

The second thesis is not documented with a sufficient number of cases. Certainly, in a phenomenon so subjective as the products of mental and emotional functions of the central nervous system, wherein even hallucinations appear to be real, the occasional occurrence of the same thought at the same time to two or more people can be proof of little more than chance. The fact that patients produce material similar to the thoughts of the analyst is not to be wondered at, and has been discussed in numerous books and papers and need not be detailed here. One can only use it to support a belief in telepathy if one believes in telepathy as the dynamic principle. To say that distortion of personality leading to psychoses and neuroses or other functional disturbances is based on telepathic transference of thoughts and feelings is but begging the point. One still has not explained why one person reacts to such influences, if there is such a reaction, and another does not.

The explanation advanced is far too simple. The continuing stimuli from one's environment and from within one's self are so numerous and so varied that personality is always the complex of millions of interlacing threads. One can scarcely ever hope to find the basis of personality disorders in one general underlying principle.

Finally, after the book has been read, an attempt at objective evaluation suggests that little has been added in the way of proof of existence. One still must believe or not according to one's personal bias. As each new section is begun the reader hopes that he is going to have meat to chew on, but at the end of the section there is little more substance than a mouthful of spun candy hought at a fair

## NOTICES

### ANNOUNCEMENT

Dr. Morris Courtiss announces the removal of his office to 314 Commonwealth Avenue, Boston.

Dr. Manuel Kaufman announces the removal of his office from 419 Commonwealth Avenue to 1093 Beacon Street, Brookline, for the practice of internal medicine.

### NORFOLK DISTRICT MEDICAL SOCIETY

A meeting of the Norfolk District Medical Society will be held at the Hotel Kenmore, Boston, on November 23, at 8 p.m.

The program will consist of a "Legislative Meeting," at which members will meet incumbent and recently elected members of the State Legislature.

Physicians and members of the Women's Auxiliary of the Norfolk District Medical Society are invited.

### NEW ENGLAND DERMATOLOGICAL SOCIETY

A regular meeting of the New England Dermatological Society will be held at the Boston City Hospital, Skin Out-Patient Department, at 2:00 p.m. on December 1.

These meetings are open to members and invited guests only.

### INTERNATIONAL CONGRESS ON RHEUMATIC DISEASES

The seventh International Congress on Rheumatic Diseases and the first to be held in the United States will take place

at the Waldorf Astoria in New York City, May 30 to June 3, 1949, inclusive. This congress is sponsored by the International League against Rheumatism. The host is the American Rheumatism Association in co-operation with the New York Rheumatism Association.

Seven scientific sessions are planned, and five one-hour round-table conferences on various clinical topics will be held under the leadership of authorities in the respective fields. Short clinics, papers and reports will be given concurrently at four or five New York hospitals during three afternoons. Evening entertainment will be provided. The registration fee is \$10.00.

Members of the International, the European, and the Pan American Leagues against Rheumatism as well as the Canadian Rheumatism Association, British Empire Rheumatism Council, the Heberden Society of London, and the ten state or city Rheumatism Societies affiliated with the American Rheumatism Association are especially invited.

## SOCIETY MEETINGS AND CONFERENCES

### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, NOVEMBER 25

#### FRIDAY, NOVEMBER 26

- \*9:00 a.m.-12:00 p.m. Combined Medical and Surgical Staff Rounds Peter Bent Brigham Hospital
- \*12:00 p.m. Clinical Conference on Urology Margaret Jewett Hall, Mt. Auburn Hospital, Cambridge

#### MONDAY, NOVEMBER 29

- \*12:15-1:15 p.m. Clinicopathological Conference Main Amphitheater Peter Bent Brigham Hospital
- 5:15 p.m. Staff Meeting Harris Hall New England Deaconess Hospital

#### TUESDAY, NOVEMBER 30

- \*12:15-1:15 p.m. Clinicorontogenological Conference Peter Bent Brigham Hospital
- \*1:30-2:30 p.m. Pediatric Rounds Burnham Memorial Hospital for Children Massachusetts General Hospital

#### WEDNESDAY, DECEMBER 1

- \*11:00 a.m.-12:00 p.m. Medical Rounds Amphitheater Children's Hospital
- \*12:00 p.m.-1:00 p.m. Clinicopathological Conference (Children's Hospital) Amphitheater Peter Bent Brigham Hospital
- 2:00 p.m. New England Dermatological Society Skin Out Patient Department, Boston City Hospital
- \*2:00-3:00 p.m. Combined Clinic by the Medical, Surgical and Orthopedic Services Amphitheater Children's Hospital

FOURTH ANNUAL SERIES OF INTENSIVE  
POSTGRADUATE COURSES

1	Ocular Pathology Motility and Orthoptics	January 10-14 1949
2	Psychosurgery	January 24-28 1949
3	Psychiatry	January 31-February 11 1949
4	Therapeutics	January 31-February 4 1949
5	Gastrointestinal Problems in Pediatrics	February 7-11 1949
6	Obstetrics	February 14-18 1949
7	Gynecology	February 21-25 1949
8	Anesthesiology	February 28-March 4 1949
9	Surgical Physiology	March 7-11 1949
10	Abdominal Surgery	March 14-25 1949
11	Bone and Joint Surgery	March 28-April 1 1949
12	Neoplastic Diseases	April 4-8 1949
13	Metabolic Diseases	April 11-15 1949
14	Thoracic Diseases	April 18-22 1949
15	Cardiovascular Diseases	April 25-May 6 1949
16	Gastroenterology	May 9-13 1949

By appropriate combinations of the above the following  
longer courses can be arranged  
For the Psychiatrist (Courses No 2 3) January 24-February 11 1949  
For the General Physician (Courses No 4 5 6) January 31-February 18 1949  
For the Obstetrician (Courses No 6 7) February 14-25 1949  
For the Surgeon (Courses No 7 8 9 10 11 12) February 21-April 8 1949  
For the Internist (Courses No 13 14 15 16) April 11-May 13 1949  
Other combinations can also be arranged

A Distinguished Guest Faculty Will Supplement the Local Staff  
Registration in each course is limited

Hotel accommodations are available  
Veterans can use their benefits under the G. I. Bill

## Sam's Hens Wear Spectacles!

*Yes, it's a fact! Sam's brood of  
two dozen hens are wearing spectacles  
—which he bought from a mail-order  
house in Capitol City*

Sam says it works (and big poultry  
raisers say so, too) The hens see each  
other through soft colored glasses, and  
instead of fighting and picking at each  
other, they're placid, gain weight, and  
lay more eggs

*Makes me almost wish we could  
have rose-colored glasses for human  
beings, too So that instead of quarrel-  
ing and criticizing, like we generally  
do so much of the time, we'd simply  
live and let live in contentment*

From where I sit, the human race  
wastes a powerful lot of time in wran-  
gling over minor issues whether  
a man should drink beer or cider . .  
whether a woman should wear slacks  
or skirts instead of seeing each  
other through "spectacles" of toler-  
ance that enable us to live-and-let-live  
like Sam's brood of chickens

# SHOULD VITAMIN D BE GIVEN ONLY TO INFANTS?

**V**ITAMIN D has been so successful in preventing rickets during infancy that there has been little emphasis on continuing its use after the second year.

But now a careful histologic study has been made which reveals a startlingly high incidence of rickets in children 2 to 14 years old. Follis, Jackson, Eliot, and Park\* report that postmortem examination of 230 children of this age group showed the total prevalence of rickets to be 46.5%.

Rachitic changes were present as late as the fourteenth year, and the incidence was higher among children dying from acute disease than in those dying of chronic disease.

The authors conclude, "We doubt if slight degrees of rickets, such as we found in many of our children, interfere with health and development, but our studies as a whole afford reason to prolong administration of vitamin D to the age limit of our study, the fourteenth year, and especially indicate the necessity to suspect and to take the necessary measures to guard against rickets in sick children."

\*R H Follis, D Jackson, M M Eliot, and E A Park. Prevalence of rickets in children between two and fourteen years of age, Am J Dis Child 66 1-11, July 1943

MEAD'S Oleum Percomorphum With Other Fish-Liver Oils and Viosterol is a potent source of vitamins A and D, which is well taken by older children because it can be given in small dosage or capsule form. This ease of administration favors continued year-round use, including periods of illness.

MEAD'S Oleum Percomorphum furnishes 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10- and 50-cc bottles and bottles of 50 and 250 capsules. Ethically marketed.

## THE SURGICAL TREATMENT OF MITRAL STENOSIS\*

### I Valvuloplasty

DWIGHT E. HARKEN, M.D.,† LAURENCE B. ELLIS, M.D.,‡ PAUL F. WARE, M.D.,§  
AND LEONA R. NORMAN, M.D.¶

BOSTON

NEARLY fifty years ago the possibility of relieving the obstruction to blood flow through a narrowed mitral valve was first suggested. Subsequent attempts have been made to accomplish this.<sup>1-16</sup> The surgical technics employed in these bold but disappointing adventures have been variously described as valvulotomy and valvulectomy. Much of the discussion of the theoretical value of this procedure has been concerned with the problem whether the patient would tolerate a surgically induced mitral insufficiency better than his existing stenosis. This, however, is an oversimplification of the situation. Many factors produce the symptoms and determine the course of the disease in patients with mitral stenosis. Among these are not only the degree of obstruction and of insufficiency of this valve but also the tendency to tachycardia or arrhythmia and the ease of its control, associated valvular defects, the activity of rheumatic disease, the damage to the myocardium of the two ventricles and alterations, functional or organic, in the pulmonary vascular circuit. Clearly, the problem of surgery in mitral stenosis is not simply that of breaking down a barrier to the flow of blood through a stenotic orifice.

At the present time, there are technics for studying cardiopulmonary dynamics that are vastly more extensive and more accurate than those available

to earlier students of this problem. They provide objective data for the evaluation of the patient before operation and the assessment of the result of surgery. In our opinion, the undertaking of surgery of such an experimental and hazardous nature in a complex physiologic situation without complete, objective studies is entirely unjustified.

It is the purpose of this first report to set forth certain preliminary impressions concerning the selection of patients for operation, the nature of the operation of choice and the surgical handling of the patient. In particular, a technic of direct valvuloplasty for mitral stenosis is presented.

### SELECTION OF PATIENTS AND CHOICE OF OPERATION

In brief, patients selected for operation should give unequivocal signs of mitral stenosis, should not have any significant degree of involvement of other valves or any other type of cardiovascular disease and should not present evidence of active rheumatic carditis or bacterial endocarditis. They should not have associated disease in itself incapacitating, but should have cardiac symptoms that are disabling and intractable to medical therapy. These patients suffer from profound pulmonary symptoms in various combinations, not only dyspnea, on exertion and at rest, and orthopnea, but also paroxysmal dyspnea, pulmonary edema, hemoptysis and chest pain. They may or may not have right-sided heart failure with peripheral venous congestion, hepatomegaly and peripheral edema.

Certain basic factors involved in the physiologic state of the circulation in mitral stenosis must be considered in selecting patients for operation and in choosing the surgical procedure most likely to be beneficial. These are the ability to maintain an adequate resting cardiac output and to increase it on exertion, the basic cardiac rhythm and the resting heart rate, the change on exertion, emotion and so forth, and the degree to which tachycardia can be controlled by medical means, the ex-

tent of elevation in pressure in the left auricle and pulmonary veins at rest, during exercise and tachycardia, and the relative importance of mitral regurgitation in the increase in this pressure, the degree of right ventricular failure, and the problem of organic disease in the pulmonary circulation. Since the patients who are under discussion had clinical signs of endocarditis confined to the mitral valve alone and no evidence of active myocarditis, neither the effects of disease involving other valves nor the possibility of left ventricular failure need be considered.

With these factors in mind, a preliminary classification of patients into three groups has been made.

#### *Group A*

This group includes patients with a low resting cardiac output, which is unchanged or even decreased on exercise, and with an elevated pulmonary-artery pressure. Signs of right ventricular failure may appear in addition to the pulmonary symptoms. For such patients, the operation of "valvuloplasty" may be helpful since the available evidence indicates that mitral obstruction is of major importance in their clinical condition.

#### *Group B*

In this group are patients whose resting cardiac output is within normal limits and usually increases with exercise. In spite of the adequate cardiac output, they often have as severe pulmonary symptoms as those in Group A, and the pulmonary-artery pressure is also elevated. The pathophysiologic mechanism in these cases may be a predominance of mitral regurgitation over the element of stenosis, or it may be that a high left auricular pressure maintains flow through narrowed mitral orifices to an adequate level. Secondary organic pulmonary vascular changes may also occur as an important element in producing the pulmonary symptoms. These patients may be benefited by the production of an artificial interatrial septal defect, which will decompress the left auricle and the pulmonary venous hypertension, especially at high peaks during periods of strain. This operation is probably not suitable for patients who have had right ventricular failure because of the added burden produced in the right ventricle by the recirculation of blood through this chamber and the pulmonary circuit. Such an operation may be contraindicated for patients in Group A, in whom too great a proportion of blood may be diverted through the shunt, and with decreased left atrial pressure, blood flow through the stenotic mitral orifice would be reduced still further to a level incompatible with life.

#### *Group C*

This category includes patients whose incapacitating symptoms, particularly attacks of pulmonary edema, are associated with rapid heart action that cannot be controlled by medical measures. The cardiac output may be normal or low, and the pulmonary-artery pressure elevated, the patients are not deemed suitable candidates for either of the operations mentioned above because of the extent and severity of their disease. The occasional patient with mitral stenosis who has attacks of severe chest pain, especially "hypercyanotic angina," may also fall into this group.<sup>17</sup> For these patients, a palliative procedure may be the removal of the cardiac sympathetic accelerator and afferent nerves. In 2 successive operations, the inferior cervical ganglion and the first four or five dorsal sympathetic ganglions are removed from each side through a small cervical incision. The relief afforded is through the production of a slower heart rate or the interruption of pain fibers. It is also possible that some additional direct effect on the pulmonary circulation is produced. A patient on whom such a denervation was performed has had dramatic relief from attacks of pulmonary edema for eleven months.

It is likely that the eventual surgical management of mitral stenosis will include combinations of these three operations. At the present time, however, it seems safest for the patient and consistent with the clearest understanding of the potentialities of each operation to carry them out singly. Again, it should be emphasized that the evaluation of the indications for these operative procedures and of their results should be kept on an objective basis, all the investigative tools that are available being used.

We have now treated 5 patients with mitral stenosis surgically. Two of these patients have had valvuloplasty, 2 have had atrial septal defects created, and 1 has had cardiac denervation. There has been 1 death, this was the first patient on whom a valvuloplasty was performed. This case is reported in detail below. It was from our experience in this operation that we came to appreciate the devastating effects of tachycardia in the presence of mitral stenosis and regurgitation. All the other patients are living and have had subjective improvement of their symptoms. Preliminary follow-up studies in 2 cases indicate that the objective improvement is considerably less striking than the subjective benefit.

#### SURGERY OF MITRAL STENOSIS IN THE PAST

During the latter part of the nineteenth century, the physiology of the circulation and of artificially produced valvular defects was the focus of some attention. The progress made in these studies culminated in the suggestion by Brunton<sup>1</sup> in 1902 that stenosis of the mitral valve might be relieved

surgically. Experimental support of this thesis came from the work of Haecker,<sup>2</sup> Bernheim,<sup>3</sup> and Cushing and Branch.<sup>4</sup> Surgical technic was studied by Schepelmann,<sup>5</sup> and later by Carrel and Tuffier.<sup>6</sup> During the decade from 1920 to 1930, clinical trial of mitral-valve surgery was made.

The most extensive experience was that of Cutler, Levine and Beck,<sup>7-12</sup> who operated on 7 patients of whom only the first survived. Cutler and his group attempted incision of the valve with a tenotomy knife in their first 3 operations. Further consideration of the thick, tough, calcareous valves made it obvious that incisions in the stenotic funnel were probably impossible and certainly inadequate. A cardiovalvulotome utilizing the principle of counterpressure was developed. Unfortunately, none of the patients on whom this instrument was used survived. Allen and Graham,<sup>13-14</sup> Souttar<sup>15</sup> and Pribram<sup>16</sup> reported 1 case each. Of these, only Souttar's patient survived, however, he had but "dilated" the mitral ring with his finger, whereas the others had attempted incision by cardiovalvulotome.

Instruments for direct visualization and manipulation within the heart have been used in cardiac

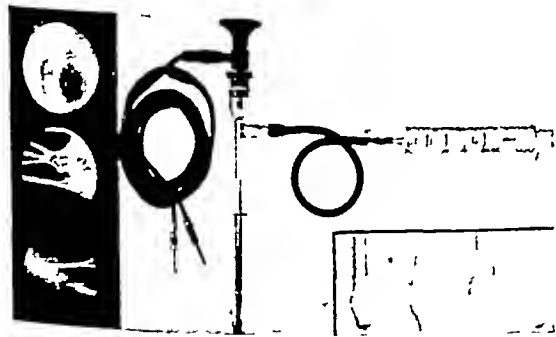

FIGURE 1 Assembled Cardioscope, with Sketches of a Pulmonary Vein, Mitral-Leaflet Edge and Papillary Muscle, as Seen through the Instrument

operations.<sup>13-18</sup> (Fig 1), but it is our opinion that the limited vision afforded by them does not warrant the increased operative hazard. To be sure, the ultimate technic in intracardiac surgery will embrace good endoscopic visualization or the utilization of a temporary mechanical substitute for the heart and lungs, allowing direct open operation on the interior of the heart during the period of suspended function.

## BASIC PRINCIPLES AND TECHNIC OF VALVULOPLASTY

The efforts of Cutler and Beck at correcting mitral stenosis formed the basis of our interest in this field. Discussion of the subject with Dr. Cutler before his death made it possible to correlate his experience with our own in cardiac manipulation. The rationale for valvuloplasty was predicated on this experience<sup>19-23</sup> and extended as the result of our first and only fatal operation.

In their operations, Cutler and Beck<sup>11</sup> employed a technic in which the heart was rotated forward and outward from the position of optimum function (Fig 2). One of us (D. E. H.) had found in

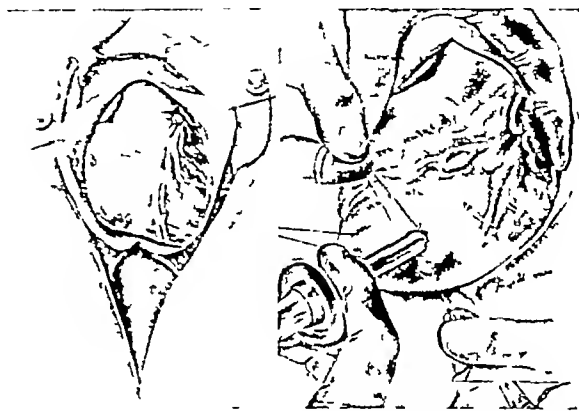

FIGURE 2 Illustrations Demonstrating the Exposure of the Heart and the Dislocation of the Heart from the Position of Optimum Function to Introduce the Valvulotome through the Ventricle. (Reproduced from Cutler and Beck,<sup>11</sup> by permission of the publishers.)

operating on hearts of otherwise robust American soldiers in the course of removing foreign bodies that this very sort of dislocation was invariably associated with violent disorders of rate, rhythm and output. These have been discussed in a previous publication<sup>21</sup> and documented in a motion-picture film in color.<sup>24</sup> If healthy hearts could not tolerate this dislocation, it is hardly likely that hearts damaged by rheumatism associated with far advanced mitral stenosis would fare better, much less tolerate the added insult of insertion of the valvulotome through the left ventricle. Indeed, it seems likely that a high mortality might result in these patients from dislocation of the heart alone, without any intracardiac manipulation.

The first principle is as follows: *the operation should be performed without dislocation of the heart from the position of optimum function.*

Again with the work of Cutler and Beck in mind, it was evident that it was most difficult to strike the apex of the stenotic funnel satisfactorily from

its ventricular aspect (Fig. 3). However, any instrument introduced from the auricular side tends to find the fish-mouthed opening with great ease. The objection to using the auricular appendage had been that it was often too thin and dilated to permit safe surgical entrance. It has been our experience that it is not often too thin for such an approach, if such a situation were encountered, the left superior pulmonary vein or a branch thereof could be used as a port of entry (Fig. 4).

The second principle is as follows: *the button-hole opening of the stenotic mitral valve should be approached from the auricular side so that the funnel directs the cutting instrument to the leaflet margin.*

In spite of these attractive technics for approaching the mitral funnel from above without displacing the heart, there still remains the question that has haunted all discussions of this subject: Is it physiologically advantageous to convert tight mitral stenosis into free regurgitation? Clinicians have been arguing for forty-six years whether mitral regurgitation is better borne than stenosis or the reverse. It is apparent that complete stenosis is

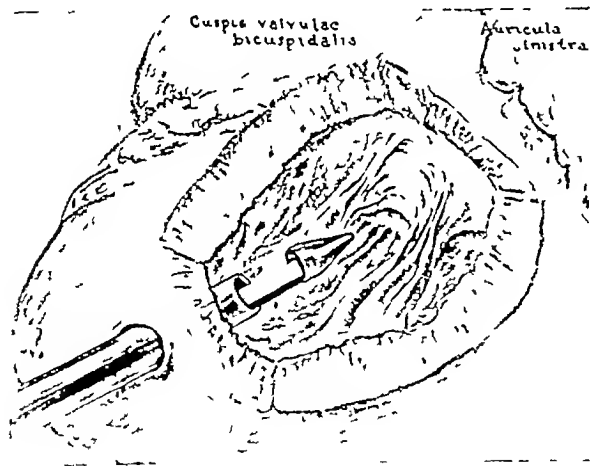

FIGURE 3 Diagrammatic Representation Suggesting Difficulty of Finding the Apex of the Stenotic Funnel Blindly. The dotted line indicates that the surgeons planned to remove a segment of the anterior mitral leaflet. (Reproduced from Cutler and Beck,<sup>11</sup> by permission of the publishers.)

incompatible with life. Conversely, complete regurgitation is promptly fatal to the experimental animal, and patients tolerate marked degrees of mitral insufficiency poorly. Thus, either stenosis or regurgitation in advanced stages can cause the patient's death. The questions before the surgeons are: Is there any compromise between too small an opening in stenosis and a slightly larger opening at the cost of more regurgitation? Is there any way to restore some valvular action to the damaged

valve? Are some types of insufficiency better borne than others? Ideally, surgical intervention should restore perfect valvular action, then the correction of obstruction in the light of the associated degree of insufficiency that is immediately produced would

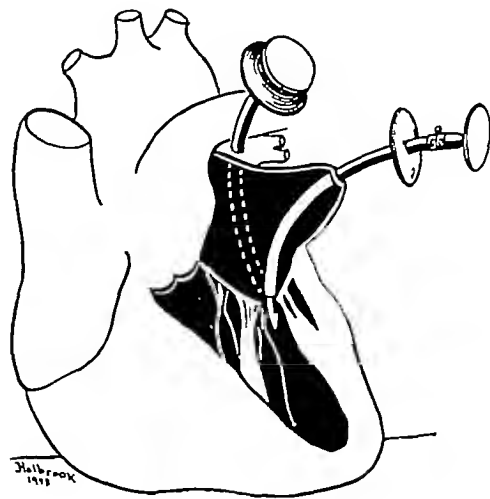

FIGURE 4 Cardiovalvulotome in Position after Insertion through the Left Auricular Appendage and the Alternate Approach through a Branch of the Pulmonary Vein (Dotted Line). The cutting edge is in the ventricle, directed toward the fused posterolateral commissure of the stenotic funnel.

not come under consideration. Unfortunately, that quality of valvuloplastic technic has not been attained.

During early work in our laboratory concerned with the experimental production of bacterial endocarditis,<sup>23</sup> the impression was gained that more than twice as many animals died from the destruction of the anterior mitral leaflet as from a corresponding destruction of the posterior leaflet. More recently, in 4 animals, it was found that left-auricular-pressure increments were roughly twice as high (equivalent to 10 to 20 as opposed to 5 to 10 cm. of saline solution) when anterior defects were produced as contrasted with posterior defects, and these changes were further increased during tachycardia. This suggested that insufficiency produced in various ways had different effects on the cardiac output and on the degree of regurgitation. Studies on a post-mortem human heart preparation supported the hypothesis that there was more regurgitation from an anterior than a posterior defect. These experiments seem interesting to us but are not yet sufficient to be regarded as conclusive. They only support a theory that can be presented diagrammatically.

In Figure 5 it is apparent that the anterior leaflet acts as a baffle that deflects blood toward the aorta,

whereas the posterior leaflet acts as an obstruction directly in the path of blood flow from the ventricle to the aorta. If the anterior leaflet is cut, the baffle or shunt to aortic output is compromised, and yet the obstruction of the posterior leaflet remains. Conversely, if the posterior leaflet is resected, the obstruction is removed, but the outflow through the aorta is less affected.

Direct palpation of the mitral leaflets throughout the cardiac cycle offers another type of informa-

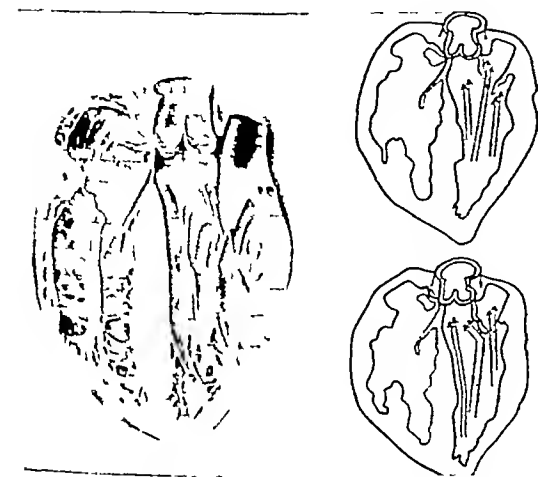

FIGURE 5 Cross-Section of Heart, Showing the Relation of the Mitral Leaflets to the Aortic-Outflow Tract  
The upper diagram illustrates the outflow tract broken by anterior valvulotomy, the posterior-leaflet obstruction remains. The lower diagram demonstrates the anterior leaflet intact as the wall of the outflow tract, the "selective insufficiency" being produced by removal of the posterior leaflet.

tion in this regard. When the exploring finger is introduced through the left auricular appendage of a dog, the anterior leaflet swings free throughout the cycle, but the posterior leaflet is squeezed and buttressed by the posterolateral wall of the left ventricle in systole. In diastole, the myocardium swings away from the normal veil-like posterior mitral leaflet. Again, it seems advantageous to remove segments from the posterior leaflet on its lateral margins in the stenotic funnel, such defects may correct obstruction during diastole (auriculo-ventricular flow) and yet may be occluded by the contracting, buttressing myocardium during systole, allowing less regurgitation (ventriculoauricular flow) than a surgical defect in the anterior mitral leaflet. Thus, some degree of insufficiency having been accepted as unavoidable after surgical enlargement of the mitral orifice, the theory of "selective insufficiency" was evolved as being the most likely to benefit selected patients. Such insufficiency was produced in the first patient operated on. At the present time, the posterior defects and selective

insufficiency are so created that the two commissures are cut away by wedge-shaped resections, with a view toward restoring some valvular action to the distorted, thickened leaflets. The wedge resections attempt to remove the fused zone that immobilizes the leaflets. This is the simplest form of "valvuloplasty" (Fig 6).

The third principle is as follows: *surgical enlargement of the stenotic orifice should be so planned that there is minimal burden from the associated regurgitation (selected insufficiency) and maximum restoration of valvular function (valvuloplasty).*

Our experience with the first patient on whom operation was performed led to a fourth principle. The case history of this patient is as follows:

CASE 1 J. B., a 26-year-old tool grinder, was referred to the Boston City Hospital on March 12, 1947\*. The present illness dated from April, 1946, when for the first time, he coughed up small amounts of pink frothy sputum. Massive hemoptysis occurred in December, 1946, and recurred in February, 1947. Both episodes lasted for 10 days. The second episode was especially severe, producing shock and depleting the patient to half normal erythrocyte and hemoglobin levels. There was no dyspnea, orthopnea or chest pain.

The past history revealed frequent sore throats in childhood, but no definite history of rheumatic fever. The patient had been active and in good health and had passed a life-insurance examination in 1939 without difficulty. In 1942 he was told that he had rheumatic heart disease when he was rejected by the Selective Service board.

Physical examination revealed the maximal apical impulse 7.5 cm left of the midsternal line in the fifth interspace, the midclavicular line was at 8.5 cm. The mitral first sound was increased. There was a Grade II blowing systolic and a rumbling diastolic murmur, with presystolic

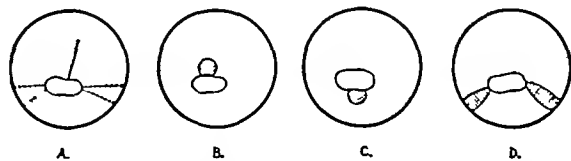

FIGURE 6 Diagrammatic Representation of Various Operations on the Stenotic Mitral Ring as Seen from Above  
A, anterior valvulotomy (dotted lines indicate zones in the solid stenotic funnel that were commissures in the predisease state). B, anterior-leaflet valvulotomy. C, posterior-leaflet valvulotomy. D, "selective insufficiency" and "valvuloplasty" by resection of the immobilizing commissure bridges.

accentuation. The lungs were clear to examination. There was no evidence of venous congestion, hepatomegaly, ascites or peripheral edema. The blood pressure was 118/70. Teleroentgenography showed slight increase of the hilar shadows, normal lung fields and a heart that was somewhat enlarged with a contour consistent with mitral stenosis. There was no evidence of pulmonary disease by bronchoscopy and bronchography. The electrocardiogram was consistent with right ventricular enlargement, and the broad, notched P waves were suggestive of auricular enlargement. The circulation time (arm to tongue) was 16 seconds (calcium gluconate). The venous pressure was equivalent to 95 mm of water. Examination of the blood disclosed a red-cell count

\*Referred by Dr. Sidney Solomon of Everett, Massachusetts.

of 3,850,000, and the hematocrit was 34 per cent. Catheterization of the right side of the heart showed an increased pulmonary-artery pressure of 55/30, with a mean pressure of 42. The right ventricular pressure was 50/7 (elevated). The resting cardiac output was within normal limits (5.95 liters per minute). A diagnosis of rheumatic heart disease with mitral stenosis, pulmonary hypertension and hemoptysis was made. It was decided to perform partial mitral valvulotomy on March 22.

Preoperative medication included 0.40 gm of nembutal, 150 mg of demerol and 0.65 mg of scopolamine. The patient received quinidine (0.4 gm) on the morning of operation. Immediately before induction with pentothal (2.5 per cent solution), 0.65 mg of atropine was given intravenously. Then curare, 30 units, was given and repeated in 10 minutes. An endotracheal tube was then inserted, and the balloon inflated. Shortly thereafter, ether was added slowly to the anesthetic mixture. Continuous electrocardiographic recordings were made throughout the procedure.

The operation was performed with the patient on his back, with the left side elevated 30°. The head of the table was also elevated 30°. The incision in the third intercostal space extended from the sternum to the left anterior axillary fold.

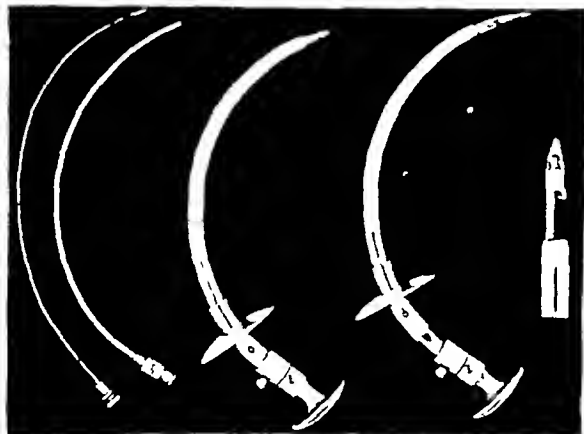

FIGURE 7 Photograph of the Cardiovalvulotome

On the left the trocar and cannula used in pressure determinations are illustrated. In the center the cardiovalvulotome in closed and open positions is shown. On the right, the detail of the cutting edge is demonstrated.

The pectoralis major and minor muscles were split. The mammary vessels were ligated and divided. The second and third costal cartilages were cut, the pleura incised, and the ribs spread. The thoracic inlet was infiltrated from within with 2 per cent procaine. The left superior pulmonary vein was isolated distally from the pericardium up to and including the anteromedial vein. Hemostatic traction sutures of No. 5 silk were looped around these veins. Transverse hemisection in the anteromedial vein between the control sutures allowed insertion of a No. 10 ureteral catheter into the left auricle. A mean pressure equivalent to 450 mm of water was recorded. The valvulotome (Fig. 7) was then inserted, and a segment was taken from the posterior leaflet of the mitral valve. The interauricular pressure was then recorded as equivalent to 470 mm of water. The valvulotome was reintroduced, and another disk removed from the posterior leaflet. Auricular pressure after this resection of the valve overflowed the 500-mm water manometer. The rise in left auricular pressure was completely incomprehensible at this time, and it was deemed unsafe to resect any more of the leaflet. The ureteral catheter was removed, and the vein was ligated. It was estimated that less than 100 cc of blood was lost in the five intracardiac manipulations. The chest was closed in layers with interrupted

sutures. During operation, the patient received 40 cc. of plasma, 150 cc of 5 per cent dextrose in water and 800 cc. of whole blood. His initial pulse was 78, but it rose to levels of 110 during induction of anesthesia. Shortly after the pleura had been opened and the ribs spread, the pulse gradually climbed to 140, remaining at this level throughout the remainder of the operative period, at all times it was regular. The blood pressure was constant at 100/60 to 110/70. Immediately after operation, the blood pressure was normal, the pulse 150 to 160, and the color fair. After the operation, the patient was observed on the operating table for 2 hours. The pulse remained unchanged, the systolic blood pressure gradually fell to 100. At this point, he was returned to the ward, where cyanosis of the nail beds and ears, with mottling of the forehead were noted. A positive-pressure mask was adjusted to provide 4 cm of expiratory resistance for 15 minutes of every hour.

The temperature gradually rose to 106.6°F 6 hours after operation, and at the same time, the systolic blood pressure dropped to 50. The clinical condition varied from minute to minute. Whole blood in small amounts was given to elevate the blood pressure, but signs of pulmonary congestion developed. The positive-pressure mask was poorly tolerated, and the resistance had to be eliminated. Rectal administration of aspirin and constant alcohol sponging reduced the temperature to 102.2°F, and it was maintained at this level. With the onset of hyperpyrexia, the patient became completely comatose, with a flaccid paralysis. There were no localizing signs. Eight hours after operation, intravenous metrazol was given with dramatic response, the patient became rational and conscious, talked fluently, moved all extremities and had normal reflexes. However, the systolic blood pressure never rose above 80, and cyanosis persisted. Shortly after the metrazol, the patient relapsed into unconsciousness, and the metrazol was repeated in 1-cc doses, intramuscularly, every hour thereafter, with temporary return of consciousness and activity. The patient continued to exhibit varying degrees of peripheral vascular collapse, pulmonary edema and anoxia. He succumbed in respiratory collapse and pulmonary edema approximately 24 hours after operation.

Autopsy revealed that the heart weighed 380 gm. The leaflets of the tricuspid valve and the cusps of the pulmonary and aortic valves were thin and delicate. The chordae tendineae of the tricuspid leaflets were of normal appearance. The trabeculae carneae and papillary muscles of the right ventricle were moderately hypertrophied. There was some thickening of the wall of the right ventricle. The left auricle showed hypertrophy and dilatation of its wall. The leaflets of the mitral valve were interadherent with a resulting stenosis. The lumen, fish-mouthed in character, had a circumference of 3 cm. The chordae tendineae of the valve were markedly thickened and shortened. An operative defect in the medial portion of the base of the posterior leaflet measured 0.6 cm by 0.3 cm, it extended completely through the thick valve from the auricular to the ventricular surface. Grossly, the lungs were unusually firm. Microscopical examination revealed thickening of the alveolar walls, dilatation of the capillaries and increase in the interstitial tissue and pericapillary edema. These findings were consistent with those described by Parker and Weiss.<sup>29</sup> The spleen, kidneys, liver and gastrointestinal tract showed chronic passive congestion. Gross and microscopical study showed no abnormalities in the brain.

This case illustrates how completely even a carefully planned procedure can miscarry. The intended manipulation was carried out with dispatch, and the changes in the interauricular pressure were recorded. The result was disastrous. Even at autopsy it was not clear why the operation had caused a rise rather than a fall in the left auricular pressure and had resulted in pulmonary edema and death in twenty-four hours.

The anesthesia chart showed a pulse rate fluctuating from 90 to 110 at induction of anesthesia. The operation had started with a rate of 110, and the

rate had risen to 135 per minute before the intra-cardiac portion of the procedure was undertaken. It then rose steadily after the operation. This tachycardia had not been prevented by us, no doubt, the use of barbiturates, atropine and direct vagal block had increased the heart rate.

In the presence of tachycardia when the mitral orifice is stenotic or regurgitant, it seems possible that three factors tending to increase pulmonary vascular pressure can operate

The stenotic mitral orifice permits blood to drain through it at a limited maximum rate only. The flow from auricle to ventricle occurs only during diastole. The duration of each systolic contraction is essentially the same whether the heart rate is fast or slow, therefore, the increased total systolic time of tachycardia is at the expense of the total diastolic time. With a reduced total diastolic period, there is less time for auricle-to-ventricle drainage or flow. Thus the obstructive effect of a stenotic mitral valve is greatest during periods of rapid heart action.

The undamaged right ventricle may pump more blood into the lungs during tachycardia.

The total volume of regurgitant blood is a function of the number of systolic contractions. The more rapid the heart, the more numerous are the regurgitant jets and, in general, the greater insufficiency in terms both of volume of regurgitant blood and of effect of regurgitant pressure on the left auricle and pulmonary circulation.

In short, tachycardia tends to increase pulmonary blood pressure by greater obstruction to forward flow, greater pulmonary filling from the undamaged right ventricle and increased regurgitation or backward flow from the left ventricle.

These factors, simple as they seem now, were not fully appreciated until the disastrous effects of tachycardia in the first patient were observed. Subsequent animal experiments have confirmed their importance, and these will be reported later. It is evident that during any operation on patients with mitral stenosis and regurgitation, a slow heart rate must be maintained.

These considerations have a bearing, too, on the selection of patients for operation. Patients in Group B who are able to maintain a normal resting cardiac output may have predominant mitral regurgitation. If so, their condition would only be made worse by an increase in the degree of insufficiency surgically, by tachycardia or particularly by a combination of these. For the patients in Group C, the operation of cardiac denervation is a direct attempt to diminish the hazard that tachycardia presents. The more closely we observe patients with severe mitral disease, the more conspicuous is the association of tachycardia with bouts of "pul-

monary decompensation" such as paroxysmal dyspnea, pulmonary edema and hemoptysis.

The fourth principle is as follows: *in the presence of mitral obstruction or regurgitation, a rapid heart rate must be avoided, tachycardia tends to increase pulmonary vascular pressure and is associated with attacks of pulmonary edema or "pulmonary decompensation"*

The course of the second patient on whom valvuloplasty was performed illustrates that the procedure is feasible in human beings, perhaps the survival of this patient was aided by the measures taken to reduce tachycardia.

CASE 2 G A C, a 27-year-old man, was referred to the Boston City Hospital in June, 1948\*. The chief complaint was that of pain at the angle of the right scapula. Since the age of 8 years, he had had six attacks of "rheumatic fever," characterized by fever, chills and bone pain. With one episode he developed chorea and tender subcutaneous nodules. He had suffered from exertional dyspnea, palpitation of the heart and easy fatigability for 10 years at least. He had taken maintenance doses of digitalis since the early attacks in childhood. A chronic cough with occasional streaking of blood had occurred 3 years previously. At about that time, pain in the back of the right side of the chest started. This was nonradiating and could be relieved at first by changes in position. However, it had become progressively worse during the 2 months prior to admission and was constant at the time of entry. The patient was almost completely invalided during this period.

Physical examination revealed an emaciated young man with a *cafe-au-lait* complexion. There was slight venous distention in the neck. The heart was greatly enlarged to the right and left, and the rhythm was typical of auricular fibrillation with a rate of 110 and some pulse deficit. A soft diastolic rumble was heard from the lower end of the sternum to the apex. Near the apex, the murmur was loud and rough and there was a pronounced diastolic thrill. The pulmonic second was greater than the aortic second sound. The area of liver dullness appeared to be increased. There was no peripheral edema. The blood pressure was 110/65.

Six-foot teleroentgenograms revealed a greatly enlarged heart to both right and left. The left auricle was markedly enlarged. There was fluid in the right costophrenic angle. Films showed areas of patchy density in the right-middle and lower-lung fields, probably owing to atelectasis. The electrocardiograms showed auricular fibrillation and diphasic T waves, with low origin of Leads 1, 2 and 4. The venous pressure was equivalent to 180 to 230 mm of water. The circulation time was 12 seconds (arm to lung) by the ether method. The hematocrit was 36 per cent. The vital capacity was 2.7 liters and dropped to 2 liters after exercise, when the pulse rate was elevated to 140. Measurement of the resting cardiac output by cardiac catheterization showed it to be low (3.4 liters per minute with a cardiac index of 2). With mild exercise the stroke volume decreased from a resting level of 52 cc. to 29 cc. The pulmonary-artery pressure was elevated (71 systolic, 39 diastolic and 51 mean) and showed a further increase during exercise. Evidence of right ventricular failure was afforded by the elevated resting right auricular pressure (8 mm of mercury), which increased to 9.5 mm after 1 minute of mild exercise and to 18.5 mm on manual pressure over the right upper quadrant.

In view of the general condition and the results of the physiologic studies, valvuloplasty was considered indicated.

Operation was performed on June 16. Premedication included 100 mg of seconal, 100 mg of demerol and 0.5 mg of scopolamine. Induction was uneventful with nitrous oxide and cyclopropane, endotracheal anesthesia was maintained with ether. The heart rate was followed continuously by electrocardiographic tracings. The patient was placed in the dorsal decubitus position. A left anterior intercostal approach through the third space was carried out, with division of the second and third costal cartilages at the sternum. Firm adhesions held the lung to the chest wall. The pericardium was opened transversely down to

\*Referred by Dr. Sawyer Foster of Boston, Massachusetts.

the phrenic nerve. The left lateral aspect of the left auricle and the left auricular appendage were exposed by freeing diffuse adhesions to the pericardium. A pulmonary conus perhaps three times the normal size presented anteriorly. Three No. 000 silk purse-string hemostatic sutures were placed around the auricular appendage at the projected cardiomyotomy site. Through this prepared site in the tip of the left auricular appendage a trocar and cannula (Fig. 7) were then introduced, the trocar was removed, a manometer was attached to the cannula, and the interauricular pressure found to be equivalent to 450 mm. of saline solution at a pulse rate of 92. The cardiovalvulotome (Fig. 7)

FIGURE 8 Patient in Case 2 Two Months after Mitral Valvuloplasty

was introduced with the cutting edge directed at the lateral commissure, the valvulotome hook engaged, and the instrument closed. The cutting sensation and sound were elicited, but the segment was not recovered. The maneuver was repeated with the instrument directed at the medial commissure. Finally, a segment of the stenotic funnel was removed in a third maneuver directed at the posterior aspect of the lateral commissure. After these three intracardiac cutting manipulations, the interauricular pressure was again taken and found to be equivalent to 400 mm. of saline solution even though the pulse rate had risen to 108. During these five intracardiac procedures, 40 mg. of procaine was given twice intravenously. Upon completion of the intracardiac manipulations, the instruments were withdrawn, and the cardiomyotomy site was sealed by tying the purse-string sutures. The closure of the auricle was reinforced by the pericardial closure in that zone. The remainder of the pericardial incision was loosely closed to allow the escape of any effusion. The anterior thoracotomy incision was closed in layers in a routine fashion, without drainage.

The postoperative course was uneventful, and the patient was subjectively improved during his immediate hospital convalescence. The pain that represented his chief complaint on admission disappeared, and he seemed to have an increased exercise tolerance.

The first objective studies made since the operation show little improvement in cardiac function over that prior to operation. The size of the left auricle has not diminished. Follow-up studies will be reported.

This operation was directed at increasing the size of the mitral orifice itself. That the patient would benefit by this procedure was suggested by the low cardiac output and the stroke volume that decreased with exercise. The principle of increasing the size of the mitral orifice and yet producing "selective insufficiency" was combined with an attempt at removing the immobilizing commissures, the current crude form of "valvuloplasty." Intravenous procaine was given during the operation to reduce myocardial irritability and as a part of the effort to maintain a slow heart rate. The operation was uneventful, and the pressure studies at the time suggested a favorable response. Since operation, the patient has been dramatically improved subjectively, although such objective studies as have been made show little change from the earlier investigations.

Before operation it was known that the general condition of this patient made him a much worse operative risk than the first patient. However, operation was elected after the poor prognosis, the progression of symptoms despite a rigid medical regime and catheterization studies that suggested possible benefit through valvuloplasty had been considered. The four principles of surgery on the mitral valve were applied, and the commissures and one segment of the posterior leaflet of the stenotic funnel were removed. This patient is alive today, symptomatically improved, five months after operation (Fig. 8).

#### SUMMARY AND CONCLUSIONS

Numerous complex physiologic and morphologic factors are concerned in the production of symptoms in patients with mitral stenosis.

A preliminary classification is presented of patients incapacitated by mitral stenosis, who may be benefited by different types of surgery. Group A, patients with low fixed cardiac output—mitral valvuloplasty, Group B, patients with normal cardiac output—artificial interatrial shunt, Group C, patients with uncontrollable tachycardia or with anginal pain—cardiac denervation.

Five operations have been performed. Mitral valvuloplasty was performed in 2 patients of Group A, with 1 death. Artificial interatrial defects were produced in 2 patients of Group B, with survival in each case. Denervation of the heart by bilateral removal of the inferior cervical and dorsal first to fourth ganglions in 1 patient of Group C was followed by improvement.

These cases are now reported only to indicate the ability of such patients to withstand operation. The evaluation of any long-term benefits attributable to these procedures — and, indeed, of the ultimate position of surgery in mitral stenosis — must rest on objective criteria gained from hemodynamic studies carried out before and after operation. Subjective selection of patients and assessment of results lead to dangerous competitive exercises in surgical technics rather than to fundamental advances in therapy.

Four principles of the surgery of mitral stenosis have been evolved: the operation should be performed without dislocation of the heart from the position of optimum function, the button-hole opening of the stenotic mitral valve should be approached from the auricular side so that the funnel directs the cutting instrument toward the leaflet margin, surgical enlargement of the stenotic orifice should be so planned that there is a minimum burden from associated regurgitation ("selective insufficiency") and maximum restoration of valvular function ("valvuloplasty"), and in the presence of mitral obstruction or regurgitation, undue acceleration of the heart rate must be prevented — tachycardia increases pulmonary vascular pressure and is associated with attacks of pulmonary edema and other forms of "pulmonary decompensation."

An unsuccessful attempt at producing "selective insufficiency" is presented. It is suggested that tachycardia was an important factor in the disastrous outcome.

A case report is presented of the survival of a patient with mitral stenosis following an operation designed to produce "selective insufficiency" and "valvuloplasty" of the mitral valve.

The need for more extensive and more effective valvuloplastic technics is suggested.

We wish to express our appreciation for criticisms and suggestions to the following members of the Board of Consultants of The Heart Institute of the Sias Laboratories: Drs. Burton E. Hamilton, Frederic Parker, Jr., Richard Schatzki, and Paul M. Zoll.

# MEDICAL SCHOOLS AND THE QUALITY OF MEDICAL CARE\*

## A Survey of Recent Trends

E RICHARD WEINERMAN, M D , M P H †

BERKELEY, CALIFORNIA

**I**NCREASING attention has been paid in recent years to the economics of medical care. Proposals for newer health-service programs have stimulated a voluminous literature, and many important experiments in organized medical care have been developed to meet the increasing public demands.

Few students of the problem would quarrel with this emphasis upon costs and distribution of care. Ready access to adequate health services must exist for all the people.

The removal of economic barriers, however, would in itself not provide the whole answer to the medical needs of the country. There remains the challenging task of improving the *quality* of the service that is to be more equitably distributed. A serious gap persists between the standards of the teaching medical centers and the quality of care rendered in outlying and underprivileged communities.

In the effort to improve the general quality of medical care throughout the country, the medical schools are realizing the significance of the role they must play. This concept has been clearly expressed by the chairman of the Council on Medical Education of the American Medical Association<sup>1</sup> and by the secretary of the Association of American Medical Colleges.<sup>2</sup> In their emergence from the isolation of the last century, the schools developed close relations with universities and teaching hospitals. Now, such affiliations are beginning to extend to public health and social agencies, to smaller hospitals and health centers, and to practicing physicians in the surrounding area.

If improved quality is to accompany the better financing of medical care, and if the influence of the medical schools is to bear on the problem, this new and broader concept of the function of the school must be universally adopted. The basic functions of teaching and research expand to include the concept of service to the community, of active identification with the medical life of the surrounding region. The modern medical center becomes the hub of continuous postgraduate educational activities, of regional medical-service programs

reaching to outlying rural areas and of functional relations with all community health facilities. Thus, the quality of medical care may be enhanced throughout the region of the teaching center.

Such a development is neither new nor visionary. Many medical schools in this country have accepted responsibilities for improving medical standards in their areas. Several of the foreign nations are developing health-service regions around medical teaching centers. This report includes descriptions of some of the projects already underway in the United States in one phase or another of the general movement. Through broader orientation toward the preventive and social aspects of medicine, through continuous education of the physician and his technical aides and through functioning affiliations between metropolitan and small community hospitals, the quality of medical care available to the public is being steadily improved.

## UNDERGRADUATE MEDICAL TRAINING

In the fifty years since the development of the modern medical course, there have been vast and fundamental additions to the medical sciences. Whole new fields have opened up in nuclear physics, nutrition, tropical medicine, antibiotics, neurologic surgery and endocrinology—to mention but a few. Yet the “modern” medical curriculum existed in 1891, and prevailed in all schools by 1915. Since then, such development as has occurred has been somewhat haphazard and unplanned—often involving cumbersome additions to a fixed structure.<sup>3, 5</sup>

Increasingly apparent, moreover, in an industrialized, mobile society have been the interpersonal, social and environmental aspects of health and disease. The tremendous growth of organized systems of prepayment medical care, group practice, health units and preventive medical programs has changed the face of medicine, without producing very extensive alterations in the countenance of the medical schools. Notable exceptions to this rule are described below.

Such developments require parallel readjustments in the medical curriculum.<sup>6</sup> Fifty years ago, Johns Hopkins University School of Medicine made such a break with the educational *status quo* in introducing the “modern” curriculum. The stage is now set for the next step forward.

\*From the Department of Public Health Practice, Division of Medical Care, Harvard School of Public Health.

Much of the material in this paper was derived from the report on regional medical centers to the New York State Temporary Commission on Need for a State University (Young Commission) and is used with the permission of the Commission.

†Associate professor of medical economics, School of Public Health, University of California, formerly fellow Harvard School of Public Health.

### *Interdepartmental Integration*

The rapid growth of each field of medicine has often resulted in rigid compartmentalizing of the curriculum, with relatively isolated academic divisions each competing for the student's time and attention. If better equipped physicians are to be produced for modern medical practice, heed must be paid to the pleas of medical leaders for the development of integrated "vertical" medical courses.<sup>7-9</sup> Such a curriculum would stress the importance of "dynamic units of study"<sup>8</sup> instead of traditional departmental boundaries. Eadie and Davison<sup>10</sup> have urged a general course structure that is completely functional in concept, whereby each of the separate disciplines contributes to the total understanding of the subject under study.

Integration activities at the Bowman Gray School of Medicine may be mentioned by way of example of efforts in this field.<sup>11</sup> At this new school studies in basic science are being related to their sick-bed implications through medical and surgical clinics designed to illustrate the principles under discussion. The preclinical faculty members make hospital ward rounds, and residents in the various specialties are given teaching assignments in the basic-science courses. Departmental autonomy is increasingly relinquished. Similar efforts are under way at the Western Reserve University School of Medicine<sup>12</sup> and at a few others.

### *New Emphasis in the Curriculum*

Such general integration of the curriculum can go a long way toward improving the quality of the training offered. However, the requirements of modern medicine call for the addition of some specific new elements and the strengthening of others in the general medical courses. These are, significantly enough, the disciplines that examine the relations of the sick man to his fellows and his community. Their influence on the quality of professional care is fundamental.

### *Psychiatry*

Although the teaching of psychiatry has progressed in recent years, medical students are often inadequately provided with training in the understanding of the personal and emotional relations in health and disease. Undergraduate training in this field is too often restricted to a few mental-hospital case studies and a disjointed series of lectures on psychiatric disorders. A recent statement by nineteen medical-school deans declared "There are not five medical schools in the United States with Departments of Psychiatry adequately endowed."<sup>13</sup>

Still entirely undeveloped is the potentially much more productive field of mental hygiene. The medical student is now rarely impressed with an appreciation of the gigantic task to be performed through

preventive psychiatry — especially in childhood — in the control of mental disorders that fill no less than half the hospital beds of the nation. The recently passed National Mental Health Act provides funds for research and training in this field, and should serve as the needed stimulus to expanded undergraduate activity.

The teaching of psychiatry at University of Louisville School of Medicine exemplifies commendable efforts now underway in some schools.<sup>14</sup> Here psychiatric instruction permeates the entire course. The city mental-hygiene clinic is a part of the Department of Psychiatry, which includes three full-time teachers. The program involves seminars, clinical clerkships, home visits, observations of therapeutic interviews, participation in nursery-center operations and the like. Student participation remains the key to the program. More recently, sweeping reorganization of the psychiatric teaching program has been instituted at Yale University School of Medicine.

### *Preventive Medicine*

In a medical philosophy focused on disease and its treatment, the promotion of health and the prevention of illness receive country-cousin attention. Almost every medical educator has been constrained to point out that a fundamental preoccupation with disease — to the exclusion of efforts to prevent it — is a primary weakness of modern medicine.

A recent report<sup>15</sup> indicates that twenty-eight of the eighty-seven schools in the United States and Canada have no organized program for instruction in prevention, and most of the schools do not regard such emphasis as important. Teaching hours are often those that no other department wants, and the median number of clock-hours total only 1.9 per cent of the general curriculum. Little or no instruction is incorporated into the preclinical years, and such instruction as was reported is usually didactic, with little relation to the clinic, the health center or the community.

The recommendations of the Committee on the Teaching of Preventive Medicine and Public Health recognized that the objective was not to produce junior health officers but to imbue the embryo physician with the concept of positive health and with the philosophy of preventive medicine. A separate department with a full-time chief, having 4 per cent of the curriculum hours and 5 to 8 per cent of the total budget, was urged for all schools. Teaching in the preclinical years and full co-ordination with other clinical departments was strongly recommended. This seems modest indeed.

Dublin<sup>16</sup> has described the specific accomplishments of a forward-looking department of preventive medicine at Long Island College of Medicine. His course in preventive medicine embraces the full facilities of the nearby community public-health

center and is closely correlated with clinical teaching. Senior students spend full time for four weeks in this work—participating in health clinics, field activities, seminar discussions, home visits and social-work programs.

Similar affiliations of local health units with departments of preventive medicine operate at Louisville, Cornell, New York University, Alabama, Manitoba and a few other schools of medicine. In this connection, Goodenough<sup>17</sup> and many others have stressed the very real importance of student health services as a practical demonstration of preventive technics and an opportunity for student participation in a program of health conservation.

### *Social and Economic Aspects of Medicine*

By the intelligent development of courses in socioeconomics, medical schools can overcome the single most serious deficiency in the modern system of medical education. The need for such new emphasis has been succinctly expressed by LeBlanc<sup>18</sup>

Somewhere along the line of medical education, the embryo doctor should come in contact with the economic facts of life. Medical students are, from an economic standpoint, a favorably selected group. They come from higher strata rather than the lower. It is not only likely, but experience has shown it to be true, that they know little or nothing about the economically underprivileged. Even in their dispensary work they are seeing their patients in a frame far more flattering than normal. They have never seen or smelled bad housing, they know nothing of the reality of bad diets, of broken homes, of unemployment, of what it means when the breadwinner is sent to a hospital for a long stay, of the thousand and one things never seen at the hospital bedside or in the dispensary.

Yet, in twenty-two of the schools no time is devoted to medical socioeconomics, and the over-all number of clock hours devoted to the subject is 3.9 (median number = 1.5).<sup>19</sup> A recent statement by a medical student highlights the situation: "When confronted with the question 'What information would you like to have included in a course on health economics?', many of the students immediately retorted, 'What is health economics?'"<sup>20</sup>

Similarly, a survey conducted by the Association of Internes and Medical Students revealed an overwhelming desire on the part of the student sample for more instruction in these matters.<sup>21</sup> At Harvard, student interest manifested itself in a highly successful series of medical-sociology seminars organized and run as an extracurricular activity.

Many voices have been raised in recognition of this need. Allen,<sup>7</sup> Leavell,<sup>22</sup> Means,<sup>23</sup> Goldmann,<sup>24</sup> Gregg<sup>25</sup> and others<sup>26</sup> have forcefully stressed the need for the teaching of medical socioeconomics. Oxford University and the University of Brussels have established well known chairs in social medicine, as have other leading schools in Europe and Canada. A few of the schools in this country have already organized some instruction in this field.

One of the best known courses has been that at Yale, where—until recently—regular seminars have been offered in the subject.<sup>24</sup> A briefer orientation course is available at the University of Minnesota Medical School,<sup>27</sup> and a ten-hour elective is being offered at the University of Colorado School of Medicine.<sup>28\*</sup>

Medical socioeconomics should include instruction in the organization and administration of medical-care programs if new graduates are to be able to find their way logically through the turmoil of public discussion of these problems. The medical student should be acquainted with such modern phenomena as Blue Cross plans, group-practice associations, union medical-care projects, rural health co-operatives, veterans' services and welfare medical programs. The experience of foreign health-insurance systems should be analyzed, and current national legislation studied. Effective medical-care teaching can obviously be done best when the school itself is actively involved in the development of medical-service programs in which the students can participate. The value of medical-care activity in the medical school has been discussed in detail for Cornell University Medical College and New York Hospital by Pastore.<sup>29</sup> The affiliation of the New York University Medical Group with the health-insurance plan of Greater New York and of both Johns Hopkins and Maryland medical schools with the new Baltimore plan are cases in point.

In 1940, Gregg<sup>30</sup> gave the sharpest possible emphasis to this phase of medical training: "I venture to say that the order in which medical schools in this country organize seminars and courses on social medicine will be a serial registrar of the relative alertness of their administration."†

### *Community and Field Work*

Training in modern medicine is enhanced by the personal introduction of the student to the various health and medical activities of the community. Work in local health centers, public-health laboratories, social-welfare agencies, group-practice organizations, private practitioners' offices, industrial clinics and the like is invaluable experience for the developing practitioner. Similarly important are student visits to the home and job environments of the patients and co-operation with medical social workers. There seems to be a good reason for the suggestion that the summer months of medical school be devoted to such field observation and training<sup>8</sup> and not wasted during a generally overcrowded curriculum.

\*Greater attention to the subject of health economics and medical care is paid at some of the schools of public health, particularly at Michigan and more recently at Harvard. Plans for expanded work in health economics are now underway at Johns Hopkins, North Carolina and California Schools of Public Health.

†A careful study of social medical teaching in all American medical schools and a strong exposition of its importance has been recently released by an expert Committee of the Association of American Medical Colleges and the American Association of Medical Social Workers.<sup>31</sup>

Some of the schools have taken important initial steps to introduce their students to the extrahospital aspects of health and disease. At Harvard teaching centers (Massachusetts General and Beth Israel hospitals), special sessions are devoted during the clinical clerkship to the social and environmental aspects of the cases assigned for student work-up.<sup>23-26</sup> At the University of Pittsburgh, joint case investigations by both medical and social-work students have been organized.<sup>22</sup> The University of Syracuse has developed a plan whereby each clinical clerk must study intensively the complete socioeconomic background of at least one hospital patient, including contacts with appropriate community agencies.<sup>23</sup> Dalhousie University in Halifax requires that students visit patients' homes together with the public-health nurse and report on the implications of their findings.<sup>24</sup> At California and Wisconsin, fourth-year students are given opportunity to spend time with practicing rural doctors.

An approach to the goal of "harmonized" community health services has recently been described at the new four-year Medical College of Alabama.<sup>25</sup> The offices of medical school, teaching hospital, local health department, outpatient clinics, county hospital and medical society are physically as well as functionally united. Incorporated in the school buildings are also the offices of the voluntary health agencies and living quarters for students, staff and hospital residents.

## GRADUATE MEDICAL TRAINING

### *Internship and Residency*

The institution of intern and residency training marked a major step forward in medical education. Six schools in the United States and four in Canada require a year's internship for the degree of Doctor of Medicine, and twenty-three states have made it a requisite for the medical license. Today there is need for further improvement in the graduate training system. Medical schools have important opportunities for improving the quality of medical practice by broadening the scope of the hospital affiliations in which they are involved.

Of the 6280 registered hospitals in the United States, only about 300 are affiliated for teaching purposes with medical schools.<sup>26</sup> Yet over 1000 hospitals are approved by the American Medical Association for residency training,\* and over 800 for intern training.<sup>27</sup> It is apparent that significant improvements could be achieved if the medical schools were to increase their influence on the standards of graduate education in the nonaffiliated hospitals. Thus, both resident and visiting staffs would benefit from regular exposure to the best of clinical instruction. The concept of regional-

hospital networks, described below, lays the basis for such supervised training programs.

Jensen<sup>28</sup> has reported a valuable experiment in the provision of follow-up medical service for discharged hospital patients by a resident staff member. This experience not only improved the care of chronic cases and reduced the number of readmissions, but served to highlight the complex social and economic factors in each case. Similarly, some of the better teaching hospitals are attempting to improve the scope and vision of their graduate training programs by establishing domiciliary services, clinic experience and social-service conferences for the house staff. Plans for the rotation of the house staff through outlying local hospitals have been reported at Alabama, Michigan, Colorado, Tulane and Rochester and at many of the other schools described below.

## POSTGRADUATE EDUCATION AND COMMUNITY SERVICE

The most obvious and immediate contribution that a medical school can make to the quality of medical practice is in the field of postgraduate medical education. In a swiftly developing profession such as medicine, the greatest impediment to high standards of practice is the difficulty in keeping abreast of the times. The medical schools are therefore paying more and more attention to their postgraduate obligations.

The foundation of an effective system of postgraduate training again rests squarely upon the establishment of a co-ordinated regional network of health and hospital facilities—starting with the rural and community health centers, feeding into larger district hospitals, and converging upon a central base institution affiliated with a medical school. In such functional systems, continuous professional education can be carried on, and the influence of the best medical centers can reach the rural and suburban areas.

### *Regionalism in Health Services*

In a health-service region, the functionally unified medical "trade area" replaces the often unwieldy political unit. An integrated network of hospitals and health centers takes the place of the present haphazard relation of medical facilities. Throughout the nation, health-service regions can be delineated on the basis of such factors as administrative relations, geographic and population characteristics, transportation facilities, established health resources, natural lines of trade movements and current flow of patients to practitioners and hospitals. Within these broad regions, functional subdistricts can similarly be defined.

Each health-service region can develop within itself the elements of a self-sufficient and comprehensive health system. Community clinics, hospitals, public-health units, nursing homes and other

\*Including Army, Navy, Veterans Administration and Public Health Service hospitals.

facilities can co-ordinate into a service network that provides the individual practitioners with complete facilities and reaches all the people with adequate health care. The outlines of such a concept have been worked out by the United States Public Health Service,<sup>39</sup> a Senate committee on Wartime Health and Education<sup>40</sup> and the National Commission on Hospital Care,<sup>41</sup> among others. This principle has been given national impetus by the recent passage of the Hospital Survey and Construction Act, and has already been worked out in some detail by several states.

### *The Role of the Medical Center in the Health Service Region*

The hub of the proposed system of regionalized health services is the medical teaching center. The base hospital is the university-connected institution where teaching, research, specialized medical care and consultation services are integrated. The co-ordinated network of community-hospital and health-center facilities affords the school an ideal opportunity for student training in the socioeconomics of health and in the problems of everyday practice. In turn, the scientific activities at the teaching center stimulate improved standards of medical care throughout the region.

The flow becomes a two-way affair. Consultants and instructors can visit the community institutions, bringing to the local practitioners the needed professional contacts and opportunities for refresher training. Students and graduate trainees can participate at all levels of the system, carrying with them the freshness of recent studies, and learning at first hand about the opportunities and responsibilities of local practice. Laboratory, administrative and library aids can become available to the peripheral institutions.

On the other hand, there can be a steady in-flow of referred patients, diagnostic materials and health personnel from the outlying areas. Special laboratory and radiologic services can be concentrated at the regional centers. Physicians, dentists, nurses and auxiliary technicians can travel to the center for advanced training, refresher courses and special conferences. Co-ordinated record-keeping becomes possible. The teaching center can realize its fullest opportunities for continuous professional education and for service to the outlying areas of the region.

Such regional affiliations can do much to overcome the reluctance of younger, well trained physicians to settle in rural areas. Continuous contacts with the teaching center, available consultants, more adequate laboratory and x-ray aids and better local hospital facilities contribute to more desirable professional conditions. The attraction of competent practitioners to rural communities is an absolute essential in any effort to improve health services for the nation.

Finally, the regional system of co-ordinated metropolitan, district and local hospitals can approach the goal of group medical practice for sparsely settled and outlying areas. Obviously, a working group of physicians cannot be supported in a small, rural community. Through regional affiliations, however, specialists in the district and base centers can effectively co-ordinate with general practitioners in the rural localities. The high standards of modern, scientific teamwork medicine can thus be approached throughout the region.

Description of some of the existing experiments in regional planning may serve to illustrate this concept.

*The Bingham plan.* With the financial support of the Bingham Associates Fund, the Joseph H. Pratt Diagnostic Hospital and Tufts College Medical School have undertaken to co-ordinate medical care in nearby rural areas of Maine and Massachusetts.<sup>42</sup> Outlying community hospitals affiliate with regional hospitals in the larger cities. The teaching center in Boston is the hub of the system. Proger<sup>43</sup> has described the plan as one involving diagnostic hospital service, hospital extension services and postgraduate courses. Laboratory and diagnostic services are promoted in the periphery. Patients are referred centrally for diagnostic and occasional therapeutic aid. Local doctors and ancillary personnel move to the regional and Boston institutions for consultations, conferences and instructional courses. A centrifugal flow of technical aids and teaching personnel proceeds concurrently.

Emphasis is placed upon continuous education of the community physician through detailed case reports, follow-up literature, visiting ward rounds, conferences and refresher courses. Tufts medical students are to be given experience in rural clinical clerkships, and plans are developing for the rotation of medical and surgical residents through the community hospitals.

*The Rochester plan.* A similar regionalization project has been financed by the Commonwealth Fund, centered around the University of Rochester Medical School and six hospitals in the City of Rochester, New York.<sup>44</sup> Seventeen community hospitals in the area have voluntarily affiliated in a regional scheme that involves referral of difficult patients to the medical center, travel by visiting consultants and professors from the University to the outlying districts, rotation of residents through the local hospitals, fellowships for local doctors, nurses and technical personnel to study at the center, and continuous teaching programs designed to meet the needs of busy practitioners. Grants of funds for plant expansions are available to the affiliated community hospitals. A somewhat smaller project at the Medical College of Virginia in Richmond incorporates the same principle.

*The Michigan plan.* For some years the University of Michigan has operated a program of affilia-

tion with outlying community hospitals. Clinical professors conduct "circuit courses" in the local institutions, and resident physicians from the smaller units return to the medical center for eight months of training in the basic sciences.<sup>45</sup> A similar plan for interns at small hospitals is now under discussion.

The University of Michigan Medical School, in conjunction with the State Medical Society, has also maintained since 1927 a department of postgraduate education. Brief refresher courses, summer-session institutes and individual instruction for practitioners have been part of a regional system since 1934. In the academic year 1937-1938 a total of 1957 practitioners participated in the program. A formal certificate of postgraduate education is now awarded for attendance at 60 per cent of the short courses over a four-year period.

*Other postgraduate programs.* The University of Minnesota has maintained a center for continuation study on its campus, where local practitioners may actually reside while taking short refresher courses.<sup>46</sup> In ten years of operation, 2700 postgraduate students have participated. Recently, this institution has pioneered in the training of general practitioners in psychiatry.

New York University has recently inaugurated a system of community-hospital affiliations with institutions suburban to the metropolitan center. With the aid of the Kellogg Foundation a program of residency training includes one year of academic study at the School and assignment of teaching consultants for periodic visits to the affiliated small hospitals.<sup>47</sup>

At the University of Colorado — again with Kellogg funds — a similar regional plan will co-ordinate rural hospitals with the university center. House officers preparing for general practice spend two years at the University Hospital and rotate through selected community hospitals during a third year. The medical school establishes standards and furnishes visiting teachers and consultants for resident (and visiting) staff instruction. This plan is a co-operative venture of the State Medical Society, the Hospital Association and the University.<sup>48</sup>

The Universities of Tennessee and Vanderbilt have co-operated with the Tennessee State Medical Society, the State Health Department and the Commonwealth Fund in supporting circuit courses for general practitioners throughout the State. The first circuit was attended by 46 per cent of the physicians in the State.<sup>49</sup> Fellowships are also available for more extensive courses of study.

A 1946 report of the New York State Health Preparedness Commission<sup>49</sup> has described in great detail the possibility for health regionalization throughout the State, again with the recommendation that the base centers be established in the medical schools.

Experiments in regionalism and postgraduate education have also been undertaken at Tulane, Bowman Gray, Iowa and Wisconsin. Several of the foundations, in addition to those already mentioned, have contributed to the support of these medical-school-hospital-service programs. The Duke Endowment has stimulated hospital co-ordination in the Carolinas, as has the Kellogg Foundation in Michigan. Various state medical societies have sponsored postgraduate sessions for local practitioners, including Connecticut, Idaho and North Carolina. In Canada, both Manitoba and Saskatchewan are developing provincial health services on the regional network principle.

*The North Carolina proposals.* The medical commission chosen to consider the question of expanding to a full four-year school the present basic-science course at the University of North Carolina rendered an affirmative majority report primarily on the basis of the potential value of a state-wide health-service program that could be centered in the new school.<sup>50</sup> It was pointed out that new graduates could not be held in rural areas (a primary need in the State) unless a program were established to provide them with the necessary facilities and professional contacts.

The plan as outlined includes an interrelated hospital network centered around the state medical school, similar in design and function to the program at Tufts. One weakness of existing regional programs has been recognized in the Commission's strong recommendation that close co-ordination with the preventive services of public health agencies be maintained at every level.

An important additional feature, moreover, has been proposed to overcome the economic weakness of the other regional projects. Basic financial problems have continually threatened the success of existing hospital network and postgraduate educational systems. Outlying physicians are not always anxious to refer patients to district medical centers if this entails "losing" the case. Large numbers of the people cannot afford to utilize the hospital network even when it does exist. New health centers and local hospitals cannot be constructed and maintained in communities with deficient medical purchasing power, just as the best of regional plans will not attract to rural areas the doctors who cannot obtain decent incomes there.

Essential to the success of the new concept, therefore, is the establishment of organized systems of group prepayment and tax-supported medical care. Such a unified state-wide plan of financing is the recommendation of the North Carolina Commission. Thus, the facilities can be fully utilized by all the people of the region, and physicians would face no great economic hardships in choosing for practice the particular localities most in need of their services.

facilities can co-ordinate into a service network that provides the individual practitioners with complete facilities and reaches all the people with adequate health care. The outlines of such a concept have been worked out by the United States Public Health Service,<sup>39</sup> a Senate committee on Wartime Health and Education<sup>40</sup> and the National Commission on Hospital Care,<sup>41</sup> among others. This principle has been given national impetus by the recent passage of the Hospital Survey and Construction Act, and has already been worked out in some detail by several states.

### *The Role of the Medical Center in the Health Service Region*

The hub of the proposed system of regionalized health services is the medical teaching center. The base hospital is the university-connected institution where teaching, research, specialized medical care and consultation services are integrated. The co-ordinated network of community-hospital and health-center facilities affords the school an ideal opportunity for student training in the socioeconomics of health and in the problems of everyday practice. In turn, the scientific activities at the teaching center stimulate improved standards of medical care throughout the region.

The flow becomes a two-way affair. Consultants and instructors can visit the community institutions, bringing to the local practitioners the needed professional contacts and opportunities for refresher training. Students and graduate trainees can participate at all levels of the system, carrying with them the freshness of recent studies, and learning at first hand about the opportunities and responsibilities of local practice. Laboratory, administrative and library aids can become available to the peripheral institutions.

On the other hand, there can be a steady in-flow of referred patients, diagnostic materials and health personnel from the outlying areas. Special laboratory and radiologic services can be concentrated at the regional centers. Physicians, dentists, nurses and auxiliary technicians can travel to the center for advanced training, refresher courses and special conferences. Co-ordinated record-keeping becomes possible. The teaching center can realize its fullest opportunities for continuous professional education and for service to the outlying areas of the region.

Such regional affiliations can do much to overcome the reluctance of younger, well trained physicians to settle in rural areas. Continuous contacts with the teaching center, available consultants, more adequate laboratory and x-ray aids and better local hospital facilities contribute to more desirable professional conditions. The attraction of competent practitioners to rural communities is an absolute essential in any effort to improve health services for the nation.

Finally, the regional system of co-ordinated metropolitan, district and local hospitals can approach the goal of group medical practice for sparsely settled and outlying areas. Obviously, a working group of physicians cannot be supported in a small, rural community. Through regional affiliations, however, specialists in the district and base centers can effectively co-ordinate with general practitioners in the rural localities. The high standards of modern, scientific teamwork medicine can thus be approached throughout the region.

Description of some of the existing experiments in regional planning may serve to illustrate this concept.

*The Bingham plan.* With the financial support of the Bingham Associates Fund, the Joseph H. Pratt Diagnostic Hospital and Tufts College Medical School have undertaken to co-ordinate medical care in nearby rural areas of Maine and Massachusetts.<sup>42</sup> Outlying community hospitals affiliate with regional hospitals in the larger cities. The teaching center in Boston is the hub of the system. Proger<sup>43</sup> has described the plan as one involving diagnostic hospital service, hospital extension services and postgraduate courses. Laboratory and diagnostic services are promoted in the periphery. Patients are referred centrally for diagnostic and occasional therapeutic aid. Local doctors and ancillary personnel move to the regional and Boston institutions for consultations, conferences and instructional courses. A centrifugal flow of technical aids and teaching personnel proceeds concurrently.

Emphasis is placed upon continuous education of the community physician through detailed case reports, follow-up literature, visiting ward rounds, conferences and refresher courses. Tufts medical students are to be given experience in rural clinical clerkships, and plans are developing for the rotation of medical and surgical residents through the community hospitals.

*The Rochester plan.* A similar regionalization project has been financed by the Commonwealth Fund, centered around the University of Rochester Medical School and six hospitals in the City of Rochester, New York.<sup>44</sup> Seventeen community hospitals in the area have voluntarily affiliated in a regional scheme that involves referral of difficult patients to the medical center, travel by visiting consultants and professors from the University to the outlying districts, rotation of residents through the local hospitals, fellowships for local doctors, nurses and technical personnel to study at the center, and continuous teaching programs designed to meet the needs of busy practitioners. Grants of funds for plant expansions are available to the affiliated community hospitals. A somewhat smaller project at the Medical College of Virginia in Richmond incorporates the same principle.

*The Michigan plan.* For some years the University of Michigan has operated a program of affilia-

*The Long Island proposals* Similar vision has been evidenced in the comprehensive program recently announced by the Long Island College of Medicine.<sup>51</sup> This project envisages a regional system throughout the Brooklyn and Long Island area, financed by voluntary prepayment and served by group-practice units in co-ordinated health centers. Major emphasis is laid on preventive services and family-health maintenance. Continuing professional education would be carried on throughout the region. Courses for nurses, technicians, dietitians and so forth would be regularly available.<sup>51</sup>

#### FINANCIAL CONSIDERATIONS

Serious discussion concerning the development of all such programs must, unfortunately, be prefaced with a word concerning finances. Any effort to extend the effective sphere of influence of the medical school must face the facts of budgetary handicaps in current training programs. The financial situation of the American medical schools is "desperate," according to the recent conference of the Council on Medical Education and Hospitals.<sup>13</sup> In a recent volume Allen<sup>7</sup> has declared that "the medical schools of this country will need to double their budgets for teaching and research by 1960." Certainly, any significant progress in medical education depends upon far more adequate financial support.

In 1943 the most heavily endowed institutions had ten times the operating budget of the poorest schools, and expended six times as much per student.<sup>52</sup> Private endowments and foundation funds are diminishing. Tuition fees are at an all-time high and yet cover only 28 per cent of total costs.<sup>13</sup> In this situation, much consideration is being given to the advantage of federal and state aid for medical education and research. Ample precedents for such orderly, acceptable and "nonregimenting" public aid exist in the thirty-odd state-university medical schools and in the grant programs of the United States Public Health Service and the Veterans Administration. Without some source of increased funds, the schools will find it difficult to meet the vast challenges of the day.

There is much to justify the application of public resources to the training of professional personnel. Medicine is being increasingly recognized as a "social" as well as a "natural" science—a discipline that must be as devoted to the protection of the health of the community as to the care of the sick individual. As health administrators, as advisers to statesmen, educators and law courts and as attendants in every phase of community life, physicians must fulfill an ever-expanding public role. New trends in medical-care planning, in industrial health programs and in international organizations call for even greater numbers of publicly responsible doctors. It does not seem inappropriate,

therefore, that society assume a share of the responsibility for training these kinds of physicians, and that the medical school devote itself actively to the broad social orientation of its students and to the promotion of the highest standards of medical service throughout the region. A medical school endeavoring to serve as the focal point of a regional medical-care plan that involves care of welfare clients, co-ordination with public agencies and general service to the community would logically qualify for public financial assistance.<sup>51</sup>

The democratic principle of full and equal opportunity for persons from minority and economically underprivileged groups who wish to study medicine is, of course, another powerful justification for such aid. Only through more adequate financing of medical schools can adequate scholarship grants and loans become available to those now unable to overcome the financial barriers to medical education.

#### THE MEDICAL SCHOOL OF THE FUTURE

The portrait of the new university medical school can now, perhaps, be drawn. Basically a service to the entire community, such a medical school will exist as the hub of a network of interrelated hospitals and health centers extending to the most isolated districts. Co-ordination with public-health and private-health and medical-care agencies will reflect the co-operative relations fostered between physicians and other health personnel. The students, chosen on the basis of broad academic preparation, demonstrated intellectual ability and qualities of personal integrity, will train in unified and noncompartmentalized courses that give adequate stress to the social and economic implications of modern medicine. Graduate and postgraduate educational programs will bring the knowledge of recent advances to local practitioners and afford younger residents some experience with the problems of rural and urban extrahospital practice. Research activities will continually elevate the standards of service. Through the co-ordinated network of medical facilities, the school will participate directly in the promotion of health and the provision of medical care throughout the area. Augmented public and private financial support to medical teaching centers will demonstrate an increased awareness of the broad social values that will accrue.

Thus, teaching centers may contribute effectively, continuously and lastingly to the quality of the medical service that is rendered to the people.

and a physical examination performed. All were found free of a history of liver disease and of significant physical abnormalities. Blood counts, a bromsulphalein excretion test (using 5 mg of dye per kilogram of body weight) and an initial sedimentation rate were found to be normal in all (Table 1). Also, routine urinalysis on each subject was entirely normal.

On completion of these examinations, each subject was put on a daily dose of dicumarol. Daily prothrombin times were determined on the undiluted plasma of each, with the use of thromboplastin prepared in our laboratory from human brain by a method derived from the Quick<sup>3</sup> acetone extraction technic. The prothrombin concentrations were maintained so far as possible, between 30 per cent and 10 per cent of mean normal, since these are the levels most commonly accepted as the limits of therapeutic range. All subjects tolerated the drug well, and were carried on it for twenty-five consecutive days. The sedimentation rates were determined on twenty-one of the twenty-five days, by the use of the Westergren method, in which the upper limit of normal in male subjects is considered as 15 mm per hour and 4 mg of po-

tassium oxalate and 6 mg of ammonium oxalate per each 5 cc of blood being used as anticoagulant.

## RESULTS

In none of the 5 subjects was there an elevation of the sedimentation rate above the upper limits of the normal range (Table 2).

## SUMMARY

The results of this study indicate that dicumarol administered in therapeutic dosage for twenty-five consecutive days has no significant effect on the erythrocyte sedimentation rate in normal men. It is possible that the results of this study cannot be applied to the interpretation of the effect of dicumarol on the sedimentation rates of patients with associated diseases that are known to affect the sedimentation rate.

# MEDICAL PROGRESS

## OTOLARYNGOLOGY

CARLYLE G. FLAKE, M.D.\*

BOSTON

IT IS the purpose of this review to present in summarized form certain papers on subjects of current concern in the field of otolaryngology and others that may be of more general interest. These papers appeared in the literature for the year 1947.

### THE EAR

#### Fenestration Operation

Moorhead<sup>1</sup> reported a series of 123 patients upon whom the fenestration procedure had been performed. The results were estimated on the basis of audiometer readings taken at 512, 1024 and 2048 cycles. In this group 29 per cent of patients failed to recover satisfactory hearing for any of the three tones. Forty-seven per cent recovered serviceable hearing with perception at the 30-decibel level or better for all three tones. Fifteen per cent improved to the extent that their threshold for two or three tones reached the level of 30 decibels or better.

\*Instructor in Laryngology, Harvard Medical School; chief, Division of Otolaryngology, Children's Hospital; otolaryngologic surgeon, Peter Bent Brigham Hospital.

In general 76 patients (62 per cent) were classed as having had successful results. The two main causes cited for poor results in suitable patients were closure of the new window by formation of new bone or by the development of fibrous tissue or both, and secondary postoperative serous labyrinthitis. No deaths occurred in this series, and although 2 patients developed facial paralysis, this complaint was transient.

From the many reports of the fenestration operation that have appeared in the literature, it becomes evident that satisfactory results may be achieved in a sufficiently high percentage of cases to warrant the operation in suitable patients. According to Lindsay<sup>2</sup> the three problems that remain to be solved are the establishment of criteria for assessing the possibilities of improvement in each case, the maintenance of a fenestra that will give maximum function and the prevention of injury to the sense organ of the ear as a result of the operation. In Lindsay's experience, patients most suitable for operation are young persons with relatively

# THE EFFECT OF DICUMAROL ON THE ERYTHROCYTE SEDIMENTATION RATE IN NORMAL MEN\*

JAMES L. PALMER, M.D.,† AND SVEN M. GUNDERSEN, M.D.‡

HANOVER, NEW HAMPSHIRE

OUR interest in the possible effect of dicumarol [3, 3'-methylenebis (4-hydroxycoumarin)] on the erythrocyte sedimentation rate in human beings was aroused when we began to use the drug in an increasing number of cases of acute myocardial in-

had no answer for it, and were unable to find a satisfactory answer in the literature.

Current opinion holds that the erythrocyte sedimentation rate is determined in large measure by the various fractions of the plasma proteins. Since

TABLE 1 Data before the Administration of Dicumarol

fraction. Experience suggested that the sedimentation rates in the patients receiving dicumarol remained elevated over a longer period than would otherwise have occurred, especially when judged in terms of general clinical progress. As is well

dicumarol affects the level of at least one of these fractions — that is, prothrombin — it seemed logical to assume that it might in some manner affect the sedimentation rate. Barker<sup>1</sup> stated in 1945 that dicumarol probably increased the sedimentation

known, the sedimentation rate is one of the most valuable of the available tests in following the course of these patients. When the question of the influence of dicumarol on this test was raised, we

rate, but he now believes that it probably does not.<sup>2</sup> Because of the dearth of information on the subject, we decided to test the effect of the drug on the sedimentation rate of normal persons.

## METHODS

Five healthy medical students volunteered as subjects. On each a thorough history was taken,

\*From the laboratories of the Mary Hitchcock Memorial Hospital and Dartmouth Medical School.

†Resident in medicine, Mary Hitchcock Memorial Hospital.

‡Physician, Mary Hitchcock Memorial Hospital and Hitchcock Clinic.

mechanism is intact and that the cochlear mechanism is not necessarily lost, for hearing islands may develop later in such patients. Deafness in children should be diagnosed, and the educational treatment started before three years of age. Even the completely deaf child can be taught lip reading and effective speech, and the use of a hearing aid enables those with some residual hearing to learn intelligible and not unpleasant speech. It has been proved practicable to teach an entirely deaf child about 1350 words so that he can speak 500 or 600 words when ready for the first grade. Oral communication is now recognized as the only rational approach for the deaf child. Lip reading is being replaced by speech reading because the development of speech is almost impossible without it. Effort is made to teach the deaf child to read the play of expressions on speakers' faces in terms of concept. The child must learn to hear with his eyes and reply in speech. The parents of deaf children must be taught to treat their children as normal and talk to them as much as possible.

### *Pellagra*

Observations made on the effects of starvation diets in a group of prisoners of war in Java, Batavia and Sumatra were reported by de Raadt.<sup>6</sup> From an otoneurologic viewpoint the chief symptoms were vertigo, nystagmus, headache, hearing impairment and weakness of lateral gaze and of convergence. Of 160 patients showing this syndrome, 101 complained of dizziness. Of the latter, 39 had typical rotary labyrinthine vertigo. The attacks varied in intensity and lasted from a few minutes to several days. At times the additional symptoms of nausea, vomiting, tinnitus and deafness were present. Profuse sweating and headache were often noted. Nystagmus was always present, generally of the first degree and in both directions. All forms of dizziness, especially the rotary vertigo, were initiated or increased by conjugate movement of the eyes. Forty-five patients complained of deafness, which was generally moderate and not annoying. One prisoner of war with perfect hearing when he entered the camp became totally deaf for conversational voice but subsequently almost completely recovered his hearing when nutritional conditions improved. Studies showed that the lesion in these patients was localized to the brain stem and that pellagra was the causative factor. The symptom complex observed was an early manifestation of that disease. It was suggested by de Raadt that any patient showing idiopathic vertigo of central origin should receive anti-pellagra therapy until the origin of the vertigo was determined.

### *Associated Keratitis*

Lewis<sup>7</sup> reported a clinical syndrome occurring in three young women and consisting of bilateral acoustic neuritis associated with interstitial kera-

titis. Allergy, dietary deficiency, syphilis and other chronic diseases were ruled out. In each patient the syndrome was characterized by a nonsyphilitic interstitial keratitis, vertigo, tinnitus and deafness. The acoustic neuritis terminated after a few months in complete bilateral nerve deafness and loss of vestibular function. The keratitis did not change appreciably in a year. The etiology was not determined, and the possibility of a virus infection could not, therefore, be excluded. In 1 patient cervical sympathetic ganglionectomy was performed early in the course of the disease without beneficial effect.

### *Multiple Sclerosis*

Hearing defects in patients with multiple sclerosis were studied by Von Leden and Horton.<sup>8</sup> Fifty-seven per cent of a series of 92 patients had normal hearing, whereas the remainder showed a measurable degree of deafness (25 decibels or more) in one or both ears. Of a similar group of normal healthy subjects tested under the same standard conditions, 18 per cent showed slight changes in auditory acuity in contrast to the varied changes found in 43 per cent of the patients with multiple sclerosis. Different types of auditory involvement were noted, including moderate to severe unilateral field defects up to 70 decibels. The decreased hearing in the speech range did not extend beyond the critical level of 70 decibels. This retention of hearing in the conversational range accounts for the fact that only 12 patients complained of poor hearing and that only 7 of these actually had defective hearing. This dissociation of subjective and objective disturbances is characteristic of multiple sclerosis. No relation appeared to exist between the hearing impairment and the severity of the disease. It was noted that disturbances of vestibular function provide a fairly accurate indication of changes in the patient's general condition.

### THE LABYRINTH

#### *Streptomycin*

A series of 81 patients from a large military hospital who had been treated with streptomycin for a variety of diseases were examined by Fowler and Seligman<sup>9</sup> for evidence of changes in the hearing and vestibular function. Those with known disease of the ear were excluded from the study. The diseases for which streptomycin had been given included osteomyelitis (71.6 per cent of cases), urinary infections (16.3 per cent) and miscellaneous conditions. The daily dose was usually 3 gm of streptomycin administered intramuscularly in divided doses. Total individual dosage was small in comparison with that given in tuberculosis and ranged from less than 10 gm to 49 gm, although 1 patient received a total of 141 gm. The interval between cessation of treatment and the initial otologic examination varied from one day to six months. Fifteen of the patients

better hearing for high tones than for low tones and a bone-conduction threshold within the normal range up to the 4000-cycle frequency or beyond. The hearing in this type of patient may, postoperatively, reach within 15 decibels of normal in the speech frequencies. The main problem in estimating bone conduction in otosclerosis arises when there is much asymmetry between the two sides. The bone-conduction threshold is then likely to reflect the better ear unless masking is adequate. It is questionable whether masking can be reliably carried out for bone-conduction sounds. It is also questionable whether an air-conduction hearing loss of over 60 decibels can occur without some impairment of the perceptive apparatus. In the series of cases reported the consistent finding of a depressed threshold for bone-conducted sound proved to be a reliable indication of the possible failure to obtain adequate and permanent improvement by fenestration. The possibility of improvement in speech perception appears to be most accurately indicated by the preoperative bone-conduction threshold values of 2048 and 1024 cycles

#### DEAFNESS

##### *Occupational*

MacLaren and Chaney<sup>3</sup> found, in a noise survey in an industrial plant, that sounds at levels of above 100 decibels are common in metal fabrication and that riveting is an important source of half this noise. Industrial noise also appears to be of the broad-spectrum variety, without prominent frequency peaks or narrow frequency bands. The borderline between relatively harmless noise and that which produced steady deterioration was found to lie in the region of 100 decibels. An analysis of 5000 audiograms made on workers in an airplane manufacturing plant showed that certain types of hearing loss increased greatly in the presence of intense noise. The greater portion of hearing loss took place within a few days or even a few hours of exposure and, at first, involved frequencies above 2048 cycles per second. Later, the loss extended to lower frequencies but at a much slower rate. After removal from the noise the lower tones were the first to return, followed by recovery of the high tones provided the damage had not been too great. In every group there were persons who did not show acoustic trauma even at the highest level encountered, fewer such cases were found as the noise intensity rose. Ear protectors that attenuated the higher frequencies, enough to bring over-all loudness below 100 decibels, allowed a measure of recovery from the trauma. The presence of conductive deafness did not seem to be an important factor in relation to development of occupational deafness. It was thought that the defect of conduction might result in some protection to the cochlear mechanism and that persons with this form of hear-

ing loss probably do not need to be excluded from noisy areas. As a preventive measure the authors recommended that when noise levels regularly exceed 100 decibels pre-employment audiograms be obtained, audiometric studies should be repeated at monthly intervals until it is determined what sort of equilibrium the employee can attain. Progressive deafness after six months calls for transfer to quieter surroundings. Should an early marked loss appear in the region below 2048 decibels, the worker should be removed to a quieter place.

##### *Rubella*

Further confirmation of the results of maternal rubella in producing deaf mutism in the offspring is reported from England by Clayton-Jones.<sup>4</sup> In a small school with 18 children the mothers of 8 gave a definite history of rubella in the second to fourth month of pregnancy, 1 mother gave a probable history. All the 8 children were born between August and October, 1940. In three larger schools a history of rubella was obtained from the mothers of 11 of 123 children. The 11 children were born between October, 1940, and February, 1941. Deafness noted in these children was bilateral and of the inner-ear type. It was incomplete and usually fairly uniform throughout the frequency range. Difficulty in feeding during infancy was commonly reported, and examination showed a tendency to deformity of the jaw, pigeon chest and atonic musculature. Intelligence appeared to be unaffected. No cataract or definite heart lesion was detected. The health records of the city of Manchester, England, show that the rubella epidemic of 1940 was peculiar in that an unusually high proportion of young women were affected.

##### *Pre-School*

Goodhill<sup>5</sup> states that hearing tests in children are based on psychologic principles since audiometry is useless up to the age of three and of limited value in children three to four years of age. Young infants are examined by the eye-reflex test. Various sounds are made by an assistant, who stands behind the child while the latter's attention is diverted. Hearing is indicated by involuntary blinking or jerking of the eyeball. The attention of a child two or more years old is diverted, and his name called in various tones. Hearing is demonstrated by eye responses or turning of the head toward the sound. Drums, whistles, bells and other sound-producing sources are used to test the frequency-response ranges, or a frequency-modulated loud speaker may be used. It is important that vestibular function be estimated in children who do not respond to sound stimuli, to detect possible hearing islands that may be amplified by a hearing aid in future training. The Kobrak cold-stimuli test can easily be done even on an infant. A normally active response indicates that the vestibular neurologic

night or during periods of inactivity. Warning of an impending attack, which was noted in about 50 per cent of the patients, took the form of an alteration in the character of the tinnitus or deafness and, in some patients, of a feeling of fullness or numbness behind the affected ear. Vertigo was the major symptom and consisted of a sensation of movement of surrounding objects—less commonly, of the subject himself rotating. Duration of the attacks varied from a few moments to several days and in severity from momentary inconvenience to helplessness. Unconsciousness occurred in only 2 cases. The caloric test rarely failed to reveal a lack of balance between the two labyrinths, the commonest finding being a depression of function on the side of deafness. In approximately 10 per cent of the patients in this series the caloric test revealed definite bilateral vestibular involvement. Medical treatment was given a trial in all cases and in the majority was sufficient to control the attacks. Phenobarbital and small doses of hyoscine were often helpful in modifying the attacks. Exclusion of salt and salty foods from the diet together with the limitation of fluid intake offered more relief than any other form of conservative treatment. When the attacks could not be controlled by medical means, surgical ablation of the offending labyrinth was carried out in patients in whom only one vestibular labyrinth was affected. This procedure was employed in 116 patients without any untoward operative results. After operation some residual dizziness, particularly on sudden head movements, was generally experienced. However, most patients were well enough to return to work within a period of two months of their operation.

Since various conditions causing vertigo are difficult to differentiate, Williams<sup>12</sup> suggests that a diagnosis of endolymphatic hydrops (Ménière's disease) should not be made until certain diseases and conditions have been ruled out. These are as follows: the presence of impacted foreign bodies or inspissated serum in the external auditory canal, obstruction of the eustachian tube on the affected side, multiple sclerosis, and Brun's syndrome of occlusion of the fourth ventricle by cysticercosis. The methods of medical treatment that have succeeded in relieving symptoms of endolymphatic hydrops have been based on the conception that this condition is a form of allergy. In acute attacks a few minims of epinephrine given intravenously have proved effective, as have rather large doses of atropine (0.86 mg). Benadryl has been found moderately effective in some patients. Williams has found that with either nicotinic acid or histamine results superior to those obtained by controlling water and electrolyte metabolism may be obtained. However, there is no obvious reason why these various methods should not be combined. It was therefore suggested that the total fluid intake be limited to 3000 cc daily, preferably less, that care be taken that the drinking water does not

contain excessive amounts of the sodium ion and that salty foods and the addition of salt to cooked foods be avoided. Potassium nitrate, 1 or 2 gm in enteric-coated tablets, is given three times a day with meals, and nicotinic acid is administered subcutaneously, starting with 25 mg and increasing by this amount with each injection until a dose that relieves symptoms is reached. In most instances this has been found to be 100 mg. However, some patients are unable to tolerate this amount, whereas others may require doses as high as 200 to 300 mg daily. Treatment with the vasodilators should not be continued longer than six months, without a rest period of several weeks since many of the vasodilators lose their efficiency when administered for longer periods. On this regimen and with judicious psychiatric treatment to relieve the anxiety-tension state, approximately 80 per cent of patients were relieved of their symptoms. In cases in which all types of medical treatment had failed, ablation of the labyrinth has proved the most effective treatment.

The vertigo<sup>14</sup> of Ménière's disease (labyrinthine hydrops) is so characteristic that it should not be confused with any other type. The typical symptom is a violent vertiginous seizure, which is paroxysmal and disabling. In contrast the vertigo in intracranial disease is more in the nature of a swimming, giddy or unsteady feeling, present most of the time but aggravated by sudden motion. Vertigo may be produced by organic central-nervous-system lesions. Such lesions are usually associated conspicuously with other clinical evidence of intracranial disorder, cerebellopontile-angle tumor is a classic example. Vertigo may be the symptom of a toxic condition. Evidence for this statement is in the occurrence of vertigo in septic patients after treatment with certain drugs such as the antibiotic streptomycin. It is often a manifestation of a nervous depression. There may be a large psychic factor in typical labyrinthine hydrops although it is probably the effect and not the cause of this syndrome. A vascular accident within the otic labyrinth may be the cause of an explosive attack of vertigo with a roaring noise in one ear, nausea, vomiting and unilateral deafness. All symptoms except the hearing impairment spontaneously disappear. Vertigo is occasionally seen in hypertensive disease. After splanchnicectomy in a series of 37 patients, most of the patients showed a marked decrease in hypertension and a disappearance of the associated vertigo. Symptoms of headache, dizziness, tinnitus and nervous irritability aggravated by fatigue and emotion are evidence of hypertensive disease and warrant the determination of the blood pressure at varying intervals.

#### OTITIS MEDIA

##### *Allergic Otitis*

In a series of 222 patients with manifest chronic otitis media, Koch<sup>15</sup> found that in 41 the secretion

were examined before and after therapy. Of the 81 patients studied, 42 showed a high-tone loss alone. Eleven patients showed a low-tone as well as a high-tone loss. The high-tone losses ranged from 30 to 100 decibels in the frequencies of 2896, 4096 and 8192. The authors believe that these were due to acoustic trauma. Many patients with appreciable high-tone loss gave a history of shell bursts nearby. The 15 patients examined before streptomycin therapy showed similar high-tone losses. Caloric tests after streptomycin therapy revealed a normal response in 65 patients. There was delay in one or both sides in 13 patients. Three patients showed absence of nystagmus after irrigation for five minutes with ice water. Two of these had a persistently negative and one a persistently positive Romberg sign. Two of these patients later showed recovery of the vestibular response.

### *Vertigo*

McNally<sup>10</sup> defines vertigo as a consciousness of discord in the postural mechanism. The maintenance of this mechanism is the main function of the labyrinth. Vertigo may be ocular, central or labyrinthine in cause. These origins are differentiated by the history, description of the vertigo and associated signs and symptoms. In labyrinthine vertigo there may be evidence of disease of the cochlear mechanism, such as deafness and tinnitus. Positional nystagmus may be present. Nystagmus is normally associated with labyrinthine stimulation. In some cases spontaneous nystagmus may occur only when the head is in a certain position. This type of nystagmus is known as positional, and the utricle is probably responsible for it. The presence of positional nystagmus aids in diagnosing pseudo-Ménière's disease. After removal of a cerebral hemisphere in a rabbit, any labyrinthine stimulation that produced a nystagmus toward the side of the brain lesion elicited a greater reaction than a stimulus that produced a nystagmus in the opposite direction. This phenomenon is called directional preponderance and may be of utricular origin. It has been said to occur only in temporal-lobe lesions, in man. The utricle may be concerned in reflex adaptation of posture to the field of gravity. Its function, however, cannot be the steady holding of posture. It helps to break up an existing postural debt and to impose a physiologically more suitable one.

According to Lindsay,<sup>11</sup> vertigo arising from disease of the central nervous system, such as encephalitis, abscess, tumor or multiple sclerosis, is the result of direct involvement of the vestibular nuclei or pathways or of pressure. The vertigo following head injury with concussion is probably central in origin if unaccompanied by auditory disturbance. As a toxic manifestation in the course of some respiratory and gastrointestinal infections, vertigo occurs frequently but without deafness or

tinnitus. It may also occur in cerebral arteriosclerosis and hypertension, as well as in hypotension and during the menopause. The localization is indefinite, but the absence of auditory symptoms suggests that it is central, and the pathologic disturbance is mild and reversible. When deafness and tinnitus occur with vertigo the lesion can be localized in the peripheral labyrinth or eighth nerve. In the past the most frequent cause has been a labyrinthitis from the extension of meningitis or inflammatory disease in the temporal bone. A disturbance of the peripheral labyrinth may occur from several other causes, such as nonsuppurative otitis media, virus diseases and, rarely, extrinsic allergy. The sudden onset of tinnitus, deafness and vertigo in a patient with a previously healthy ear leaves a profound and permanent impairment of function. Should this occur in middle life or later it is considered to be due to a vascular accident in the labyrinth. Similar episodes sometimes occur before middle age, and it may be impossible to differentiate these from an acute toxic process. A toxic disturbance affects auditory function primarily. However, it may not impair vestibular function. Precise pathological information in this type of labyrinthine lesion is not available. A fibroserous labyrinthitis may occur in the late stages of leukemia and is thought to be the result of hemorrhage in the labyrinth. The clinical condition known as Ménière's disease, which is characterized by recurring attacks of vertigo with fluctuating tinnitus and deafness, is now known to be associated with hydrops of the labyrinth. This type of hydrops is distinguishable from that which sometimes occurs in inflammatory disease of the inner ear, since in the former there are no inflammatory changes in the perilymphatic spaces and degeneration of the peripheral cochlear neuron is usually absent. The etiology is not known.

### *Ménière's Disease*

Cawthorne<sup>12</sup> reported a study on a series of 424 patients with Ménière's disease. Excluded were all patients who gave a history of otitis media or in whom an inflammatory process within the labyrinth was suspected, those in whom attacks were induced by sudden head movements, those with dizziness due to cardiovascular disease and those with anxiety neuroses. The general picture of the disease followed the usual pattern of periodic bouts of paroxysmal vertigo accompanied by nausea and vomiting. Some degree of nerve deafness with tinnitus was present and was always more noticeable on one side. No other signs of central-nervous-system disease were evident. The attacks varied greatly in all respects even in the same patient. The attacks tended to occur in groups, usually several within a short period followed by long intervals of freedom. Physical activity did not appear to influence the onset. Many attacks occurred at

procedure. Repeated treatment with external roentgen or radon seeds is effective and leaves only a small residual thickening or some superfluous tissue which may be excised later. Dermoid cysts occurred about the orbit, the floor of the mouth and the nose, in that order of frequency. In the floor of the mouth the cyst may be located above or below the myelohyoid muscle and tends to be spherical. The wall is thick, and where it can be readily palpated, the cyst has a doughy feel. Complete surgical removal is advisable. Thyroglossal cysts are lined by stratified or ciliated epithelium. Treatment consists of the removal of the cyst or cystic tract in the interval between infections. Branchial cysts may be present in the lateral aspect of the pharynx in the region of the posterior pillar, below the tonsils and in the hypopharynx at the base of the tongue. The cyst opening may be further enlarged when suspension laryngoscopy is used and the cystic tract can be destroyed with surgical diathermy using a protected point.

## LARYNX

### Laryngotracheitis

From 1926 to and including the months of January and February, 1945, 549 patients with laryngotracheobronchitis were admitted to the Hospital for Sick Children Toronto.<sup>19</sup> Over these years a steady increase in the number of admissions of patients with this disease was noted and the seriousness of the illness in individual patients was in inverse proportion to the number admitted in any year. In 1928, of 8 children admitted 6 died (a mortality of 75 per cent), whereas in 1944 the mortality was 9.2 per cent for 55 cases. The disease was particularly prevalent in children under the age of two years, 69 per cent of the patients being in this age group, whereas only 5 per cent were over six years of age. Over 70 per cent of the patients were admitted from November to April, the peak months were February and March. Organisms most frequently encountered were *Streptococcus haemolyticus*, *Staphylococcus aureus* and the pneumococcus, *Haemophilus influenzae* was seldom found. Many of the infections apparently were primarily due to a virus, and recognition of this was made by the lack of response to antibiotics, normal leukocyte count or leukopenia failure to grow pathogenic bacteria from culture material taken from the site of the disease and a fairly typical clinical course. Superficial destruction of the mucosa was noted most often in *Staph aureus* and *Sir haemolyticus* infections, and pseudomembranous inflammation was found most commonly in *Staph aureus* infections. Regarding prophylaxis, it was the opinion of these authors that antibiotics should be used in every case of simple croup for if they are given early enough the serious manifestations of bacterial infection will be prevented. If patients have virus infection the antibiotics will have little

curative effect, but secondary infection is prevented and the incidence of serious postoperative complications reduced. Early tracheotomy is the operation of choice and intubation is recommended only as a temporary expedient to relieve obstruction. Bronchoscopic removal of secretion is frequently resorted to. The principal causes of death are failure to relieve obstruction, overwhelming toxemia, postoperative infection, pneumothorax and mediastinal emphysema. The mortality has been gradually reduced for the past twenty years. This has been most striking in the tracheotomized patients, in whom a reduction in mortality from 80 to 55 per cent was accomplished.

### Inflamed Laryngitis

In children laryngeal infection caused by *H. influenzae* (Type B)<sup>21</sup> is rapidly progressive, and unless the disease is properly recognized and properly treated death from toxemia and asphyxiation results. The clinical features of this rapidly developing infection are characterized by an abrupt onset. The child becomes fretful and if old enough, complains of a sore throat and difficulty in swallowing. Respiratory distress with inspiratory retraction of the sternum and soft tissues, cyanosis, hoarseness and a croupy cough develop in extremely rapid progression. Patients are frequently limp and in shock, as shown by their ashen pallor. Children particularly those under the age of two are sometimes moribund within eight to twelve hours of onset. The temperature ranges from 100 to 104°F. The oropharynx is usually intensely red and edematous. Characteristically, the epiglottis and glottis are swollen and fiery red. No membrane is present, but exudate may or may not be present. The white-cell count is elevated to 15 000 or more with the differential count showing 80 or 90 per cent neutrophils. The diagnosis can be confirmed by the recovery of *H. influenzae* (Type B) in cultures from the nasopharynx, oropharynx, larynx, or blood. Catarrhal laryngitis and spasmodic croup present little difficulty in differential diagnosis since in neither condition is the toxicity so marked, the respiratory embarrassment so severe, or the symptoms so rapidly progressive. Although diphtheria and *H. influenzae* (Type B) laryngitis may resemble each other in their later stages, the onset is more insidious in diphtheria than in the former, and a typical membrane is usually present in the oropharynx or larynx from which diphtheria bacilli can be cultured. The three cardinal therapeutic measures in this type of laryngitis are tracheotomy for relief of respiratory obstruction, administration of sulfadiazine and Type B *H. influenzae* rabbit antiserum — both specific agents against this organism, and given together, more effective than either alone and parenteral administration of fluids to combat or prevent shock. There should be no hesitancy in performing trache-

from the ear contained many eosinophils. This group was classified as eosinophilic chronic otitis media. The other patients were classified as of the aneosinophilic type. The macroscopic appearance of the mucosa of the middle ear was strikingly different in the two types. It was slightly or moderately swollen in the aneosinophilic cases. In eosinophilic chronic otitis media on the other hand, the mucous membrane was always edematous and usually pale, with cyanotic areas similar in appearance to the mucous membrane of the nose in vasomotor rhinitis. The secretion was so viscid that often it had to be removed with forceps. Histologically the mucous membrane of the ear in the aneosinophilic cases showed chronic inflammation with round-cell infiltration dominated by lymphocytes and plasma cells. In the eosinophilic group the secretion showed clumps of eosinophilic leukocytes when stained and examined under the microscope. In the aneosinophilic group the microscopical picture of the secretion was wholly dominated by neutrophilic leukocytes interspersed with lymphocytes and monocytes. Healing of the ear was considerably longer in patients with eosinophilic otitis media, and associated allergic nasal symptoms were also more frequent in these patients. Bacteriologic investigation showed that the staphylococci were the commonest organisms in both eosinophilic and aneosinophilic otitis. *Proteus vulgaris* and coliform bacteria were especially common in aneosinophilic otitis. Twenty-seven patients with eosinophilic otitis were successfully treated by elimination of suspected allergins or desensitization, or both.

### SINUSES

#### Frontal Sinus

In acute fulminating frontal sinusitis early trephining is important to prevent extension of infection beyond the confines of the sinus. Good-year<sup>16</sup> uses a curved incision below the eyebrow and after incision of the periosteum an opening is made in the bone with a nail trephine almost at right angles to the sagittal plane of the nose, medial to the suprafrontal notch and just posterior to the medial orbital ridge. The cavity may be irrigated with warm saline solution to which penicillin has been added. A drain may be placed in the wound and removed in forty-eight hours. In acute frontal sinusitis when the size of the nasal chamber permits, the anterior ethmoid cells are opened, and those around the frontal ostium removed. The curet then enters the frontal sinus and allows evacuation of pus. This intranasal approach may also be used in chronic frontal-sinus infection. The depth and width of the affected sinus, as shown by roentgenograms, are important in deciding on the intranasal approach. When failure has occurred an external procedure becomes necessary. The Jansen-Lynch operation with the

use of a self-retaining gold tube is advised in all osteomas of the frontoethmoid area when suppuration is present. This tube may be left in place for life.

#### Subdural Empyema

Subdural empyema<sup>17</sup> may follow the initial attack of frontal sinusitis, or it may occur during an acute exacerbation of chronic frontal-sinus disease. In most cases infection is probably conveyed by way of perforating veins that extend from the frontal-sinus mucosa to the dura. The course of the disease is frequently short, and the period of survival may be only a few days. Headache, stiff neck, somnolence, Jacksonian convulsions and hemiparesis in a patient with frontal-sinus disease strongly suggest subdural abscess. Drainage is best accomplished through enlarged burr holes in the frontal, parietal and temporal regions, so arranged that thorough irrigation of the subdural cavity can be carried out. Drains are maintained in the subdural space for four to six days after operation. Death occurred in two of three patients with subdural infection secondary to frontal sinusitis within two weeks of the onset of cerebral symptoms, despite the use of antibiotics and supportive measures. The third patient recovered completely after early drainage.

### MOUTH AND PHARYNX

#### Congenital Cysts

According to New,<sup>18</sup> congenital cysts of the tongue, floor of the mouth, pharynx and larynx are rare and are difficult to diagnose and to remove completely. Repeated exacerbations due to infection may occur, and at such a time the cyst may rupture. After the discharge of the cyst contents, little can be found to account for the patient's symptoms. Uninfected cysts may cause no other symptoms than those due to increase in size. Ranula should designate only the thin-walled, epithelium-lined cyst, which is sometimes of a bluish tinge, fluctuates but does not pit on pressure and is soft and easily compressible. The cysts may be present at birth or may appear shortly afterward. Unless interference with breathing or eating is produced, immediate removal is not necessary. Complete surgical removal is the treatment of choice. Larger cysts may be treated by incision and destruction of the lining membrane with superficial surgical diathermy.

Cystic hygroma is a multilocular cyst usually found in the floor of the mouth or in the submental or submaxillary region. It is thin walled, has an endothelial lining and is usually filled with clear lymph. It is caused by obstruction or lack of development of afferent lymph vessels. Microscopically, cystic hygroma and lymphangioma cannot be distinguished, and the reaction of each to radium therapy is identical. Surgical removal is satisfactory if the patient can stand the operative

of age and 65 per cent were more than sixty-nine years of age. Of patients who were operated on and who could be traced, 73.5 per cent survived five or more years without recurrence of the growth. Of the laryngectomized patients, 60.2 per cent lived five or more years after operation. Of the patients who underwent thyrotomy, 83.6 per cent lived five or more years after operation. Of the patients treated by surgical diathermy or the insertion of radon seeds under suspension laryngoscopy, 91.7 per cent lived five or more years after operation. Of the patients who were treated by irradiation, 69 per cent lived five or more years after operation, 46 per cent of these patients underwent preliminary tracheotomy. The lower survival rate associated with laryngectomy is to be expected because all malignant lesions treated by this method were large, some had extralaryngeal extensions at the time of operation and some eventually showed metastases. The high rate of survival of patients treated by diathermy or the implantation of radon seeds under suspension laryngoscopy can be attributed to the facts that these patients were selected carefully and that the lesions were of low grade. The low survival rate of patients treated by irradiation is to be expected, since practically all the patients had inoperable lesions, the majority of which were considered completely hopeless when the patient was first examined.

otomy in children showing respiratory obstruction due to laryngeal edema with associated cyanosis and toxicity. Death results from a combination of mechanical obstruction to respiration and shock caused by the overwhelming infection, in addition to the anoxia produced by the respiratory obstruction.

### *Tracheotomy in Bulbar Poliomyelitis*

Tracheotomy is a useful and often life-saving procedure in bulbar poliomyelitis.<sup>21</sup> In the epidemic in Minneapolis in 1946, 400 patients had the bulbar type of poliomyelitis. In this group tracheotomy was performed on 75 patients, of whom 29 survived. On the adult neurologic service at the University of Minnesota Hospital tracheotomy was performed on all patients with early bulbar symptoms, when the disease was progressing rapidly, when the respiratory or circulatory centers were involved or when severe toxic or mental changes were noted. At the Minneapolis General Hospital and the University Hospital Pediatric Service tracheotomy was performed on the following indications: respiratory distress as evidenced by recurrent cyanosis, coarse rales in the chest and laryngeal stridor, excitement and unmanageability causing the patient to resist pharyngeal aspiration, stupor sufficient to make the patient oblivious of the accumulation of secretions in his airway, inability to cough effectively, pharyngeal pooling of mucus, and vocal-cord paralysis or intralaryngeal hypesthesia demonstrable by laryngoscopy.

Tracheotomy gives the best chance for survival when performed before cyanosis occurs. Cyanosis can be detected clinically only when far advanced, by which time anoxia has done irreversible damage to a central nervous system already markedly damaged by the virus. Combativeness, confusion, disorientation, irrationality and coma can be symptoms of early anoxia as well as of polioencephalitis. Failure to recognize the cause of these symptoms may misdirect therapy. The use of a respirator in the presence of both bulbar and spinal-cord lesions may suck the pharyngeal secretions into the lower respiratory tract. Tracheotomy permits aspiration of this secretion from the trachea and bronchi. Sedatives must be used with great caution. Priest et al.<sup>21</sup> felt that tracheotomy has an important place in the treatment of bulbar poliomyelitis and cited 17 cases in which the operation was believed to be the vital factor in successful treatment.

### *Stenosis*

In a series of 42 patients treated by Figg<sup>22</sup> for cicatricial stenosis of the larynx, fracture of the cartilages and previous removal of tumors were the most frequent causes of the stenosis. Less frequent causes were acute infection, self-inflicted and accidental severing of the trachea and the use

of the nasal feeding tubes. In 27 patients the stenosis was treated by opening of the larynx and, when necessary, the trachea and by excision of the scar tissue. A core of air-foam sponge rubber covered with a moderately thin skin graft removed from a nonhair-bearing area was then placed in the larynx or trachea and immobilized by transfixing with two silver alloy wires threaded on a long needle and passed directly through the skin, underlying soft tissues and thyroid cartilage, or between the tracheal rings. The rubber mold was removed at the end of ten days. Usually, the grafts took perfectly. Subsequent dilatation depended on how much cartilage was destroyed by the process that primarily induced the stenosis. If there was no appreciable destruction of cartilage and the stenosing scar was completely excised before the skin graft was applied, dilatation as a rule was not required for more than two or three weeks at most. Return of vocal function depends on the extent of loss of soft tissue and is unpredictable. When extensive destruction has occurred and the vocal cords, ventricular bands and arytenoid cartilages are not recognizable, the likelihood of restoration of voice is remote and the advisability of an attempt at surgical correction questionable. If the sphincteric action of the superior laryngeal orifice is lost, postoperative difficulty is encountered because of the tendency for food and fluid to gravitate into the trachea and lungs. In a patient with this condition after operation it became necessary to reproduce the stenosis because of difficulty in eating and drinking. Of the 27 patients treated by skin grafting, 24 had an ample lumen after operation and subsequent dilatation, and in 22 of these the tracheotomy opening has been closed. Of 10 patients treated by continuous dilatation and incision of the scar, decannulation was carried out in 8, who were free from symptoms at the time of the report. The remaining 2 still require a tracheotomy opening. Two patients treated by repeated incision of a cicatricial diaphragm without continuous dilatation had, at the time of the report, a free airway.

### *Carcinoma*

From the Mayo Clinic<sup>23</sup> a series of 568 patients treated for carcinoma of the larynx from 1934 to 1943, inclusive, was reported. Four hundred and forty-six of these were treated by surgical measures, and 122 were treated by irradiation. Of those patients who underwent operation, 213 were treated by laryngectomy, 184 by thyrotomy, and 49 by suspension laryngoscopy in which surgical diathermy was employed to destroy the growth or in which radon seeds were inserted into the growth. Of the 446 patients who underwent operation, 90.4 per cent were male and 9.6 per cent were female, 80.9 per cent were between the ages of forty-five and sixty-nine years, 12.6 per cent were less than four years

for better understanding and the promotion of world peace.

The House of Delegates also received reports on and discussed the correlation and extension of voluntary prepayment medical care plans, streamlining the procedure of the House, revision of the constitution and by-laws, increasing the Fellowship dues and subscription to the *Journal* to \$12.00 annually, creation of several new sections in the scientific body, approval of the Red Cross blood program, improvement of rural medical service and other matters relating to medical care.

The annual session of the Association will be held in Chicago later this month. Your delegate expects to be present, and will be pleased to bring before the House anything that the House of Delegates may wish presented there.

Dr Sycamore moved that the report of the Delegate to the American Medical Association be accepted.

This motion was duly seconded and was carried.

The report of the Committee on Medical Education and Hospitals was then presented, as follows:

The Speakers' Bureau has been somewhat rejuvenated since the resumption of more normal programs after the war. The membership of the Society was circularized last fall, and twenty-seven men indicated their willingness to be so listed. These lists are being classified by fields and sent to county-society secretaries.

The American Medical Association is now entering this activity with particular emphasis on speakers for lay audiences, and state and national lists will be combined for this purpose. The American Medical Association will keep the Chairman of the Committee informed whenever some prominent figure of the national association might be in this section, so that his services can be made available if desired. In this connection it might be advisable for county-society secretaries to inform the Chairman of the Committee whenever special speakers for lay audiences are sought.

The Hill-Burton Act, providing federal aid for hospital construction, is to operate in connection with the hospital plan of each state as approved by the United States Public Health Service. The New Hampshire plan has now been approved and will soon start operation, the first year of which will have terminated on June 30, 1949. This situation was rather thoroughly covered in the last annual report of the Committee.

The one urgent matter at this time is the enlisting of the active support of the officers of the Society in stimulating the interest of our membership in the New England Postgraduate Medical Assembly. A tremendous amount of work has been done by the Massachusetts membership of its Executive Committee, and the financial risk—a real one in the early days—was entirely assumed by the Massachusetts Medical Society.

The New Hampshire Medical Society, like several other state societies in this region, is not of sufficient membership or financial resources to conduct a state postgraduate assembly of its own. The New England Postgraduate Assembly is a logical solution. It has been a progressively successful venture—last year a splendid program was presented most efficiently—with excellent speakers and a wide range of subjects over the field of the general practice of medicine. Of the 591 members of the New Hampshire Medical Society, less than 30 registered at the Assembly last year. This is a rather pitiful participation from the standpoint of evidence of interest, when it is recollected that 65 per cent of our members are within two hours of Boston. This Committee doubts the extent of its function in stimulating a more real interest in New Hampshire registrations at the Assembly but suggests that the senior officers of the Society bring the matter before one of the general sessions at the annual meeting.

JOHN P. BOWLER, *Chairman*  
JAMES W. JAMESON  
SAMUEL M. BROOKS

Dr Sycamore moved that the Committee on Scientific Work be instructed to recommend procedures for stimulating the interest of the members of the New Hampshire Medical Society in the New England Postgraduate Assembly, and that the Secretary be instructed to carry out such recommendations as may be feasible.

This motion was duly seconded and was carried.

Dr Dye then stated that Dr Parker had requested that the Committee on Industrial Health be made twelve members instead of three. It was necessary that the recommendation be brought before the meeting, to amend the by-laws, and that this matter be laid on the table for one day.

This motion was duly seconded and was carried.

Dr Dye then moved that the meeting be adjourned until the following morning at nine o'clock.

This motion was duly seconded and was carried.

Whereupon, the first meeting of the House of Delegates was adjourned at 10:45 p.m.

The House of Delegates reconvened at Wentworth-by-the-Sea, Newcastle, on June 2, 1948, at 9:00 a.m., with Speaker McIlvor presiding.

The President, *ex-officio*

The Vice-President, *ex-officio*

The Secretary-Treasurer, *ex-officio*

Nathan Brody, Laconia

Reginald F. DeWitt, Plymouth

W. J. Paul Dye, Wolfeboro

Francis J. C. Dube, Center Ossipee

Walter H. Lacey, Keene

Marjorie A. Parsons, Colebrook

Francis M. Appleton, Gorham

Leslie K. Sycamore, Hanover

Leslie E. McKinlay, North Haverhill

Everett C. Campbell, Woodsville

Reginald K. House, Hanover

Joseph N. Friberg, Manchester

Norman W. Crisp, Nashua

Claire G. Cayward, New Ipswich

Daniel J. Sullivan, Nashua

Andrew L. MacMillan, Concord

Francis Brown Henniker

L. Whitaker, Portsmouth (alternate for John W. Blaisdell)

Donald W. Leonard, Exeter

Fred Fernald, Nottingham

A. E. Barcomb (alternate for Daniel F. McCooley)

Edna Walck, Dover

B. Read Lewin, Claremont

The speaker declared a quorum present and asked whether the members had any names to present for life memberships.

Dr MacMillan, for Merrimack County, presented the name of W. H. Mitchell.

Dr Walck, for Strafford County, presented the names of Anna C. Rudd, of Durham, and E. M. Abbott, of Rochester.

The Secretary, when it had been explained that Dr Abbott had not been a member for a continuous fifteen years, stated that the by-laws would have to be amended to authorize life membership for him.

Dr Parsons suggested that, since Dr Abbott was disabled, the by-laws be changed so that anyone who is totally disabled would be eligible.

Dr Dye observed that such a change could be laid on the table and voted on the following day.

## NEW HAMPSHIRE MEDICAL SOCIETY

### PROCEEDINGS OF THE ONE HUNDRED AND FIFTY-SEVENTH ANNIVERSARY

House of Delegates, June 1, 2 and 3, 1948 (Concluded)

The report of the Committee on Public Health was presented

The Committee devoted its attention during the past year to the proper public-health coverage for the State

It is evident through the casual perusal of town reports that the matter of public health receives little or no attention. The smaller towns appropriate five or ten dollars a year as salary for their public-health officials, and expect them to make all sanitary inspections, to correct unsanitary conditions satisfactorily and to post cases of communicable disease. Often, they select as health officer one who has no training whatsoever, and because of the low salary or pay offered, he performs his duties reluctantly, unsatisfactorily and haphazardly. In some towns the physician serves as the community health officer, but has only the time to list the communicable diseases required by law. Even in the larger towns and cities, the health departments, if they can be called such, are undermanned, and an adequate public-health program is not possible.

In some cities more money is expended for the care of cemeteries and for parks and trees than for the health departments. One city, for example, expended \$7000 for the health of its people, \$17,000 for parks and shade trees, and \$39,000 for the care of the dead.

The counties have no health setup whatsoever, and the maintenance of public-health standards for the State resolves in most part upon the State health department. It is generally conceded that with the staff available, the State health department does an excellent job. It is also generally conceded that only the surface can be scratched so far as the entire State is concerned. A much more extensive health organization is needed adequately to protect the health of the people, as well as to educate them in public-health matters. The small beginning made by the Dental Division of the State Department of Health is to be commended.

There are two solutions to the problem at hand. The first is to improve the qualifications of the local health officials, but this seems an impossible task inasmuch as the pay involved is insufficient. The second solution, and by far the more feasible one, is the establishment by the State Department of Health, through proper legislation and adequate appropriations, of regional headquarters by county lines or by geographic areas, so that all the State may be adequately covered.

The opposition to this organization is twofold. The first is the reduction of authority of the towns, and the second the increase of the burden of the taxpayers. It seems that the same situation is present in this case as in that of the State Police, whose duty it is to safeguard the people of the State, in conjunction with local authorities.

The additional expense of this expansion would in part be borne by the federal Government, which would partially offset the budget increases. One such subdivision has been operated in the Exeter area for the past six years, and the results have been gratifying.

This state-wide organization meets the approval of health authorities, and it would mean no radical change in the setup of the State Department of Health.

The immediate expansion of the regional headquarters does not require expensive personnel, and in some areas not even a medical director would be necessary. Properly trained sanitary inspectors, and possibly a sanitary engineer, could adequately run the work for the present.

State nurses, who are now located in various sections, would therefore have local headquarters in place of makeshift ones, which are now used in some areas. These headquarters would serve as local distribution centers for serums, laboratory supplies, public-health literature and

other health information. They not only would expedite the work of the Health Department but also would definitely decrease health hazards, and improve the general health of the communities. An active educational program could be adequately promulgated through societies, schools and special courses.

It is the belief of the Committee that active steps should be taken by the New Hampshire Medical Society to foster this program in the next legislative session. It will be necessary to show clearly and concisely to the various members of the legislature that such a need is evident, and that the increased appropriations for its development will be money well invested with handsome returns in the form of better health to all the people of the State. It is suggested that the Committee on Public Health be given instructions, that the health expansion program may become actual in due time.

DONALD G. BARTON, Chairman  
HARRY W. SAVAGE  
HERMANN N. SANDER

Dr. Sycamore, for the Committee on Officers' Reports, moved that the Society go on record as deploring the inadequacy of public-health measures throughout the state, and that the Committee on Public Health be authorized to appear before the Legislature to present the needs in this field.

This motion was duly seconded and was carried.

Dr. Deering G. Smith, delegate to the American Medical Association, presented the following report:

The first interim session of the American Medical Association was held in Cleveland in January. This included the meeting of the House of Delegates, and a scientific program for general practitioners, which was attended by over 3000 enthusiastic physicians.

Your delegate served as chairman of the Reference Committee on Reports of Officers, and later was appointed a member of an interim committee to study the question of intern placements. Many more internships are available than there are physicians desiring them, which makes their distribution a serious problem to many hospitals. Others matters being studied by special committees are the nursing situation and the practice of medicine by hospitals.

The importance of the general practitioner was stressed in the "Grass Roots Conference," where his problems were discussed, and by the presentation of the General Practitioner's Award, for rendering exceptional service to his community, to Dr. Archer C. Sudan, of Colorado.

The question of what the American Medical Association is doing to improve medical care and to combat state medicine is often heard. The answer is given in an excellent report of the Board of Trustees, showing the progress that has been made toward the accomplishment of the objectives of the "Ten Point National Health Program of the American Medical Association." This report is printed on pages 261-266 of the *Journal of the American Medical Association* of January 24, 1948, and is worthy of attention.

The Council on National Emergency Medical Service has become active, and it is hoped that with the co-operation of the federal authorities and the various state committees like our own, definite plans may be made for handling emergencies.

A report was given concerning the formation of the world medical association. Forty-eight nations are represented in the association, which is indirectly a medium.

It is planned for the coming year that the Committee will prepare and distribute informative literature relative to industrial health problems. This material will be prepared in co-operation with the Division of Industrial Hygiene, State Health Department, and the Committee on Industrial Health, New Hampshire Manufacturers' Association

DAVID W PARKER, *Chairman*

Dr Sycamore moved that the recommendations of the Committee on Industrial Health be approved

This motion was duly seconded and was carried

Dr Dye stated that on the previous night it had been voted to amend the by-laws to change the membership of the Committee on Industrial Health from three to twelve members. It was laid on the table until this morning. He therefore, moved that the by-laws be changed to read "twelve members"

This motion was duly seconded and was carried

President Hunter then stated that he had had a letter from Dr Howard B Sprague, of Boston, asking if the New Hampshire Medical Society would contribute money for the New England Branch of the American Heart Association. He had replied that of course, nothing could be done, until this meeting of the House of Delegates

The Speaker asked for discussion on this matter

Dr Dye replied that he considered the project worth while but doubted whether the Society could afford to establish a precedent of giving contributions to different worthy causes. Therefore, he moved that the Secretary write to Dr Sprague and say that the Society is heartily in sympathy with the American Heart Association cause and will do anything that it can in the way of individual contributions to help out but that as a State Society it had a precedent of not making contributions

This motion was duly seconded and was carried

The Secretary suggested that the President answer the letter of Dr Sprague

Dr Brown then observed that Merrimack County Society had voted at its last meeting to assume the responsibility for a hospital bill of a former member of the Society who was in financial straits, he asked whether there was any fund to take care of anything like this, such as reimbursing the county society

Dr MacMillan stated that Merrimack County was not agreed regarding this matter, he had been asked to present the same question, and his opinion was that such a step was ill advised

The Speaker remarked that he agreed with Dr MacMillan

The second meeting of the House of Delegates adjourned at 9 45 a m

The House of Delegates reconvened at Wentworth-by-the-Sea, Newcastle, on June 3, 1948, at 9 15 a m, with Vice-Speaker Dube presiding

The following members answered the roll call

- Nathan Brody, Laconia
- W J Paul Dye, Wolfeboro
- Francis J C Dube, Center Ossipee
- Walter H Lacey, Keene (alternate)
- Marjorie A Parsons, Colebrook
- Francis M Appleton, Gorham
- Leslie K Sycamore, Hanover
- Reginald K House, Hanover
- Joseph N Friborg, Manchester
- Andrew L MacMillan, Concord
- Francis Brown, Henniker
- Fred Fernald, Nottingham
- A E Barcomb (alternate)
- B Read Lewin, Claremont

The Speaker declared a quorum present

President Hunter nominated Dr George C Wilkins and Dr George Dwinell in place of the delegates from Hillsborough County not present

The Committee on Nominations presented its report, and the balloting took place for the office of president and vice-president, as follows

PRESIDENT

Clarence E Dunbar, M D, of Manchester

VICE-PRESIDENT

John P Bowler, M D, of Hanover

COUNCILOR FOR BELKNAP COUNTY FOR FIVE YEARS

Chester L Smart, M D, of Laconia

COUNCILOR FOR GRAFTON COUNTY FOR FIVE YEARS

Arthur W Burnham, M D, of Lebanon

TRUSTEE FOR TWO YEARS

James W Jameson, M D, of Concord

TRUSTEE FOR THREE YEARS

George C Wilkins, M D, of Manchester

SPEAKER OF THE HOUSE OF DELEGATES

Francis J C Dube, M D, of Center Ossipee

VICE-SPEAKER OF THE HOUSE OF DELEGATES

B Read Lewin, M D, of Claremont

NECROLOGIST

Ralph W Tuttle, M D, of Wolfeboro

DELEGATE TO THE AMERICAN MEDICAL ASSOCIATION FOR 1948-50

Deering G Smith, M D, of Nashua

ALTERNATE DELEGATE TO THE AMERICAN MEDICAL ASSOCIATION FOR 1948-50

Howard P Sawyer, M D, of Brookfield

STANDING COMMITTEES

*Advisory Committee on Jurisprudence* Chester L Smart, Belknap County, W J Paul Dye, Carroll County, Robert W Holmes, Cheshire County, Arthur W Burnham, Grafton County, David W Parker, Hillsborough County, Robert J Graves, Merrimack County, Lawrence R Hazzard, Rockingham County, Jeremiah J Morin, Strafford County, B Read Lewin, Sullivan County, Carleton R Metcalf, Concord, *Chairman*

*Amendments to Constitution and By-Laws* W J Paul Dye, Wolfeboro, Loren F Richards, Nashua, Joseph E Larochelle, Berlin

*Child Health* Thomas B Walker, Portsmouth, Ursula G Sanders, Concord, Marion Fairfield, Nashua

*Control of Cancer* George C Wilkins, Manchester, Ralph E Miller, Hanover, George F Dwinell, Manchester, Walter H Lacey, Keene, Albert Oppenheimer, Laconia

*Council of New England Medical Societies* Carleton R Metcalf, Concord, Clarence E Dunbar, Manchester, Ralph W Tuttle, Wolfeboro

The President, *ex-officio*  
The Vice-President, *ex-officio*  
The Secretary-Treasurer *ex-officio*

Dr Brody moved that the word "continuous" be removed from the by-laws

Dr Friberg seconded the motion

The Speaker then requested all those in favor of amending Section 5 of the by-laws to read "Any physician who has been a member of this Society for fifteen years is eligible for life membership" to signify assent by raising the right hand

There were seventeen hands raised for the motion, and fourteen against the motion, which was declared to be carried

Dr Parsons, for Coos County, presented the names of John M Blodgett, R E Webb, Edward R B McGee, L B Marcou and A C Rondinella.

Dr Dye moved that all the names be accepted for life membership, except Dr Abbott, who would be voted upon on the following day

This motion was duly seconded and was carried

The Report of the Committee on Industrial Health was then presented, as follows

The Committee has not accomplished all it desired during the past year, but it is believed that the ground-work has been laid for greater effort in industrial medicine during the coming years

It is desired to point out at the beginning of this report that, among a large number of industrial officials in New Hampshire, and to a certain extent among the physicians, an apathy exists to industrial medical service. The importance of the problem of preventive medicine in industry received tremendous stimulus during the war, and today in practically every state, more and more emphasis and effort is being directed to meet these problems. Medical societies, nurses' groups, industrial organizations, Government health organizations, insurance companies and others are working together in an effort to reduce to a minimum, sickness and injuries that cause absenteeism from work and great economic losses to both the employer and the employees. It is a well known fact that the provision of good preventive medical programs, with adequate medical care of injuries and potential illnesses, will keep industrial absenteeism at a minimum.

New Hampshire is an industrial state and ranks fourth of all states in the percentage of workers gainfully employed in industrial plants. In 1938 the State Health Department conducted a survey of all plants for the purpose of determining health conditions in the plants, and the medical and nursing services provided for the employees.

The results of this survey showed that the health-service provisions available for workers were much lower than in other states and areas. Although this condition has improved to some extent during recent years, particularly in the number of nurses employed by plants, there is still a great need for improvement.

Early in the year a meeting of the Committee was held with the director of the Division of Industrial Hygiene, New Hampshire State Department of Health in Concord, at which objectives were drawn up that would enhance close co-operation of the New Hampshire Medical Society and the State Department of Health in the conduct of an industrial health program. The following objectives were unanimously approved at this meeting:

The Committee on Industrial Health, New Hampshire Medical Society, and the Division of Industrial Hygiene, New Hampshire State Department of Health, will work in close co-operation with each other. Policies, procedures and methods of the program will be discussed jointly by both organizations.

The Committee on Industrial Health approves the present health activities of the Division of Industrial Hygiene. These activities include engineering and chemical studies for the purpose of evaluating potential health hazards from dusts, gases, fumes, mists, vapors and other substances to which workers are exposed at the

various operations in industrial plants, investigations of reported occupational diseases for the purpose of assisting industry in the prevention of additional cases, the conduct of health evaluation surveys in small industrial plants, the study of the silicosis problem in view of prevention, and the promotion of health education among industrial workers.

The Committee voted to have the Chairman invite the New Hampshire Manufacturers Association to appoint a committee on industrial health, which would work in conjunction with our committee. This invitation was forwarded to the president of the New Hampshire Manufacturers Association, and a reply was received that such a committee would be appointed. After much delay notification was received on April 29, 1948, that a committee had been appointed. Members of this committee are Charles S Parsons, of the Chicopee Manufacturing Company, Manchester, Eustace Cummings, of E Cummings Leather Company, Incorporated, Lebanon and C Henry O'Neil, of the Nashua Gummed and Coated Paper Company, Nashua.

At this meeting, the following resolutions were adopted by the Committee and are submitted to the Society for its consideration and approval:

That the New Hampshire Medical Society urge all members to report known occupational diseases to the New Hampshire State Department of Health as provided under Chapter 132, Section 1-5, of the New Hampshire State Public Law. The reporting of these diseases is particularly important in view of the Workmen's Compensation Law as passed by the last legislature for the compensation of occupational diseases. It is understood by the Committee that no compensation will be paid for occupational diseases until official reports have been made by the attending physician.

That the Society include in its future scientific programs a symposium on industrial health, or invite a nationally known speaker to present a subject of interest to the general practitioners on industrial health. In view of the large variety of new chemicals and other substances being used in the industrial plants in New Hampshire, it is believed that the medical profession should be familiar with the toxicity and action of such materials to recognize early symptoms of absorption among industrial employees. The State Health Department has available a 70-mm mobile x-ray unit, and through the co-operation of the physicians and industrial officials, screening x-ray films can be made available to the industrial workers.

That the Society urge industry to make provisions for employing handicapped persons, provided that they are not hazardous to themselves and fellow employees, and are able to perform assigned duties satisfactorily.

That members of the Society co-operate with the Division of Industrial Hygiene, New Hampshire State Department of Health, in the conduct of health evaluation surveys among industrial employees.

These surveys consist essentially of an evaluation of the health of the employees in various types of industry in the State. The surveys include chest x-ray films, dental examinations, eye tests, hearing tests, examination of the urine for albumin and sugar and special tests if the employees are exposed to toxic materials. The results of these tests are entirely confidential between the individual employee, the employee's physician and the New Hampshire State Department of Health. If defects are found, the employee is requested to see his own physician for further study.

The Committee recommends that industrial plants employing 500 or more persons employ a full-time nurse with adequate industrial training, who will work under the supervision of a physician. Smaller plants should combine to employ a nurse who will divide her services between the individual plants. The physician and nurse should spend regular hours at the plant. In addition, the plants should provide medical dispensaries with adequate facilities and equipment.

For the activities and achievements of the committee to be increased, it is requested that the membership of the committee be increased to twelve members, to include physicians who are actively engaged in industrial medicine and who reside in the industrial cities of this State.

Dr Sycamore then observed that the matter of the telegram from the California Medical Association regarding Governor Warren had been referred to the Committee on Officers' Reports, which recommended the following resolution

*Whereas*, Governor Earl Warren of California has announced his candidacy for the Republican nomination for President of the United States, and

*Whereas*, Governor Warren has advocated a state system of compulsory sickness insurance in California and is alleged to advocate the inclusion in the Republican platform of a plank favoring national compulsory sickness insurance, and

*Whereas*, the New Hampshire Medical Society is opposed to any form of national compulsory sickness insurance,

*Therefore, be it resolved* That the New Hampshire Medical Society is opposed to the nomination of Governor Warren for either the Presidency or Vice-Presidency of the United States

*And be it further resolved* That the New Hampshire Medical Society is opposed to the inclusion in the Republican Platform of any plank favoring national compulsory sickness insurance,

*And be it further resolved* That a copy of this resolution be sent to the New Hampshire representatives in Congress and to the members of the New Hampshire delegation to the Republican National Convention

Dr Sycamore moved the adoption of this resolution

This motion was duly seconded and was carried  
The Secretary then spoke as follows

I am a little discouraged about our New Hampshire Society, which looks as if it were dying from old age. We have 160 people out for this meeting we had 222 last year, and ten years ago we used to draw 300. Whether it is the location of the meeting, the cost of the meeting or the program, I do not know, but the men do not come. It seems to me that we have got to put our finger on the sore spot, if we can, and see why our meetings do not attract more people.

This morning before the meeting, it was mentioned that we could have a meeting at Hanover, so that there could be some clinical cases to see. Dr Sycamore thought they could handle the crowd all right, there, after the middle of June. And, of course, we also spoke about going up into the mountains another year. I do not know whether we can settle on it this morning, if it cannot be settled here, it ought to be delegated to the officers or to somebody who could go over the situation. But, for one, I should certainly like to get any ideas on the subject that will buck the thing up.

Another suggestion that was made was to have a one-day meeting, similar to the meeting of the New Hampshire Surgical Club, and not try to stay overnight anywhere, and have it at some place like Manchester or Concord, and perhaps put on a clinical show in addition to the papers.

If any of you have any ideas on what is wrong with the New Hampshire Medical Society, I should like to hear them.

Dr George C Wilkins stated that if the meetings were held in Manchester or Concord, there would be a larger attendance, but, unfortunately, there were insufficient accommodations in both cities which was one of the reasons why Newcastle had been selected.

He believed that the meetings, when held at a summer hotel, kept away a certain number of people, on account of the expense involved. Another thing was the distance required to travel for a certain

number of people who live in the upper part of the State.

The Secretary observed that for several years, the afternoon programs had been made up of speakers from outside New Hampshire. However, this year, a good many New Hampshire men had been on for brief papers in the afternoon. This matter of the type of program preferred should be settled.

Dr Brody remarked that the largest concentration of medical men was apparently in Nashua, Manchester and Concord — probably close to 150 men — and that if the meetings could be held near those cities, the attendance might be better. He suggested a one-day meeting in one of those cities.

The Secretary replied that the meeting would then be similar to those of the New Hampshire Surgical Club meetings.

Dr Brown asked what the attendance was at those meetings.

The Secretary answered that during the war a great many of the men were away, and the meetings were rather poorly attended.

Dr Brown then asked what percentage of the people attending the meeting attended the scientific sessions.

The Secretary stated that 116 doctors had been registered on the previous day, he did not know how many were present at the afternoon session. He guessed that about half the members went to the scientific sessions.

Dr Dunbar stated that if the meetings were held near the center of the population, the problem of finding accommodations would come up. He suggested that arrangements be made at some of the overnight camps.

Dr MacMillan did not think that it would be wise to go back to the one-day meeting, which he considered to be the poorest meetings the Society had ever had. He suggested that the lack of attendance be overlooked and the meetings made as good as possible, so as to interest more members.

The Secretary asked whether the House of Delegates favored having New Hampshire men on the afternoon program or trying to get men from the urban centers outside the State.

Dr House believed that it was more stimulating to have men from outside the State. If somebody came in from outside, he might give the members a little something else to think about.

The Secretary replied that last year the obstetrician-in-chief at Johns Hopkins University School of Medicine had spoken to an audience of twenty-three.

The Speaker asked how many members were in favor of continuing the two-day sessions.

Almost all hands were raised.

He then asked how many were in favor of returning to Newcastle next year, late in June, when it would be warmer.

Nine delegates raised their hands.

*Industrial Health* David W Parker, Manchester, Henry Almond, Berlin, Robert J Graves, Concord, Charles F Keeley, Claremont, Robert W Holmes, Keene, John Samuel Wheeler, Concord, Daniel F McCooley, Dover, John C Eekels, Laconia, Robert Flanders, Manchester, John H Kennard, Manchester, Timothy Francis Roek, Nashua, Charles I Umpa, Nashua

*Maternity and Infancy* Robert O Blood, Concord, Benjamin P Burpee, Manchester, Frederick S Gray, Portsmouth

*Medical Economics* Leslie K Sycamore, Hanover, Francis J C Dube, Center Ossipee, Joseph N Friborg, Manchester

*Medical Education and Hospitals* John P Bowler, Hanover, James W Jameson, Concord, Howard P Sawyer, Brookfield

*Mental Hygiene* Arthur B Howard, Concord, Edward S Morris, Laconia, Simon Stone, Manchester

*National Emergency Medical Service* Daniel J Sullivan, Nashua, Joseph M McCarthy, Concord, Clarence E Dunbar, Manchester, Bernard J Manning, Dover, John C Eekels, Laconia

*Public Health* Donald G Barton, Concord, Harry W Savage, Lebanon, Hermann N Sander, Manchester

*Public Relations* Clarence E Dunbar, Manchester (president), John P Bowler, Hanover (vice-president), Carleton R Metcalf, Concord, (Secretary-Treasurer), Francis Brown, Henniker, Joseph N Friborg, Manchester

*Publications* Carleton R Metcalf, Concord, Samuel J King, Rochester, Lester R Whitaker, Portsmouth

*Rural Health* William F Putnam, Lyme, William P Clough, Jr, New London, Samuel Feiner, Ashland

*Scientific Work* Carleton R Metcalf, Concord, Robert R Rix, Manchester, Sven Gundersen, Hanover

*Tuberculosis* Robert B Kerr, Manchester, Frank G Seldon, Manchester, John D Spring, Nashua

Dr Dye then moved that the amendment to Section 5 of the by-laws, voted upon at the meeting of the previous day, be approved and that the Article concerning life membership be changed, striking out the word "continuous" on page 19, Section 5, Chapter I, so that the section would read

Any physician who has been a member of this Society for a term of fifteen years and is either not less than sixty-five years of age or totally disabled, on the request of his county society, may be made a life member by a majority of the votes of the House of Delegates. Life members shall have the same rights and privileges as other members of the Society, but shall not be required to pay dues

This motion was duly seconded and was carried by the majority required

Dr Sycamore then stated that the New Hampshire members of the Board of Physicians Service were subject to the approval of the House of Delegates, and he moved that these members be approved

This motion was duly seconded and was carried

The financial report of the Trustees was then presented, as follows

JANUARY 1-DECEMBER 31, 1947

#### GENERAL FUND

GEO C WILKINS

Audited and found correct, May 14, 1948

(Signed) DAVID C RENNIE, Auditor

Dr Sycamore then observed that the matter of the telegram from the California Medical Association regarding Governor Warren had been referred to the Committee on Officers' Reports, which recommended the following resolution

*Whereas*, Governor Earl Warren of California has announced his candidacy for the Republican nomination for President of the United States, and

*Whereas*, Governor Warren has advocated a state system of compulsory sickness insurance in California and is alleged to advocate the inclusion in the Republican platform of a plank favoring national compulsory sickness insurance, and

*Whereas*, the New Hampshire Medical Society is opposed to any form of national compulsory sickness insurance,

*Therefore, be it resolved* That the New Hampshire Medical Society is opposed to the nomination of Governor Warren for either the Presidency or Vice-Presidency of the United States

*And be it further resolved* That the New Hampshire Medical Society is opposed to the inclusion in the Republican Platform of any plank favoring national compulsory sickness insurance

*And be it further resolved* That a copy of this resolution be sent to the New Hampshire representatives in Congress and to the members of the New Hampshire delegation to the Republican National Convention

Dr Sycamore moved the adoption of this resolution

This motion was duly seconded and was carried  
The Secretary then spoke as follows

I am a little discouraged about our New Hampshire Society, which looks as if it were dying from old age. We have 160 people out for this meeting, we had 222 last year, and ten years ago we used to draw 300. Whether it is the location of the meeting, the cost of the meeting or the program, I do not know, but the men do not come. It seems to me that we have got to put our finger on the sore spot, if we can, and see why our meetings do not attract more people.

This morning before the meeting, it was mentioned that we could have a meeting at Hanover, so that there could be some clinical cases to see. Dr Sycamore thought they could handle the crowd all right, there, after the middle of June. And, of course, we also spoke about going up into the mountains another year. I do not know whether we can settle on it this morning, if it cannot be settled here, it ought to be delegated to the officers or to somebody who could go over the situation. But, for one, I should certainly like to get any ideas on the subject that will buck the thing up.

Another suggestion that was made was to have a one-day meeting, similar to the meeting of the New Hampshire Surgical Club, and not try to stay overnight anywhere, and have it at some place like Manchester or Concord, and perhaps put on a clinical show in addition to the papers.

If any of you have any ideas on what is wrong with the New Hampshire Medical Society, I should like to hear them.

Dr George C Wilkins stated that if the meetings were held in Manchester or Concord, there would be a larger attendance, but, unfortunately, there were insufficient accommodations in both cities which was one of the reasons why Newcastle had been selected.

He believed that the meetings, when held at a summer hotel, kept away a certain number of people, on account of the expense involved. Another thing was the distance required to travel for a certain

number of people who live in the upper part of the State.

The Secretary observed that for several years, the afternoon programs had been made up of speakers from outside New Hampshire. However, this year, a good many New Hampshire men had been on for brief papers in the afternoon. This matter of the type of program preferred should be settled.

Dr Brody remarked that the largest concentration of medical men was apparently in Nashua, Manchester and Concord — probably close to 150 men — and that if the meetings could be held near those cities, the attendance might be better. He suggested a one-day meeting in one of those cities.

The Secretary replied that the meeting would then be similar to those of the New Hampshire Surgical Club meetings.

Dr Brown asked what the attendance was at those meetings.

The Secretary answered that during the war a great many of the men were away, and the meetings were rather poorly attended.

Dr Brown then asked what percentage of the people attending the meeting attended the scientific sessions.

The Secretary stated that 116 doctors had been registered on the previous day, he did not know how many were present at the afternoon session. He guessed that about half the members went to the scientific sessions.

Dr Dunbar stated that if the meetings were held near the center of the population, the problem of finding accommodations would come up. He suggested that arrangements be made at some of the overnight camps.

Dr MacMillan did not think that it would be wise to go back to the one-day meeting, which he considered to be the poorest meetings the Society had ever had. He suggested that the lack of attendance be overlooked and the meetings made as good as possible, so as to interest more members.

The Secretary asked whether the House of Delegates favored having New Hampshire men on the afternoon program or trying to get men from the urban centers outside the State.

Dr House believed that it was more stimulating to have men from outside the State. If somebody came in from outside, he might give the members a little something else to think about.

The Secretary replied that last year, the obstetrician-in-chief at Johns Hopkins University School of Medicine had spoken to an audience of twenty-three.

The Speaker asked how many members were in favor of continuing the two-day sessions.

Almost all hands were raised.

He then asked how many were in favor of returning to Newcastle next year, late in June, when it would be warmer.

Nine delegates raised their hands.

In reply to the question how many were in favor of going somewhere else, several delegates raised hands, and to the question how many would be in favor of having during the afternoon sessions out-of-state speakers of international or national fame there was no response

Unanimous approval was expressed of the idea of having a program at the afternoon sessions with New Hampshire men, such as those at the present session, as well as out-of-state men

A member asked what the opinion was about using the first evening for papers, and leaving the afternoon free for enjoying golf or whatever the members wished to do

Fifteen delegates raised hands

The Speaker asked how many were in favor of having formal dress at the banquet

No hands were raised

The Secretary stated that the idea of using the first evening for scientific sessions was original but that some members might complain unless there was something for them to do in the afternoon

After further discussion Dr Sycamore moved that the time and place of the next meeting be left to the officers of the Society, taking into consideration the foregoing discussion

This motion was duly seconded and was carried

Dr Dye then moved that Dr Abbott, of Rochester, be made a life member

This motion was duly seconded and was carried

Dr Friberg moved that the Rockingham County Committee be thanked for the work in preparing the program

This motion was duly seconded and was carried

Speaker Dube then declared the meeting adjourned

Whereupon, the third meeting of the House of Delegates was adjourned at 10 15 a m

### CASE 34481

#### PRESENTATION OF CASE

A forty-one-year-old woman was admitted to the hospital from a chest clinic because of a lesion in the left chest

The patient was well until three months before admission, when she contracted an upper respiratory infection with coryza, hoarseness and a cough productive of half a cup of brownish-gray sputum a day. The cough and sputum production subsided, but hoarseness continued, and increasing dyspnea, rapid breathing, occasional "choking" spells and wheezing respiration followed. There had been a 15-pound weight loss in four months, despite an excellent appetite, and progressive weakness. The latter was intermittent, accompanied by profuse sweating and a feeling of imminent blackout. For three weeks she had soreness in the left chest. When she was eighteen, she had a spot on the right lung, which cleared after a year of bed rest. Eleven years before admission a right nephrostomy for renal cal-

culi was performed. Three years before entry a total hysterectomy and right salpingo-oophorectomy were performed at this hospital for vaginal bleeding. The pathological diagnosis was tubal pregnancy. Two years before entry a neighbor, with whom she had had contact, developed tuberculosis. For that reason a chest x-ray film was taken at that time. It was reported to be normal.

Physical examination revealed a woman who appeared chronically ill. The fingernails showed moderate clubbing. There were tenderness on pressure over the left chest, anteriorly and posteriorly, and dullness over the left base posteriorly, with decreased left diaphragmatic excursion.

The blood pressure was 140 systolic, 90 diastolic. Examination of the blood demonstrated a hemoglobin of 12.5 gm and a white-cell count of 8400. The urine specific gravity was 1.020, no albumin or significant formed elements were found. The non-protein nitrogen was 16 mg, and the total protein 7.5 gm per 100 cc.

X-ray examination of the chest demonstrated a well circumscribed area of increased density at the apex of the left lower lobe, measuring about 8 by 8 by 10 cm (Fig 1). There was no degeneration within it. The remainder of the lung parenchyma was clear. Intravenous and retrograde pyelography showed a deformity of the calyces and pelvis on the right, with dilatation of the superior and inferior calyces. The left kidney pelvis was normal. Both kidney shadows were of normal size.

A bronchoscopy demonstrated no abnormalities. A smear taken from the dorsal division of the left upper-lobe bronchus was negative for tumor cells. In smears taken from the left-lower-lobe bronchus a few acid-fast bacilli were found. Needle aspiration of the chest lesion was unsuccessful. During the first

ten hospital days the patient's course was not remarkable. She was afebrile. On the eleventh hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR MERRILL SOSMAN \* I think it is fair, inasmuch as the patient was admitted because of an x-ray finding from a chest clinic, to start with the films and then work back to the history, physical examination and laboratory findings.

We can see in this film that this is the chest of a young woman, "young" being comparative — any-

amination two years before admission following exposure to a patient with tuberculosis. If that is reliable, it certainly would rule out both the congenital group of tumors and the benign tumors. If it was a tumor, it would have had to be malignant to reach this size in two years. Do we know where the x-ray examination was done?

DR TRACY B MALLORY It was done in one of the state sanatoriums.

DR SOSMAN Then it should be reliable. One other thing that we should note in evaluating the shadow is whether or not it was movable with the

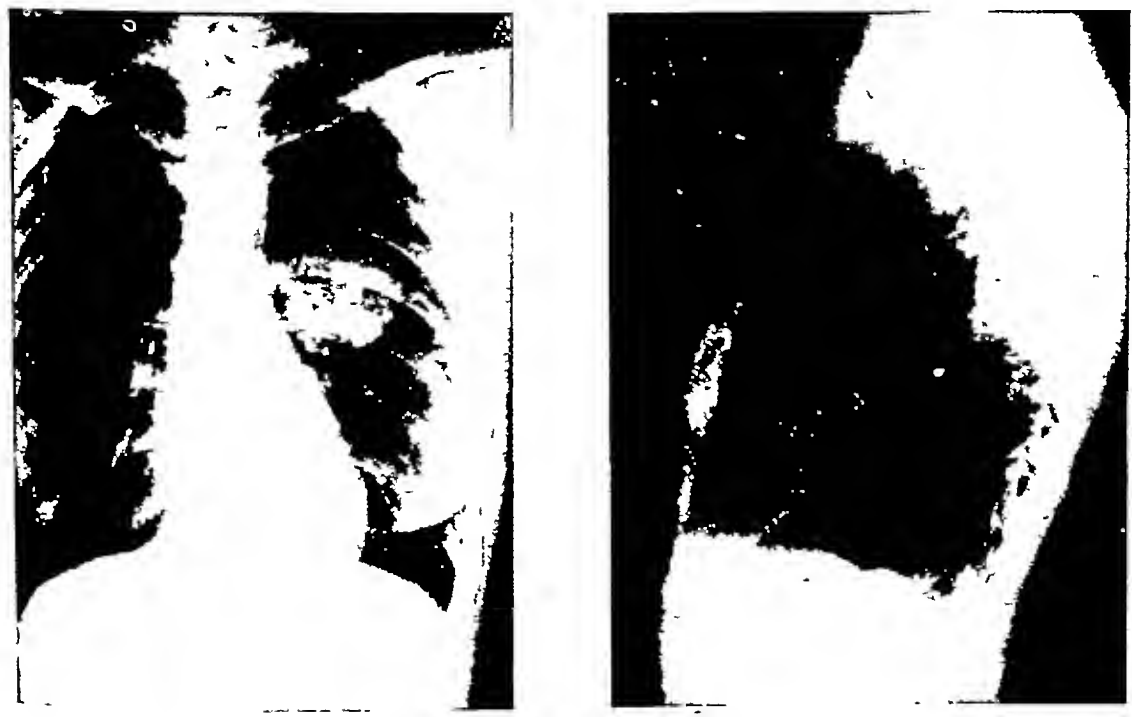

FIGURE 1

one below one's own age is young and anyone above it is old. She has a single lesion in the left midchest, measuring 8 cm in diameter and not very sharply outlined. In the lateral view, lying well back posteriorly in the chest, the shadow is shaped a good deal like a gumdrop, the flat part being against the posterior chest wall and the anterior surface being sharply rounded or convex. The other findings in the chest appear perfectly normal. The heart is not displaced, the diaphragm is in normal position, the ribs are intact. The trachea appears normal, and all the visible bones appear normal.

Our problem then is to try to find out the nature of this circular mass in the left chest posteriorly, which is in the approximate region of the apex of the lower lobe. Going back to the history we find a great many "red herrings" dragged across the trail. The history says that she had a negative x-ray ex-

amination two years before admission following exposure to a patient with tuberculosis. If that is reliable, it certainly would rule out both the congenital group of tumors and the benign tumors. If it was a tumor, it would have had to be malignant to reach this size in two years. Do we know where the x-ray examination was done?

DR JOSEPH HANELIN No. I am not familiar with the case.

DR SOSMAN It might make a difference if it were attached to the chest wall or free in the lung and moved up with cough or expiration. The one thing brought up more than anything else in the history is the story of tuberculosis. She is said to have had "a spot on the right lung" at the age of eighteen. There is no evidence of that at present. She had contact with a patient who was known to have tuberculosis, and this was the cause of her x-ray examination two years previously. Most important of all is the finding of acid-fast bacilli in smears taken from the left-lower-lobe bronchus. If that is reliable, which it certainly should be, we are forced to make a diagnosis of tuberculosis some-

ten hospital days the patient's course was not remarkable. She was afebrile. On the eleventh hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR MERRILL SOSMAN \*I think it is fair, inasmuch as the patient was admitted because of an x-ray finding from a chest clinic, to start with the films and then work back to the history, physical examination and laboratory findings.

We can see in this film that this is the chest of a young woman, "young" being comparative — any-

amination two years before admission following exposure to a patient with tuberculosis. If that is reliable, it certainly would rule out both the congenital group of tumors and the benign tumors. If it was a tumor, it would have had to be malignant to reach this size in two years. Do we know where the x-ray examination was done?

DR TRACY B. MALLORY It was done in one of the state sanatoriums.

DR SOSMAN Then it should be reliable. One other thing that we should note in evaluating the shadow is whether or not it was movable with the

FIGURE 1

one below one's own age is young and anyone above it is old. She has a single lesion in the left midchest, measuring 8 cm in diameter and not very sharply outlined. In the lateral view, lying well back posteriorly in the chest, the shadow is shaped a good deal like a gumdrop, the flat part being against the posterior chest wall and the anterior surface being sharply rounded or convex. The other findings in the chest appear perfectly normal. The heart is not displaced, the diaphragm is in normal position, the ribs are intact. The trachea appears normal, and all the visible bones appear normal.

Our problem then is to try to find out the nature of this circular mass in the left chest posteriorly, which is in the approximate region of the apex of the lower lobe. Going back to the history we find a great many "red herrings" dragged across the trail. The history says that she had a negative x-ray ex-

amination two years before admission following exposure to a patient with tuberculosis. If that is reliable, it certainly would rule out both the congenital group of tumors and the benign tumors. If it was a tumor, it would have had to be malignant to reach this size in two years. Do we know where the x-ray examination was done?

DR JOSEPH HANELIN No. I am not familiar with the case.

DR SOSMAN It might make a difference if it were attached to the chest wall or free in the lung and moved up with cough or expiration. The one thing brought up more than anything else in the history is the story of tuberculosis. She is said to have had "a spot on the right lung" at the age of eighteen. There is no evidence of that at present. She had contact with a patient who was known to have tuberculosis, and this was the cause of her x-ray examination two years previously. Most important of all is the finding of acid-fast bacilli in smears taken from the left-lower-lobe bronchus. If that is reliable, which it certainly should be, we are forced to make a diagnosis of tuberculosis some-

\*Radiologist, Peter Bent Brigham Hospital

where in the respiratory tract and presumably in the left lower lobe because that is where the smears were obtained. Were there any sputum examinations made? I did not notice anything about that in the report.

DR LAMAR SOUTTER The sputum was negative for acid-fast organisms.

DR SOSMAN So this is an isolated finding on bronchoscopic examination. We must make a diagnosis of pulmonary tuberculosis — postulating the ulcerating tracheobronchial type of tuberculosis — and then try to decide whether this shadow that we see can also be explained on the basis of pulmonary tuberculosis. It is a very rare type of shadow to be produced by tuberculosis in my experience. It is peripheral, which tuberculosis usually is, but it is round and smooth and homogeneous in density, and there is no evidence of cavity or any calcification in it. One of the most important things against it, I think, is the statement that she was afebrile. So we have to consider strongly the possibility that this was a separate lesion and not due to the presumed tuberculosis. Another suggestion in the history is the operation on the kidney some years before admission, and we have here a series of renal studies, both intravenous and retrograde pyelograms, all of which show a definite deformity of the right renal pelvis, which I think can readily be seen. It is quite possible, in fact quite probable, that this deformity is merely the result of previous operation and not of any intrinsic disease in the kidney at present. We notice that there is dilatation of the superior and inferior calyces, with a rather contracted central portion of the pelvis. The opposite renal pelvis on the left fills well except on one small film, where there is a suggestion of a negative shadow in the renal pelvis. It does not persist so I think we can disregard that.

The hysterectomy and salpingo-oophorectomy are readily explained by the tubal pregnancy and had nothing to do with the mass in the chest, particularly in this interval of time — three years.

Going back to the physical examination we note clubbing of the fingers. How can we tie that up with the mass that we find described in the history and at physical examination? Clubbing in my experience is most common in congenital heart disease. This patient had no murmurs or signs of heart disease. When patients have clubbing from heart disease they usually have murmurs, cyanosis and polycythemia due to the long-continued shunt of blood. The second most common cause of clubbing is primary tumor of the lung, which is nearly always malignant. I took care of a patient who had marked clubbing with a Pancoast type of tumor. Chronic infection of the lung is a third cause of clubbing of the fingers in my experience, and this, of course, can be a tuberculoma or a tuberculous area at the apex of the lower lobe. But, in my limited experi-

ence, clubbing in tuberculosis is usually found only in the far-advanced case with cavitation and secondary infection. I would expect it to be quite rare in a lesion of such short duration as this. A fourth cause of clubbing is polyposis of the intestine, which is very rare indeed. There is no gastrointestinal examination here so we cannot consider that.

That about covers my discussion except to say that I cannot explain the dyspnea, the rapid breathing, the choking spells and wheezing respirations noted earlier in the history. The hoarseness continued, and it is quite possible that it was due to tuberculosis of the larynx. This would tie up both things on one foundation. But I presume that the larynx was inspected at the time of bronchoscopy.

DR EDWARD B. BENEDICT That is right.

DR SOSMAN And nothing abnormal was seen.

DR BENEDICT The bronchoscopy was negative.

DR SOSMAN If there was enough tuberculosis to cause hoarseness, there should have been something visible on the vocal cords, either thickening or reddening.

So, to sum up this short and very easy case, I may say we are forced to make a diagnosis of pulmonary tuberculosis because of the positive sputum. I would like to tie up the chest lesion with tuberculosis also and call it tuberculoma. If so, one ought to see a large area of consolidation or perhaps atelectasis due to the tuberculosis of the ulcerating tracheobronchial type. But I suspect that there was a separate primary tumor of the lung in addition. Regarding the type of tumor, it is pure speculation in my experience to try to guess the kind of tumor a given patient has unless it has some of the characteristic findings, which this patient did not have. If we want to play poker, which I think is legal in this type of exercise, we may guess that it was nonmalignant because it was located opposite the seventh rib, and yet the ribs resected were the fifth and sixth, leaving the seventh rib intact, which puzzles me a little bit. If it were a malignant tumor invading the chest wall, I would assume that a good surgeon would excise the whole area including the seventh rib. Is that legal?

DR MALLORY It is done. Does anyone want to ask any questions?

DR SOSMAN I would gladly accept any suggestions or help.

DR BENEDICT I do not believe we know what Dr Sosman's diagnosis is. Is it a benign tumor of the lung?

DR SOSMAN No, I think the development of this tumor in two years is against a benign tumor of the lung. My diagnosis, which is based particularly on the acid-fast bacilli that were found, is pulmonary tuberculosis and probably a tuberculous lesion in the apex of the left lower lobe. I would put carcinoma second because of the rapid growth in two years.

## CLINICAL DIAGNOSIS

Carcinoma of lung (before acid-fast organisms were found)

## DR SOSMAN'S DIAGNOSIS

Pulmonary tuberculosis (from bronchoscopic washings)

Tuberculoma?

Carcinoma of lung, apex of left lower lobe?

## ANATOMICAL DIAGNOSIS

*Epidermoid carcinoma of lung, left lower lobe*

## PATHOLOGICAL DISCUSSION

DR SOUTTER I operated on this woman. We made a tentative preoperative diagnosis of bronchiogenic carcinoma. This was before the report of the bronchoscopic smears were received on the ward. The incision was made through the bed of the fifth rib to enable us to get above where the tumor was adherent to the chest wall. The tumor was adherent over the sixth rib. If one looks at the postoperative film, one sees the area of absent rib where the tumor was adherent. The appearance of the tumor suggested malignancy. It protruded from the lung tissue and seemed to invade the chest wall. We did a left lower lobectomy, going extrapleurally, and afterward resected that part of the chest wall to which the tumor had been adherent.

DR SOSMAN That is rather surprising because the sixth rib is at the upper edge of the shadow. The center of the tumor is opposite the seventh rib posteriorly.

DR SOUTTER The tumor was adherent to the chest wall at its apex and not at its center.

DR MALLORY The lobe that was resected showed a large spherical area of epidermoid carcinoma near the apex. We searched very carefully and were not able to find any trace of tuberculosis. I have no explanation for the acid-fast bacilli. I would hate to suggest the bronchoscope.

DR BENEDICT Of course it is possible there was tuberculosis in the other lobe that we knew nothing about. I was as surprised as anyone when tubercle bacilli were found. There must have been a mistake somewhere.

DR MALLORY We must remember that acid-fast bacilli do not always mean tuberculosis although in the sputum the chance of anything else is so slight that we feel safe in neglecting any other possibility. But we have no real knowledge that they were tubercle bacilli.

DR ALLEN G. BRAILEY Where did the tumor arise?

DR MALLORY From one of the secondary bronchi running to the apex of the lower lobe. It was completely occluded and surrounded by tumor, and the bronchus leading still higher up was com-

pressed by the mass. The regional lymph nodes were normal. Tumor cells were found in the parietal pleura after it was resected.

DR BENEDICT The bronchoscopy was negative as you know, but I would like to point out that in that area bronchoscopy probably would be negative for carcinoma. We would not be able to reach a tumor in the apex of the left lower lobe. In a series of 309 cases of proved carcinoma that were bronchoscoped by me in this hospital, there were positive biopsies in 61 per cent. Gibbon and his associates\* in Pennsylvania have had positive cytologic studies from bronchoscopic washings in 89 per cent of 105 cases studied. Our figures are not so good on bronchoscopic washings, nor have we done as many. I would say carcinoma was definitely not ruled out at this examination. We have had a few cases with both tuberculosis and carcinoma.

A PHYSICIAN Was a Papanicolaou stain done?

DR MALLORY Yes, and it was negative.

\*Gibbon J. H., Jr., Clerf L. H., Herbut P. A., and DeTurck J. J. Diagnosis and operability of bronchiogenic carcinoma. *J. Thoracic Surg.* 47:419-427, 1948.

## CASE 34482

## PRESENTATION OF CASE

A sixty-five-year-old woman was admitted to the hospital because of pain in the right side of the face and ptosis of the right eyelid.

About two years before entry the patient began to notice easy fatigability. Eight months before admission, during a routine checkup, she was found to be anemic. She was given liver injections over the following three months and felt improved. Six months before admission the third right upper molar became sensitive to heat, cold and pressure of mastication. A month later the patient began to have a watery discharge from the right nostril, always in the morning and not during the rest of the day. Three months before entry the nasal discharge, still limited to the right nostril, became bloody. The pain increased in severity and spread to the right temporal region. Except for some dried blood in the right nostril an ear, nose and throat specialist could not find any abnormality. Six weeks before admission roentgenograms of the sinuses were reported to be normal. The pain continued to increase, became almost constant and required codeine for relief. It was characterized by a dull, dead ache spreading up from the right maxilla to the temporal region, behind and into the eye, rarely crossing over a little to the left eye. Occasionally the ache was interrupted by shooting pains in the same regions. About ten days before entry the right upper eyelid began to droop. This was followed by diplopia and, three days later, by complete ptosis.

There had not been any weight loss, and appetite was good. There was no history of earache, dis-

charge from the ear, tinnitus, dizziness, nor of unsteadiness, awkwardness or weakness of the arms or legs. Five days before admission a spinal puncture showed an initial pressure equivalent to 65 mm of water, on jugular compression to 110 mm, and on final pressure to 60 mm, a total protein of 23 mg per 100 cc, a negative test for globulin, 1 neutrophil and chloride of 737 mg per 100 cc.

Physical examination showed complete ptosis of the right eyelid, lateral deviation of the eye and almost complete ophthalmoplegia. The right pupil was dilated and did not react to light or accommodation. Visual acuity, fields and fundi were normal. The left eye was not remarkable. There was no sensory impairment, deviation of the jaw, facial-nerve weakness or impairment of hearing. Speech, palate and tongue were normal. Neurologic examination was otherwise negative. An ear, nose and throat consultant found some bloody mucus on the posterior wall of the right nasopharynx.

The temperature, pulse and respirations were normal. The blood pressure was 120 systolic, 80 diastolic.

The hemoglobin was 13.6 gm, and the white-cell count 10,400, with 74 per cent neutrophils. The urine was negative for Bence-Jones protein. The nonprotein nitrogen was 28 mg, the total protein 6.36 gm, the albumin 4.38 gm, the globulin 1.98 gm, the phosphorus 4.1 mg, and the calcium 10.1 mg per 100 cc. The blood Hinton test was negative.

Roentgenograms of the skull and sinuses revealed a calvarium of normal contour but rather diffusely vascular. There was increased density in the region of the sphenoid sinuses on the right, and the outline of the floor of the sella turcica was not clearly seen. There appeared to be some calcification in one or both internal carotid arteries near the sella. The bone partitions of the ethmoid sinuses were somewhat hazy.

In the hospital the patient continued to complain of pain. There were no changes in her general or neurologic status. On the eighth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. DAVID G. COGAN: The combination of pain in the face and ptosis suggests rupture of an intracranial aneurysm, but there is no history of hemicranial headaches to go with this diagnosis, and the onset was apparently not sudden. The pain in the tooth may have been a local affair, but the fact that it was right-sided, as was the pain in the face, and chronologically related to the rest of the history, requires that we assume that it had some correlative significance, it may well have been a paresthesia from central involvement of the right fifth nerve. Similarly, the bleeding from the nose and serous discharge may have been a local affair, but the fact that it was unilateral and on the same side as the rest of the patient's symptoms requires

that we consider its most serious implication and assume it to have been an ulcerative process with rhinorrhea from a cerebrospinal fistula. I do not know why the discharge should have been most evident in the morning. The negative findings on physical examination of the nose and the negative x-ray findings do not rule out carcinoma of the nasopharynx. We have recently seen a patient with symptoms almost identical to those presented by this patient in whom carcinoma of the nasopharynx was ultimately found, but in the stage comparable to that of this patient no abnormality was found on examination of the nasopharynx or on x-ray examination.

The pain in this patient was more or less continuous and progressive. There was evidently preferential involvement of the second division of the trigeminal nerve. This, together with third-nerve paralysis, points to a lesion behind the superior orbital fissure and lateral to the sella turcica. Pain is not characteristic of benign lesions in this region and, therefore, suggests a malignant tumor extending from the nose into the subarachnoid space.

The spinal-fluid findings were noncontributory, the only thing of interest being the low cerebrospinal-fluid pressure. A reasonable explanation for this would be the cerebrospinal fistula, and it would be interesting to know whether prolonged jugular compression caused an increase in the rhinorrhea. The only noteworthy feature about the third-nerve paralysis is that the pupil was dilated. Lesions immediately behind the superior orbital fissure frequently do not cause enlarged pupils, presumably owing to coincident involvement of the sympathetic pathways. The lesion in this case might be thought, therefore, to have been nearer the cavernous sinus than the superior orbital fissure. It is also noteworthy that the optic nerve was not involved as so frequently happens with the tumors extending from the sphenoidal region. The x-ray films taken after admission showed an increased density in the sphenoid sinuses on the right with obscuration of the floor of the sella turcica. Dr. MacMillan, radiologist at the Massachusetts Eye and Ear Infirmary, tells me that this is compatible with a tumor extending from the sphenoidal region up through the sella turcica. The x-ray finding of calcification in the carotid arteries is not infrequent in people of this age group.

In summary, the patient was a sixty-five-year-old woman whose outstanding symptoms were severe pain in the right trigeminal region and paralysis of the right third nerve. This suggests a lesion lateral to the sella turcica on the right side. The rhinorrhea and x-ray findings are compatible with a tumor connecting the nasopharynx and cranial cavity. It seems to me that the only reasonable diagnosis is an erosive tumor extending either from the nasopharynx or primarily from the sphenoid sinus up into the cranial cavity. The presence of pain and erosiveness points to malignant tumor.

The two predominant types of cancer found in this region are lymphosarcoma and carcinoma. The lymphosarcomas are less apt to cause pain but are more apt to be diffuse, less circumscribed and less erosive. Also, they are frequently characterized by auditory symptoms unlike those produced by carcinoma. This patient therefore appears to have had a carcinoma. On the basis of frequency, I would suggest a diagnosis of transitional-cell carcinoma of the sphenoid, with fistula connecting the cranial cavity and nasopharynx.

DR TRACY B. MALLORY: Are there any questions that you would like to ask Dr. Cogan, or any other suggestions? Perhaps we should see the x-ray films.

DR JAMES J. McCORT: The soft-tissue mass overlying the sphenoid sinus can be seen in this region, causing some density of the sphenoid sinus. The posterior wall of the sphenoid sinus appears to be missing. It is probably eroded. On this film the floor of the sella turcica is eroded, with no local identification. There are a few flecks of calcification lying apparently over the sella turcica, which as the protocol says may be in the carotid arteries. There is no curved linear distribution of the calcification, which might indicate aneurysm.

DR COGAN: Are you able to differentiate a metastatic and a primary lesion?

DR McCORT: Not here, since we do not have a complete skull series.

DR CHARLES I. JOHNSON: I would like to take issue with Dr. Cogan on the fact that the nose and throat specialist was not able to find a carcinoma in the nasopharynx. This was not a nasopharyngeal tumor, it was a sphenoid tumor. With the aid of a nasopharyngoscope a streak of bloody mucus could be seen coming from the ostium of the sphenoid and joining the posterior ethmoid region. There are four ways of examining the nasopharynx by roentgenograph, mirror, finger and nasopharyngoscope. None of these ways, except x-ray examination and nasopharyngoscope, would have helped in this case. If blood had not been coming out at that instant, the nasopharyngoscope would not have helped. All one would have is the x-ray film. In the presence of suggestive x-ray findings, exploration should be done.

DR COGAN: The reason I was discounting the negative x-ray examination is that the other patient to whom I referred as having identical symptoms, and who was subsequently found to have a transitional carcinoma of the nasopharynx, also had negative findings in the nose and a negative x-ray examination.

DR JOHNSON: How long before the tumor was found was the examination done?

DR COGAN: He was seen by a nose and throat specialist, not by Dr. Johnson, because of recurrent nosebleeds and septal deviation. He had a high blood pressure. Examination of the nasopharynx was negative. He came into the Emergency Ward

two months later with a severe epistaxis and was again examined by a nose and throat specialist and the nasopharyngeal tumor was found.

DR JOHNSON: It means that the patient probably did not have a really good examination the first time.

DR COGAN: I assumed that the tumor could not be found.

## CLINICAL DIAGNOSIS

Transitional cell carcinoma

## DR COGAN'S DIAGNOSIS

Transitional cell carcinoma of sphenoid sinus

## ANATOMICAL DIAGNOSIS

*Transitional cell carcinoma of sphenoid sinus*

## PATHOLOGICAL DISCUSSION

DR JOHNSON: We explored the sphenoid sinus under local anesthesia and took off a good deal of the posterior part of the middle turbinate and removed the anterior face of the sphenoid sinus—removing a mucocele—and then found a large piece of tumor tissue. The superior wall of the sphenoid was gone, according to instrumentation—that is, according to the sensation one gets from instrumentation. We had to be a little careful because we thought there had been a cerebrospinal leak previously. I do not call this a nasopharyngeal tumor, it was a sphenoid tumor, and I do not see how one can possibly miss a nasopharyngeal carcinoma if all four methods of examination are resorted to.

DR CHARLES S. KUBIK: I have nothing to add to what is in the record. The ocular palsies localize the lesion with great precision, as Dr. Cogan has indicated. In this case it is interesting that although there had been a good deal of pain, there apparently was not enough involvement of the fifth nerve to cause sensory impairment.

DR MALLORY: The biopsy, as Dr. Johnson said, showed transitional-cell carcinoma, undoubtedly primary in the sphenoid. I believe you saw the patient in reference to treatment, Dr. Taylor.

DR GRANTLEY W. TAYLOR: My participation in this case was insignificant. The question arose whether or not we could relieve the symptoms. We have had a moderate amount of experience with these tumors. Some are responsive to irradiation—so much so that all symptoms are relieved to a considerable degree. Therefore, we started x-ray therapy, and the results were fairly good. The patient began to get significant relief from symptoms as soon as the treatment was started while she was in the hospital. She had less pain and had some comfort.

DR JOHNSON: I saw her yesterday. She is more comfortable. The ptosis is complete. Everything else is as it was except that she is more comfortable.

## VOX POPULI

THE shouting and the tumult have died away, many of the captains and not a few others have departed. If enough hearts are still humble America has weathered another of her periodic domestic crises, established by her inviolate constitution, and has again emerged as the most democratic nation of any consequence in the world.

This same world of mankind nearly half a century ago entered one of its great revolutionary cycles. Two world wars have been incidents in that cycle and persons of prominence, however important they may have seemed as good or evil influences, have been in many ways little more than symbols of the times in which they have lived. The significant forces have been not emperors or presi-

dents or politicians, not dictators or the champions of democracies, but dissatisfaction with their lot in life, and a great desire to change it, of vast segments of the population. Leaders are but levers that help to put the mass in motion and sometimes try to stop it. Once the reaction has started it usually goes on until its temporary destiny is fulfilled.

America's recent pilgrimage to the polls has shown that in the present instance the voice of the people is not that of the turtle. Patience with slow reforms and half measures is gone. All the countries of the world have turned more or less sharply to the left, and it is inevitable that America should also at least incline in that direction. And where else has government of the people, for the people and by the people a better chance of succeeding?

New experiences will come to this country within the next few years. Labor will have a larger share in government than ever before. Medicine will have to find improved methods of bringing its benefits to all the people if it is still to control its own destiny and escape the sloughs of despond into which it has fallen elsewhere.

The duty of every citizen now is to make a temperate democracy the most successful and the most desirable form of government on earth.

## THE MONTH BEFORE CHRISTMAS

THE Christmas Seal Campaign annually calls attention to a widely prevalent disease that, in spite of notable progress in control, accounts for a disheartening number of deaths, many of them avoidable. This year, from November 22 to Christmas Day, the National Tuberculosis Association again conducts its appeal for contributions to a program designed to prevent and control—and eventually to eradicate—tuberculosis. Throughout the land men and women are asked to give what may be regarded as a Christmas present to humanity: the money that provides the sole financial support of the national, state and local associations in their year-round work of control through education, case finding, rehabilitation and medical research.

There is some ground for comfort (but none for complacency) in the fact that since 1904, when the first nationwide, organized campaign against the disease was inaugurated, tuberculosis has declined from first to seventh place among the leading causes of death in the United States. This disease, whose cause is known and for which methods of control and cure are available still accounts for more deaths than any other disease among people from fifteen to forty-four years of age and still kills 50 000 Americans, including more than 1500 children, each year. A recent increase in the number of new cases in New York City and elsewhere\* re-emphasizes the need for constant alertness to the threat of more widespread infection. Careful estimates of 500,000 active cases in the United States are attended by the warning that only half of them are known to health authorities, the remainder of the patients presumably unaware of their infection and receiving no treatment, provide a reservoir from which the disease is easily spread. Education is thus of primary importance, for if people are made conscious of tuberculosis and its cause and means of prevention, they will more readily take action to protect themselves and their neighbors. The National Tuberculosis Association and more than three thousand affiliated organizations, in co-operation with the United States Public Health Service state and local health departments, physicians and nurses, work ceaselessly to persuade every person fifteen years of age and over to have regular x-ray examinations of the chest. In thousands of communities the tuberculosis associations and the local health authorities provide mass x-ray services large groups are examined quickly and at low cost, and in many sections the service is free. This program is based on a sound principle of preventive medicine: no complete control is possible until the unknown cases, which provide the source of infection, are recognized and the patients treated.

No endeavor to alleviate suffering remains unsupported by Americans. Each year, on the eve of the season of rejoicing and good will among men, their generous response to this appeal represents the conviction that man, in many ways, is his

brother's keeper. As a symbol of a united effort of relief and protection for the unfortunate, the Christmas Seal has fulfilled its office justifying the sentiment expressed in the lofty phrases of a great poet and divine of the sixteenth and seventeenth centuries: "Any man's death diminishes me because I am involved in Mankind."

## PENICILLIN FOR PROPHYLAXIS

THE prophylactic use of penicillin is receiving an increasing degree of attention. The drug is almost universally employed before and after tooth extractions or other dental manipulations particularly in patients who are considered to be susceptible to bacterial endocarditis.<sup>1</sup> By the same token, penicillin is given liberally in the treatment or prevention of mild respiratory infections in patients who have had rheumatic fever<sup>2</sup> or in whom subacute bacterial endocarditis has been arrested or cured by penicillin therapy.<sup>3</sup> The administration of penicillin during severe influenza-virus infections or in certain cases of extensive viral pneumonia may also prove useful in preventing the occurrence or spread of bacterial complications. Penicillin has also been used both with and without influenza-virus vaccine in the prophylaxis of upper respiratory infections.<sup>4, 5</sup>

The use of penicillin in the prophylaxis of venereal infections is an obvious corollary to its use in the treatment of these diseases. It is well to bear in mind that although relatively small doses of penicillin are adequate in the prevention of syphilitic infection in the rabbit,<sup>6-8</sup> the use of penicillin in the small doses that are effective in the treatment of simple gonococcal urethritis has been followed, in a number of reported cases, by the development of syphilis from what probably was the same exposure.<sup>9</sup>

A preliminary trial of the use of penicillin tablets for the prevention of gonorrhea<sup>10</sup> has nevertheless yielded encouraging results from the point of view of reducing the incidence of this infection. In the controlled but brief study thus far recorded there has been no evidence of sensitization to penicillin, no apparent development of penicillin-fast strains of gonococci and no recognized instance of suppressed syphilitic infection. Further reports of

\*Editorial: Increase in tuberculosis. *New Eng. J. Med.* 239:796, 1948.

this and other studies will, of course, be awaited with interest

Some observations have already been made also on the administration of oral penicillin instead of sulfonamides for the prevention of recurrences in cases of rheumatic fever<sup>2, 11</sup> It is too soon to evaluate the results in these cases The potential complications of the widespread use of penicillin and particularly the potentialities of producing and disseminating resistant strains by continuous prophylaxis with this antibiotic are as yet unknown The report<sup>11</sup> of the discovery of highly resistant strains of streptococci in children after they had received penicillin prophylactically by mouth for some time is rather disturbing The data in this regard, however, are inadequate for proper evaluation and require confirmation, particularly in view of the fact that these resistant strains have subsequently been eliminated from the same patients by the use of larger oral doses of penicillin and also because the development of resistant strains of hemolytic streptococci has not yet been encountered during treatment of active infections by any other observers

#### ROSTER OF PHYSICIANS

ACCORDING to the Bureau of Medical Economic Research of the American Medical Association, there were approximately 199,755 living physicians in the United States on June 1, 1948 The Bureau for over a year has been developing a punch-card system of tabulating physicians, and hopes to have the roster completed early in 1949

The most populous state so far as physicians is

concerned is New York, with 30,970 Nevada, with 198 has the fewest Massachusetts stands sixth in line with 9102, of whom approximately two thirds are fellows of the Massachusetts Medical Society

The 3000 who are not fellow members should be our grave concern Those who are eligible for fellowship should be urged to apply Those who are not now eligible but are capable of becoming so should be encouraged to improve their standing in the profession and should be given all possible assistance in making the effort

Fourth-year students in approved medical schools are reminded of the *Journal's* prize essay competition on preventive medicine

For further information see *The New England Journal of Medicine*, September 30, 1948, p 525, or write to the editor

#### MASSACHUSETTS MEDICAL SOCIETY

##### DEATHS

BARNES — Henry Barnes, M.D., of New Bedford, died on May 29 He was in his seventy-first year

Dr Barnes received his degree from Columbia University College of Physicians and Surgeons in 1903 He was chief of staff at Acushnet Hospital and a fellow of the American Medical Association

GLASSMAN — Nathan B. Glassman, M.D., of Boston, died on June 8 He was in his fifty-ninth year

Dr Glassman received his degree from College of Physicians and Surgeons, Boston, in 1916 He was a fellow of the American Medical Association

His widow, a son and a daughter survive

MAILEY — H. Douglas Mailey, M.D., formerly of Andover, died on October 14 He was in his thirty-fourth year

Dr Mailey received his degree from Boston University School of Medicine in 1942 He was formerly radiologist at the Lahey Clinic

His widow, a son, a daughter, his father and two sisters survive

#### MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

##### PREMARITAL AND PRENATAL BLOOD TESTS

Hospital administrators and laboratory directors are informed that it has been brought to the attention of the Department that laboratories not approved for performing premarital and prenatal blood tests have been accepting specimens from physicians to be examined for this purpose They are requested to call to the attention of laboratory personnel that this practice is contrary to law If a laboratory does not appear among those in the following list, physicians should be told that all specimens should go to a laboratory that has approval for doing these tests

LOCATION	LABORATORY
Boston	Boston Dispensary Boston Health Department Commonwealth Clinical Laboratory Learr Laboratory Massachusetts General Hospital Massachusetts Memorial Hospitals (Genitoinfectious Disease Clinic) State Wassermann Laboratory
Brockton	Brockton Health Department
Brookline	Sias Laboratory (Brooks Hospital)
Clinton	Clinton Hospital
Fall River	Union Hospital
Fitchburg	Burbank Hospital
Great Barrington	Fairview Hospital
Holvoke	Holvoke Hospital Providence Hospital
Lowell	Lowell General Hospital
Montague City	Farren Memorial Hospital
New Bedford	Clinical Laboratory St. Luke's Hospital
Newton	Newton-Wellesley Hospital
North Adams	North Adams Hospital
Pittsfield	St. Luke's Hospital House of Mercy Hospital
Salem	Salem Hospital
Springfield	Mercy Hospital
Tewksbury	State Infirmary and Hospital
Westfield	Noble Hospital
Worcester	St. Vincent Hospital Worcester City Hospital Worcester Health Department

Attention is called to the fact that laboratories that have approval for doing rapid blood Hinton tests for transfusions only are not recognized as qualified to perform premarital and prenatal blood tests.

If a laboratory wishes to be added to the attached list, it should seek approval of the Department for a diagnostic serologic test for syphilis.

#### CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The December schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Haverhill	December 1	William T. Green
Lowell	December 3	Albert H. Brewster
Salem	December 6	Paul W. Hugenberger
Brockton	December 9	George W. Van Gorder
Greenfield	December 13	Charles L. Sturdevant
Gardner	December 14	Carter R. Rowe
Pittsfield	December 15	Frank A. Slowick
Worcester	December 17	John W. O'Meara
Springfield	December 21	Garry de N. Hough, Jr.
Hyannis	December 23	Paul L. Norton
Fall River	December 27	David S. Grice

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

#### MISCELLANY

##### MASSACHUSETTS DEPARTMENT OF EDUCATION, DIVISION OF VOCATIONAL REHABILITATION

Handicapped persons can be helped by the Division of Vocational Rehabilitation, Massachusetts Department of Education, 200 Newbury Street, Boston. The aim of this division is to improve 'the physical, mental, social, vocational and economic usefulness' of all handicapped persons who are over sixteen years of age and who have a mental or physical disability that is a substantial employment handicap. This division may furnish to eligible clients counseling, guidance training in occupations, refresher training and placement.

The medical or surgical treatment for physical or mental handicaps that are static and may be removed or appreciably alleviated within a reasonable period may be purchased by this division. These services are available to those in economic need and are paid on a fee-for-service basis to physicians, surgeons, psychiatrists and other medical agencies of the patient's choice.

For example, through this division crippled persons may be furnished appliances or taught sedentary trades or both. Cardiac patients may learn lighter trades. Newly ruptured persons may have surgical care. Amputees may be provided with artificial limbs.

It is hoped that the recent increase in the all-inclusive per-diem allowance by this division to hospitals servicing its clients will increase the number of co-operating hospitals, making the services more readily available. The all-inclusive per-diem allowance has been increased to \$10 as of October 1, 1948, in hospitals whose per-diem costs per patient are \$10 or over.

The division will be pleased to furnish further information to patients, physicians, hospitals or other agencies concerning this program of vocational rehabilitation and physical restoration.

#### CORRESPONDENCE

##### DEPRIVATION OF LICENSES

*To the Editor:* At the meeting of the Board of Registration in Medicine held October 21, it was voted to suspend for six months the registration of Dr. Glenn F. Muntz, 30 Huntington Avenue, Boston, and to revoke the registration of Dr. R. Reyes Garcia, 1562 Main Street, Springfield.

GEORGE L. SCHATZ, M.D. *Secretary*  
Board of Registration in Medicine

State House  
Boston

#### BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*History of the Medical Society of the County of Westchester, 1797-1947. A compilation from the available minutes of the Society and various contemporary sources during the years for which the minutes were lost.* 12°, cloth, 193 pp. New York: Medical Society of the County of Westchester, 1947. \$2.50.

This history of a county medical society of New York has been compiled by the current historian, Dr. Laurence D. Redway, from the available minutes of the Society and contemporary sources. The Society was founded in 1797 and has had a continuous existence until the present time. The text is concluded with two short historical sketches of the Department of Public Welfare of the County, and of the Westchester Nursing Association. The book is privately printed. The lack of an index detracts from its reference value.

*The Care and Management of Laboratory Animals Handbook of the Universities Federation for Animal Welfare With an appendix on statistical analysis* By Aastair N Woden, M A (Cantab), B Sc (Lond), M R C V S, A R I C, Milford Professor and director of research in animal health, University College of Wales, Aberystwyth With a foreword by Professor T Dalling, M A, M R C V S, F R S E, director, Veterinary Laboratory, Ministry of Agriculture and Fisheries, Welbridge, Surrey 8<sup>o</sup>, cloth, 376 pp, with 70 illustrations—Baltimore Williams and Wilkins Company, 1947 \$8 50

This handbook, the composite work of a number of experts in animal husbandry, has been produced under the sponsorship of the Universities Federation for Animal Welfare, London The first three chapters deal with law and practice and the laboratory rights of the animal, the animal laboratory, its construction and maintenance, and the pests of the animal house and their control The following chapters are devoted to the care and handling of animals used in laboratory work and their diseases Separate chapters are given to 19 different small animals, birds, amphibia and fresh-water fish An appendix comprises a technical conspectus of the elements of statistical analysis A selected list of references is appended to each chapter Indexes of subjects and authors are appended to the text The volume is well published in every way This exceptional handbook has long been needed and is an essential reference work It should be in all libraries, general and medical, and in all laboratories where animals are kept for research, control and production purposes Likewise, it should prove valuable to all persons handling small animals

*Manual for Laboratory Work in Mammalian Physiology* By Fred E D'Amour and Frank R Blood 8<sup>o</sup>, paper 162 pp, with 207 illustrations Chicago University of Chicago Press, 1948 \$2 75

This manual is based on a group of fifty experiments in which the rat is used exclusively It is hoped that the use of this convenient animal will greatly simplify the problem of laboratory animal supply The materials and equipment and procedure for each experiment are simply described and illustrated The use of anesthesia in the experiments is stressed The binding is the ring-type The text is well printed The manual should prove valuable to students in physiology

*Neuroanatomy* By Fred A Mettler, A M, M D, Ph D, associate professor of anatomy, College of Physicians and Surgeons, Columbia University Second edition 4<sup>o</sup>, cloth, 536 pp, with 357 illustrations, including 33 in color St Louis The C V Mosby Company, 1948 \$10 00

This second edition of a standard textbook has been revised considerably, and material on the blood supply and venous drainage of the various portions of the neuraxis has been added The volume is well published in every way and is an essential book for all medical libraries and for neurologists and neurosurgeons

## NOTICES

### ANNOUNCEMENTS

Dr William L Davis announces the opening of his office for the general practice of medicine at 262 Beacon Street, Boston

Dr Elliot L Sagall announces the removal of his office for the practice of internal medicine to 371 Commonwealth Avenue, Boston

### MOUNT AUBURN HOSPITAL TUMOR CLINIC

A tumor clinic has been established at Mount Auburn Hospital, 330 Mt Auburn Street, Cambridge The clinics are held on Fridays at 1 30 p m in the Out-Patient Department

The services of the clinic are available to private patients on a consultative basis Patients are seen by appointment only An abstract of the referring physician's findings should accompany the patient

At the clinic an examination will be made calling in the necessary consultants in various specialties After examination a group opinion will be given

A letter stating the results of the examination and the opinion will be sent to the physician The patient will be directed to return to him

The fee for this examination and opinion will be \$10 00

If special examinations, biopsy, laboratory, x-ray, endoscopy and so forth are thought necessary, the referring physician will be notified

Appointments can be made by telephone (TRowbridge 6-5680, Extension 219)

### MASSACHUSETTS GENERAL HOSPITAL RESEARCH COUNCIL

A meeting of the Massachusetts General Hospital Research Council will be held in the Bigelow Amphitheater on Wednesday, December 1, at 4 30 p m

#### PROGRAM

The Effects of Experimental Potassium Deficiency, Lutt I Gardner, Charles D Cook, Helen Berman, Elsie A MacLachlan and Nathan B Talbot (twenty minutes)

Recent Developments in the Study of the Metabolic Functions of the B Vitamins Nathan O Kaplan (twenty minutes)

### NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, December 2, at 7 15 p m, in the classroom of the Nurses' Residence Dr Harold H Rosenfield will discuss the subject "Some Abnormalities of the Third Stage of Labor Presentation of cases" Dr Mabelle C Hiscock will be chairman

### NEW ENGLAND HEART ASSOCIATION

A meeting of the New England Heart Association will be held at the Massachusetts General Hospital on Monday, December 6, at 8 15 p m, Dr Paul D White presiding

#### PROGRAM

Syphilitic Aortic Regurgitation A follow-up study of 100 cases Drs James H Currens and William R Hill

A Venous Shunt for Marked Mitral Stenosis Drs Edward F Bland and Richard H Sweet

Prognosis in Essential Hypertension Eight-year follow-up of 430 cases Drs Robert S Palmer, Dorothea Loeb-bourrow and Carl Doring

Effect of Skin Resistance in Relation to the Newer Electrocardiographic Leads Dr Hsueh-hwa Wang, Mr Maurice Rappaport and Dr Conger Williams

Physique in the Young Coronary Patient Drs Stanley Garn and Menard M Gertler

The National Heart Institute Dr Paul D White

Interested physicians and medical students are cordially invited to attend

### NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

A meeting of The New England Society of Anesthesiologists will be held in the auditorium of Building A, Boston University School of Medicine, 80 East Concord Street, Boston, on Tuesday, December 14, at 8 00 p m The program will include the following reports on medical missions to Europe

Mission to Germany Dr Henry K Beecher

Mission to Poland Dr Meyer Saklad

Physicians and medical students are invited to all meetings

(Notices concluded on page xv)

## NONTUBERCULOUS SPINAL EPIDURAL INFECTIONS\*

A PRICE HEUSNER, M.D.†

BOSTON

**N**ONTUBERCULOUS spinal epidural infections are infrequent disorders that merit periodic reconsideration by the profession at large because of the heavy responsibility accruing to the practitioner who first visits a patient thus afflicted. Final diagnosis and definitive treatment of these infections are now regarded as functions of specialists, but the decisive factor in the outcome of most cases is the celerity with which the first attending physician suspects the probable nature of the ailment and summons expert aid. Thus early diagnosis leading to prompt surgical intervention is regularly rewarded by total recovery. On the other hand, even brief delay of operation can vitiate all subsequent efforts to avert permanent paraplegia or quadriplegia with an attending loss of control over bladder and bowel, an insensible skin predisposed to bedsores and a host of secondary complications inherent in this type of disability. Such crippling effects are traceable to the fact that undrained spinal epidural sepsis can produce irreversible neurologic damage with tragic suddenness, and numerous attempts<sup>1-4</sup> have been made to ensure universal recognition of this dreadful potentiality. Nevertheless, enduring paralyses continue to follow in the wake of these lesions with unnecessary frequency.

It is clearly a matter of general interest to inquire into the factors that seemingly perpetuate these costly delays. Such is the main purpose of this paper, and its conclusions may be anticipated to the extent of declaring that the situation will be rectified only when the entire medical profession becomes sufficiently familiar with the clinical aspects of epidural inflammation to suspect its presence at a preparalytic phase of the disorder. During this remediable stage, the illness is almost routinely mistaken for some more everyday ailment, and in far too many cases the patient reaches the surgeon only after paralysis is complete and all hope for restoration of function has vanished.

The present study will also be of interest to specialists in the field. The literature contains reports on more than 200 cases of spinal epidural sepsis and several excellent review articles,<sup>2-5</sup> but clinical papers have with few exceptions<sup>2,3,6</sup> dealt with one or at most a few cases. No analysis of the clinical features of a relatively large group of cases treated in one clinic is available. Nor has any article attempted either to describe the role or to estimate the value of modern antibacterial agents in a large series of such cases. Information on these matters together with a note on the mechanism of the paralyses is here presented.

### MATERIAL AND CLASSIFICATION

The present report is based upon an analysis of the 20 consecutive cases of nontuberculous spinal epidural infection receiving definitive treatment in this clinic since its organization in 1930.†

It is customary to divide the lesions under consideration into acute spinal epidural abscesses, including metastatic and osteomyelitic, and chronic spinal epidural granulomas. More elaborate nomenclatures have been proposed<sup>5</sup> wherein etiologic pathologic, anatomic and temporal designations are compounded into long, hyphenated names that are both more descriptive and of more prognostic import than those of the above classification. Unfortunately, these are too cumbersome for ordinary usage. The present material is therefore presented under a modification of the customary classification: acute spinal epidural infections, including metastatic and osteomyelitic, and chronic spinal epidural infections, including metastatic and osteomyelitic.

As the names suggest the first variety runs a rapid clinical course while the second develops insidiously. It is important to retain this distinction in clinical tempo if only to stress that surgical urgency increases *pari passu* with the rate of clinical

†During this eighteen year period paraplegic patients with burned-out epidural sepsis have come to this clinic for rehabilitation, but their definitive treatment had been carried out elsewhere and they are not included in this study. Also omitted from consideration here are patients who suffered from tuberculous, syphilitic and coccal epidural infections and a few cases of spinal epidural sepsis all concurrently treated.

†Instructor in neurology, Harvard Medical School; associate surgeon for neurosurgery, Boston City Hospital.

evolution. If this concept is borne in mind, cases unfolding at a subacute rate will automatically be deemed urgent, and a third major category may thus be safely avoided. As is shown below, prognostic implications probably justify the continued

does not enable one regularly to predict whether abscess or granuloma will be found.

#### ETIOLOGY

It is generally agreed that a spinal epidural infection is traceable to a primary focus of inflam-

recognition of metastatic and osteomyelitic subdivisions within each major category. In the former group, no vertebral osteomyelitis is demonstrable, whereas in the latter, a spinal caries appears to be the reservoir of sepsis from which the

mation located elsewhere in the body either near to or remote from the epidural compartment. In the former case, invasion of this space is thought to occur either by *direct extension* from such a focus as a pre-existing vertebral (or costal) osteomyelitis,

epidural lesion arises. It is preferable, however, to speak simply of acute and chronic "infections" rather than to imply a fixed correlation between the age of a lesion and its gross pathological appearance. This is because the chronicity of an infection

or by *lymphatic spread* from a paraspinal lesion such as a retropharyngeal abscess or a mediastinal infection. In osteomyelitic cases, the caries, in its turn, may sometimes be traced to a remote reservoir of sepsis such as a chronic acne. In cases in which

a distant focus is the direct source of the epidural lesion, bacteria are believed to reach the normal epidural fat (a *locus minoris resistentiae*) by *hematogenous metastasis* from a furuncle, cellulitis, pyleitis or the like. *Direct inoculation* of the epidural tissues as a result of faulty asepsis during the performance of spinal puncture, or by penetrating wounds of the spine, is said to be another mechanism capable of exciting epidural suppuration but no example has been encountered in this clinic.

It must be admitted that in a few of the presumed metastatic cases, exhaustive searches fail

the appraisal of any puzzling spinal ache or paretic ailment.

Table 1 summarizes the etiologic data on the present material.

The bacteriologic uniformity of these cases is striking. *Staphylococcus aureus* was recovered in pure culture from the epidural space of every patient except 1 (Case 20) in whom no cultures were made. It is generally agreed that this is the most frequent offending organism, but it is also reported<sup>2, 3, 5</sup> that the pneumococcus, streptococcus, *Bacillus pyocyaneus* (*Pseudomonas aeruginosa*), ty-

to uncover primary foci, and, as might be expected, no remote focus can be found for the vertebral caries in a high percentage of the osteomyelitic cases. Some authors<sup>6</sup> hold that all cases are but complications of a vertebral osteomyelitis that frequently escapes detection only because the search for it is seldom diligent. Others<sup>7</sup> dissent from this contention, and while there is more to be said on this score, I pause over it here merely to emphasize that antecedent infections outside the epidural compartment are of such frequent occurrence (75 per cent of cases in this series) as to be worthy of detailed inquiry in

phoid bacillus and other bacteria are occasionally found. (This discussion does not concern the frequent epidural extensions from tuberculous caries or those sometimes arising from actinomycotic and echinococcal disease.)

Table 1 shows that among the 18 acute cases, antecedent infections outside the epidural space were discovered in 14 (78 per cent). These foci were skin lesions in 7 (39 per cent), vertebral osteomyelitis in 6 (33 per cent) and pyleitis in 1 (6 per cent). The role of cutaneous infections is really greater than the 39 per cent indicates because

lesions of this type were the remote sources for the spinal caries in 2 of the acute osteomyelitic cases (Cases 15 and 18), thus raising the over-all incidence to 50 per cent among acute cases

Among skin infections, acne and furuncles were most frequent. They appeared to be the primary foci for 3 of the acute metastatic (Cases 1, 3 and 10), and the remote focus for the spinal caries in 1 of the acute osteomyelitic cases (Case 15). Of the former group, the most recent pustules had appeared healed for several days prior to the onset of the spinal disease, and blood cultures were sterile in the 2 cases in which they were obtained. In the latter case, however, the acne was active, and *Staph aureus* was recovered from the blood stream as well as from the epidural space.

Infected operative sites, cutaneous in 3 cases and deep in 1, appeared to be the primary foci for 2 acute metastatic lesions and the distant foci for the spinal caries in 2 acute osteomyelitic cases. The 3 cellulitides involved an amputated toe (Case 18), a suprapubic cystotomy wound (Case 2) and a virtually healed empyema sinus (Case 6), the deep operative sepsis was proved by autopsy to be in an apparently healed nephrectomy bed (Case 14). In all these patients the foci were active at the onset of spinal symptoms, and blood cultures were positive for the *Staph aureus* in the only 2 cases (Cases 14 and 18) in which such studies were made.

The remaining cutaneous foci, an infected corn (Case 5) and a traumatic cellulitis of the forearm (Case 11), were found to antecede acute metastatic lesions. Both were suppurating at the onset of the spinal symptoms, and blood culture, omitted in Case 5, yielded the *Staph aureus* in Case 11.

In 1 acute metastatic case (Case 9), a pyelitis was demonstrated by pyelography. *Staph aureus* was found in the urine, the blood stream and the epidural space.

Of the chronic lesions, that in Case 20 was osteomyelitic but without discernible remote focus from which the caries might have arisen. In this case, neither blood nor wound cultures were obtained. The other chronic lesion (Case 19) was without spinal caries or detectable distant focus. The blood culture was sterile on the fifty-fifth day of the illness but might have been otherwise during a bout of "grippe" that antedated spinal symptoms by several days.

Among the 6 acute osteomyelitic cases there were 3 (Cases 13, 16 and 17) in which no remote foci for the caries were found. In none of these was a bacteremia demonstrated after the onset of neurologic symptoms, nor did trauma appear in the histories.

In 4 of 12 acute metastatic cases no primary foci could be discovered, but 3 patients (Cases 4, 7 and 8) had suffered recent, though mild, closed spinal injuries (Table 1) — of the entire series of 20 patients, only 1 other (Case 11) gave a history of trauma.

Blood cultures, made in 3 of these cases, yielded *Staph aureus* only in Case 4.

Sex appeared to play no role in susceptibility to these lesions. On the other hand, a difference of age incidence between the metastatic and the osteomyelitic categories is readily apparent. The average ages at onset were 29.6 and 50.6 years respectively. This difference is more arresting if it is noted that among the 7 osteomyelitic cases, no patient was younger than 36 years, whereas among the 13 metastatic cases there were 7 patients in the teens and 2 in the twenties. Any significance attaching to this difference is not clearly evident, but, taken in conjunction with pathologic, clinical and prognostic dissimilarities yet to be considered, it influences me to retain the distinction between metastatic and osteomyelitic syndromes.

It must be emphasized that the foregoing list does not exhaust the causative possibilities. Indeed, cumulative experience<sup>2-6, 8</sup> indicates that almost any reservoir of sepsis caused by almost any pyogenic organism can occasion the development of an epidural lesion either directly by a hematogenous implant or sequentially by extension from an intermediately excited vertebral caries.

#### PATHOLOGY

Once established in the epidural space, infection spreads axially along the surface of the dural tube. Pus and granulomatous tissue in differing proportions usually accumulate in greatest amounts over the dorsum of this tube and exhibit little tendency to encircle it, although in osteomyelitic cases they occupy one or the other lateral epidural gutter at their site of origin from the bony lesion. Rarely, a lesion of bony origin is confined to the ventral compartment of the spinal canal. It is not entirely clear why the products of inflammation are thus deployed, but two discernible factors may be partially explanatory: the dorsal region is the normal disposition of the epidural fat, which, like adipose tissue elsewhere, offers little resistance to infection, and the ventral surface of the dural tube is moderately adherent to the underlying spinal ligaments, thereby affording a mechanical deterrent to the spread of infection that does not obtain dorsally where the dura lies free from the vertebral arches.

Among the acute cases, the epidural portion of the lesion was always predominantly granulomatous tissue. Usually, the red, friable tissue contained several tiny locules of pus that varied in amount from a mere droplet to 1, or at most, 2 cc. In 1 case (Case 6), however, no macroscopic pus was present, this lesion was thus a true "granuloma."

In 1 of the 2 chronic cases (Case 20), the lesion was a ventrally placed granuloma atop a cervical caries. In the other, a metastatic case (Case 19), the lesion consisted of two contiguous cocoons of granulomatous tissue, each containing about 5 cc of pus. The walls of these cocoons were friable.

and not fibrous, but this lesion was more nearly an "abscess" than that of any other case in the entire series

Table 1 shows the axial extent of all lesions as determined by operative inspection. Among the 12 acute metastatic cases, this varied from 1 to 7 laminae with an average length of 4.3 bony segments. The 6 acute osteomyelitic lesions ranged within the narrower limits of 2 to 5 laminae, but, of more importance, they averaged only 2.8 segments. There is, then, less tendency for the osteomyelitic cases to spread axially within the epidural space. Their extensions beyond this compartment also differ from those of the metastatic cases both as to direction and as to type.

In acute osteomyelitic lesions, extensions beyond the epidural space were confined to ventrally placed sequestra (Case 14), frank pus issuing from an underlying paravertebral abscess (Case 18) and supuration of a lamina (Case 15). The last case was the only 1 of the entire series of 20 patients in which laminar involvement was either suspected at the time of operation or subsequently proved by biopsy or x-ray study. The other acute osteomyelitic cases had disease of the vertebral bodies only. This was detected by preoperative roentgenographic examination in Cases 13, 14 and 18. The preoperative study in Case 17 was reported as uninterpretable, but caries was confirmed by biopsy and by postoperative x-ray examination. In Case 16 the epidural extension provoked neurologic trouble so suddenly (on the third day) as to preclude the preoperative roentgenographic demonstration of caries. Laminar biopsy was likewise nonconfirmatory, but postoperative x-ray study revealed caries of two cervical centra.

In acute metastatic cases, extensions beyond the epidural compartment were of quite a different nature. Pus often burrowed dorsally through the yellow ligaments to dissect along intermuscular planes (Cases 4, 5, 8, 9 and 10) or even to penetrate the lumbodorsal fascia and attain a subcutaneous position (Case 11). In no case was a ventral extension found, nor was caries demonstrated by biopsy or by roentgenographic studies in either the preoperative or the postoperative periods. Admittedly, as some<sup>6</sup> contend, this might have been overlooked, but an intensified search during recent years has failed to establish an osteomyelitic basis for an increased percentage of cases in this clinic. Moreover, there are clinical and prognostic differences yet to be added to those of age incidence and pathology that appear, collectively, to warrant adherence to the old practice of distinguishing between metastatic and osteomyelitic syndromes.

Of more interest, however, is the effect of epidural sepsis upon the underlying neural elements. So tough is the dura that its penetration by bacteria was not achieved in any of the present cases although some of them had woefully belated treatment.

Penetration of the dura is said to occur,<sup>2</sup> but it is so rare that, upon the whole, the paralyzing effects of these lesions are to be accounted for by extradural phenomena.

In most discussions, the paralyses are ascribed either to mechanical compression or to some vaguely defined alteration in the blood supply of the neural tissue. Compression is the most obvious mechanism to invoke because the lesions are space-occupying. This explanation has not been universally accepted, however, because there are those who believe that the neurologic damage inflicted by an acute epidural infection is sometimes out of all proportion to the pressure it exerts. Also, it has been remarked that neural tissue appears less able to withstand the compressive action of inflammatory masses than that of noninflammatory lesions such as spinal tumor and cyst, the changes provoked by the former seem to be more abrupt in onset, more rapid in progression and less readily reversible. It is possible that any such apparent differences in tolerance can be explained away by variations in the amounts of pressure exerted by inflammatory and noninflammatory masses respectively, by dissimilarities in their respective rates of pressure increment or by inequalities in the axial extent (or area) of their application. Nonetheless, many surgeons have felt the need for a mechanism other than simple compression to explain the neurologic features of spinal epidural sepsis.

To meet this need, most authors postulate a blood-circulatory disturbance, but only Browder et al.<sup>6</sup> provide a specific illustration of such a mechanism. They present a specimen from a fatal case in which epidural arterial thromboses are seen in conjunction with myelomalacia. Hassin<sup>7</sup> made a detailed study of another fatal case and concluded that in his patient the fault lay in a stagnation of the spinal fluid although the pathologic picture was otherwise similar to that created by simple compression.

It is obvious that more and critical observations are needed to clarify this issue. It is my impression that the compressive action of these lesions, like that of noninflammatory masses, may harm neural tissue directly, or indirectly either by impairing its intrinsic circulation or through a pressure occlusion of epidural blood vessels, especially veins. A slowing of the blood flow in vessels surrounded by purulence would pave the way for thromboses and permanent neurologic damage. In this way, the action of inflammatory lesions might indeed be found to differ from that of noninflammatory masses.

#### CLINICAL SYNDROMES AND DIFFERENTIAL DIAGNOSES

Spinal epidural sepsis produces clinical syndromes that differ from one another not only in tempo but also in their respective epiphenomena. There is,

however, a basic clinical pattern common to all variants, it consists of the following march of events

Phase I	Spinal ache	
Phase II	Root pain	
Phase III	Weaknesses of	{ voluntary muscles sphincters sensibilities
Phase IV	Paralyses	

In acute cases, the epiphenomena, in the form of signs and symptoms of unrestrained sepsis, may mask this basic pattern, but it is always present and requires only to be considered and inquired into. Also shared by all syndromes is the characteristic total (or but slightly subtotal) subarachnoidal block of the spinal fluid. If the spinal needle does not encounter epidural pus and thereby terminate the procedure at this depth, it finds yellowish spinal fluid showing a high protein content, usually a few white cells, but neither chemical nor bacteriologic evidence of leptomeningitis.

Details of the clinical data in this series of cases are given in Table 1. The broad features of the several syndromes may profitably be summarized around parenthetical comments upon frequent errors in diagnosis.

#### *Acute Metastatic Syndrome*

This illness (an obviously septic disorder) begins with an aching pain at the affected level of the spine. The pain soon becomes more severe and may bring the patient to his doctor within twenty-four hours. At this stage, fever and localized tenderness over the spine may be the only signs, but suspicion should be aroused if the history uncovers an extraspinal focus of chronic infection, recent injury to the spine or a chill (42 per cent of cases). Too often the case is dismissed as one of lumbago, arthritis, grippe or traumatic strain without provision for adequate follow-up care.

In most cases, however, the physician is first consulted on the second or third day of the illness when Phase II of the syndrome begins with root pains radiating from the now exquisitely tender spinal segment. These symptoms are sometimes construed as those of an acute "neuritis" even though the severity of the attending malaise, fever, tachycardia and leukocytosis (average white-cell count 15,600) is clearly inconsistent with this diagnosis. Although palsies are still wanting, the occasionally proffered diagnosis of acute arthritis is untenable because headache (25 per cent of cases), stiffness of the neck (58 per cent of cases) and reflex changes compatible with the anatomic level of the lesion—that is, depression of the deep tendon reflexes if it overles the cauda equina, or heightening of them if over the spinal cord—are sufficiently evident in some combination to direct attention toward the central nervous system and to indicate the need for

diagnostic spinal puncture. *By this procedure the correct diagnosis can and should be made before the end of Phase II of this syndrome.* It must be emphasized that this maneuver is safe only if undertaken by one who is both technically skillful and fully acquainted with the gross pathology of the suspected lesion. Otherwise, infection may inadvertently be carried from the epidural into the subdural or the subarachnoidal space, or both. In proper hands, however, the procedure incurs no risk that is not fully vindicated by the penalties of procrastination. In general, there is no more justification for the diagnosis of this disorder to await the appearance of paralyses than for the diagnosis of brain tumor to await coma.

If still untreated, the disease enters Phase III, in which motor weaknesses, gradually ascending numbness and impaired control over bladder or bowel supervene either concurrently or in any sequence. All the general signs of infection are intensified, the spinal ache becomes excruciating, and nuchal rigidity is apt to be extreme. At this stage, the usual mistakes are those of diagnosing leptomeningitis, poliomyelitis or infectious polyneuritis. The palsies should suffice to exclude meningitis, sensory defects and localized spinal tenderness should exclude poliomyelitis just as the latter finding is entirely out of keeping with polyneuritis. However, all doubt can be dispelled by spinal puncture because none of these diseases cause the block or the spinal-fluid formula characteristic of epidural sepsis.

If further neglected, the illness rapidly enters upon Phase IV, in which complete paralyses are conjoined with toxic prostration and even local tumor, *rubor et calor* if pus has attained a subcutaneous position. Such a state of affairs or even death itself may be reached within as few as six days. Occasionally, transition from Phase II to Phase III is delayed several days or even longer than a week, but passage from the latter to the paralytic stage is always rapid.

#### *Acute Osteomyelitic Syndrome*

As a general rule, this illness (an obviously septic disorder) differs clinically from the metastatic syndrome in only two respects: transition from Phase I to Phase II is delayed several days or even a few weeks—once Phase II is reached, however, the illness progresses with great rapidity, and vertebral caries is usually demonstrable by x-ray examination. Occasionally, the epidural extension from the caries arises very early (as in Case 16), bony changes cannot be shown by preoperative x-ray studies, and the illness appears to be metastatic until biopsy or postoperative roentgenographic examination proves it otherwise.

Differential diagnosis in the most acute cases is as outlined for the metastatic syndrome with one additional consideration. Acute vertebral osteomyelitis, uncomplicated by an epidural extension,

simulates Phase I of the syndrome under discussion. Development of an epidural extension is said to be quite infrequent,<sup>9</sup> but it must be given serious contemplation if root pains appear. A careful neurologic base-line is drawn at once, and the subsequent appearance of reflex alterations, paresthesias, weakness of the limbs or impaired functioning of the bladder calls for diagnostic spinal puncture, which *clarifies the issue immediately*.

Usually, however, the disease unfolds at a slower rate and roentgenographic changes in the spine make it necessary to consider tuberculosis. The epiphenomena of sepsis serve to exclude neoplasia, in most cases they are too intense even for the lesions of Hodgkin's disease. More trouble is afforded by tuberculosis because the staphylococcal lesions may also destroy intervertebral disks (as in Cases 13 and 14) and thus render roentgenographic appraisal of the bony lesion quite uncertain. Of most help in this connection are family history, pre-existing pulmonary symptoms, chest x-ray films and the usually more insidious development of the tuberculous lesions.

### Chronic Syndromes

These illnesses (seemingly nonseptic disorders) differ from the foregoing syndromes not merely in that the march of events is strung out over weeks or months, the epiphenomena of sepsis are entirely lacking. The spinal ache is much less severe than that in acute lesions, and the entire picture of a chronic metastatic case is consistent with the development of a primary spinal tumor. In chronic osteomyelitic cases, however, the bony changes seen on x-ray study necessitate consideration of both tuberculosis and metastatic neoplasia. Final diagnosis may have to await biopsy, which is usually forthcoming before the advent of Phase IV because this disorder is seldom confused with non-surgical ailments.

### Initial Diagnosis

Table 1 lists the diagnoses entertained by the first attending physician in each case of this series. Specific mention should probably be made of the fact that in this clinic diagnostic spinal puncture in suspected cases of spinal epidural sepsis has never excited a leptomeningitis.

### TREATMENT

In 1926, after a review of this entire subject, Dandy<sup>4</sup> summarized the incontrovertible evidence that chronic lesions are curable by surgery.

However, with the evidence then at hand, Dandy could only conjecture regarding the efficacy of operation for acute cases. He emphasized that the only 2 survivors among the 25 cases reported had been surgically drained, whereas the others had been paralyzed within forty-eight hours after the onset of neurologic changes, and had succumbed

within six to thirty days. Neither of the survivors<sup>10, 11</sup> made full neurologic recovery, but Dandy prophesied that results would depend upon the stage of the illness in which operation was undertaken.

During the next several years, sporadic reports of the surgical cure of acute cases began to appear so that by 1934 Slaughter, Fremont-Smith and Munro<sup>1</sup> were able to cite 6 survivors, including several neurologic recoveries to which they added 1 of their own (Case 1, of this series). This case was the first in which diagnosis and treatment were completed during a preparalytic phase of the illness. It typifies the possible but still rarely realized ideal management to which may now be added the adjunct of modern antibacterial agents.

Rare cases of recovery from presumed spinal epidural sepsis without operation were reported<sup>12, 13</sup> more than two decades ago, but the diagnoses in these cases are, in my opinion, open to considerable question.\* The conception of nonoperative management is mentioned only to be condemned, notwithstanding a recent suggestion<sup>16</sup> that penicillin might sometimes obviate the need for surgery. I join Grant<sup>3</sup> in strenuous protest against any idea of surgical temporization with these lesions.

Once the diagnosis is made, laminectomy for drainage of the epidural space becomes a true surgical emergency. Every care, of course, is exercised to preserve the integrity of the dura. The lesion should be cultured, and a gram preparation of an epidural specimen should be made at once for tentative chemotherapeutic guidance. Administration of sulfadiazine and penicillin is begun while the patient is being prepared for operation, and a catheter is fixed in the wound for topical instillation of the penicillin during the immediate postoperative period. After the first forty-eight hours, the wound is dressed daily with scrupulous aseptic technic, care being taken to prevent pocketing or premature closure by gently lavaging penicillin-soaked sponges to the very floor of the incision. Daily wound cultures should be made for immediate detection of any secondary invaders that might require alteration of the topically applied antibacterial agent. Results of the original wound culture may occasionally necessitate a change of all antibacterial agents, but unless an obvious primary focus is known to be other than a *Staph aureus* infection, it is safest to assume at the outset that this is the offending organism.

If the primary focus is active it should be cultured and treated by appropriate means but only after spinal drainage has been instituted.

Since the advent of penicillin and the sulfonamides, I have made delayed closure of these lami-

\*Campbell<sup>14</sup> says that von Leyden and Nonne also have reported non-operative recoveries, but he does not give the specific references. Von Leyden<sup>15</sup> does not mention such a case in his comprehensive monograph on diseases of the spinal cord, and I have been unable to locate Nonne's case. Nonne<sup>16</sup> in reporting a fatal case of otogenic origin does mention having witnessed a recovery, but this patient had had the benefit of surgical drainage. The case is undated, but it must be among the very first of surgical cures.

nectomy wounds to minimize morbidity. This is undertaken only after the patient's temperature, white-cell count and sedimentation rate are returned to normal, and the wound itself has satisfied certain criteria—namely, a full lining of clean granulation tissue, a low population of culturable bacteria and freedom from sinuses that yield pus when deep pressure is applied to the paraspinous musculature. The technical details for closure of these contaminated but noninfected wounds is beyond the scope of this paper. Suffice it to say that there have been no disruptions, and the total morbidity for metastatic cases has been reduced to an average of thirty-five hospital days in the last 3 cases. By contrast, closure of osteomyelitic wounds cannot be undertaken as early because of the more prolonged purulent drainage from the depths of the incision near the bony lesion.

When the wound is healed, patients with metastatic cases enjoying neurologic recovery are ready

folds at a leisurely pace that almost assures the patient of operation before paralysis is complete or neurologic damage irreversible. The advent of modern antibacterial agents has made little change in the outlook because these patients never present the picture of unbridled sepsis.

The prognosis for acute cases has always been quite different, regarding both life and neurologic function. This is shown in Table 2, where the end-results of 158 acute cases are aligned both for comparison by decades, and for contrast with the fate of 44 patients suffering subacute or chronic lesions. Grant<sup>2</sup> attributes the improved results of the past decade to earlier treatment made possible by publications designed to acquaint the medical profession with the urgency of these cases. That early diagnosis is the key to neurologic recovery is borne out by the present series, in which *total recovery was realized in all patients who had no paralysis at the time of operation or who had a paresis of fewer*

for discharge and immediate return to work. No support for the spine is necessary even though as many as 7 laminae have been removed, assuming of course that the articular facets were, as is proper, undisturbed by surgery. Convalescence of osteomyelitic cases is more prolonged, and it is advocated that a spinal support be worn until there is x-ray evidence to confirm a clinical impression that the spine is healed and stable.

The extensive program necessary for rehabilitation of patients who are left paraplegic lies outside the present discussion.

PROGNOSIS AND RESULTS

Since the dawn of neurosurgery the prognosis for chronic cases has been good (Table 2). Although frequently operated on under the mistaken diagnosis of spinal tumor, the great majority of these patients have lived to enjoy neurologic recovery. This is understandable because the syndrome un-

than thirty-six hours' duration. By contrast, no patient whose paralysis had been present longer than forty-eight hours made a neurologic recovery, and it was among cases of this type that all deaths occurred.

The present material indicates, however, that the prognosis for life in acute cases has been materially improved since the arrival of penicillin and the sulfonamides (Table 3). Prior to 1939, there were 3 deaths among 8 cases. The patient in Case 7 succumbed on the ninth postoperative day in uremia with pneumonia and would probably be lost even today because of the renal failure. On the other hand, the 2 patients (Cases 2 and 13) who succumbed on the eighteenth and fourteenth postoperative days of pneumonia and pneumonia with lung abscess, respectively, might have fared better had potent antibacterial preparations been available. Since 1939, the single death among 10 patients was the patient in Case 14, who died in

uremia with pneumonia and a persistent bacteremia on the thirteenth postoperative day. Concurrently, however, penicillin and sulfadiazine were probably responsible for the survivals in Cases 15 and 18—patients who suffered septic complications analogous to those proving fatal in Cases 2 and 13.

One further point concerning prognosis is worthy of note. I have maintained a distinction between metastatic and osteomyelitic cases on the grounds of dissimilarities of age incidence, pathogenesis, pathology and clinical features. Equally apparent are wide differences in their respective end results (Table 4).

### SUMMARY AND CONCLUSIONS

Nontuberculous spinal epidural infections are infrequent disorders that usually occur in patients who harbor a focus of chronic infection somewhere outside the epidural space. Among such foci, acne, furunculosis, cellulitis, vertebral caries and old

TABLE 3 *Effect of Penicillin and Sulfonamides upon Mortality in Acute Cases at the Boston City Hospital*

PERIOD	TOTAL CASES	DEATHS	SURVIVALS

After 1939	10	10	90

operative sites (sometimes apparently healed) are the most frequent. The symptomatology regularly unfolds in 4 steps:

- Phase I Spinal ache
- Phase II Root pain
- Phase III Weaknesses of  $\left\{ \begin{array}{l} \text{voluntary muscle} \\ \text{sphincters} \\ \text{sensibilities} \end{array} \right.$
- Phase IV Paralysis

When this syndrome develops over the course of weeks or months and is unattended by the signs or symptoms of infection, the case is designated "chronic." When it is compressed into a few days or a week of illness that is further marked by chills, fever, malaise, headache, stiff neck and leukocytosis, it is designated "acute." In either event, properly executed spinal puncture during (or after) Phase II establishes the diagnosis by yielding either epidural pus or a subarachnoidal block with yellowish spinal fluid that exhibits an elevated protein content, usually a few white cells, but neither chemical nor bacteriologic evidence of leptomeningitis.

Treatment is primarily surgical and consists of immediate laminectomy for drainage of the epidural space. Penicillin and the sulfonamides are valuable adjuncts.

Total recovery depends upon early diagnosis and prompt surgical intervention. If operation is done before paralysis is established, the outlook is good. After forty-eight hours of paralysis, operation may save life but the neurologic damage is probably irreparable. Prognosis for life is further dependent upon the curability of the primary focus and any

TABLE 4 *Comparative End Results of Acute Metastatic and Osteomyelitic Cases at the Boston City Hospital*

OUTCOME	METASTATIC CASES		OSTEOMYELITIC CASES

Neurologic recovery		67		17

additional septic complications. If the former is an osteomyelitis the outlook is more guarded than otherwise.

Delay in diagnosing epidural sepsis is more often attributable to a failure to give it consideration than to any other cause. Fear of performing diagnostic spinal puncture in questionable cases is seldom a factor in delayed recognition of the disease, nor should it be. This procedure is of crucial importance to early diagnosis, and in proper hands its performance is infinitely less risky than its omission.

Bad results are usually traceable to the mistaking of these disorders for more everyday ailments until paralysis is complete and neurologic damage irreversible. Experience shows that the acute infections are almost routinely confused with meningitis, poliomyelitis, infectious polyneuritis, ethanolic polyneuritis, nonspecific monoradicular neuritis, arthritis, uncomplicated osteomyelitis of the spine or even hysteria (Cases 6 and 8).

The etiologic, pathologic, clinical, therapeutic and prognostic aspects of nontuberculous spinal epidural infections are discussed in the light of experience gathered in the definitive treatment of 20 consecutive cases on the Neurosurgical Service of the Boston City Hospital between the years 1930 and 1948. It is hoped that this discussion will enhance the general understanding of these disorders, facilitate their earlier recognition and thus further reduce the incidence of poor therapeutic results.

nectomy wounds to minimize morbidity. This is undertaken only after the patient's temperature, white-cell count and sedimentation rate are returned to normal, and the wound itself has satisfied certain criteria—namely, a full lining of clean granulation tissue, a low population of culturable bacteria and freedom from sinuses that yield pus when deep pressure is applied to the paraspinous musculature. The technical details for closure of these contaminated but noninfected wounds is beyond the scope of this paper. Suffice it to say that there have been no disruptions, and the total morbidity for metastatic cases has been reduced to an average of thirty-five hospital days in the last 3 cases. By contrast, closure of osteomyelitic wounds cannot be undertaken as early because of the more prolonged purulent drainage from the depths of the incision near the bony lesion.

When the wound is healed, patients with metastatic cases enjoying neurologic recovery are ready

folds at a leisurely pace that almost assures the patient of operation before paralysis is complete or neurologic damage irreversible. The advent of modern antibacterial agents has made little change in the outlook because these patients never present the picture of unbridled sepsis.

The prognosis for acute cases has always been quite different, regarding both life and neurologic function. This is shown in Table 2, where the end-results of 158 acute cases are aligned both for comparison by decades, and for contrast with the fate of 44 patients suffering subacute or chronic lesions. Grant<sup>3</sup> attributes the improved results of the past decade to earlier treatment made possible by publications designed to acquaint the medical profession with the urgency of these cases. That early diagnosis is the key to neurologic recovery is borne out by the present series, in which *total recovery was realized in all patients who had no paralysis at the time of operation or who had a paresis of fewer*

for discharge and immediate return to work. No support for the spine is necessary even though as many as 7 laminae have been removed, assuming of course that the articular facets were, as is proper, undisturbed by surgery. Convalescence of osteomyelitic cases is more prolonged, and it is advocated that a spinal support be worn until there is x-ray evidence to confirm a clinical impression that the spine is healed and stable.

The extensive program necessary for rehabilitation of patients who are left paraplegic lies outside the present discussion.

### PROGNOSIS AND RESULTS

Since the dawn of neurosurgery the prognosis for chronic cases has been good (Table 2). Although frequently operated on under the mistaken diagnosis of spinal tumor, the great majority of these patients have lived to enjoy neurologic recovery. This is understandable because the syndrome un-

than thirty-six hours' duration. By contrast, no patient whose paralysis had been present longer than forty-eight hours made a neurologic recovery, and it was among cases of this type that all deaths occurred.

The present material indicates, however, that the prognosis for life in acute cases has been materially improved since the arrival of penicillin and the sulfonamides (Table 3). Prior to 1939, there were 3 deaths among 8 cases. The patient in Case 7 succumbed on the ninth postoperative day in uremia with pneumonia and would probably be lost even today because of the renal failure. On the other hand, the 2 patients (Cases 2 and 13) who succumbed on the eighteenth and fourteenth postoperative days of pneumonia and pneumonia with lung abscess, respectively, might have fared better had potent antibacterial preparations been available. Since 1939, the single death among 10 patients was the patient in Case 14, who died in

uremia with pneumonia and a persistent bacteremia on the thirteenth postoperative day. Concurrently, however, penicillin and sulfadiazine were probably responsible for the survivals in Cases 15 and 18—patients who suffered septic complications analogous to those proving fatal in Cases 2 and 13.

One further point concerning prognosis is worthy of note. I have maintained a distinction between metastatic and osteomyelitic cases on the grounds of dissimilarities of age incidence, pathogenesis, pathology and clinical features. Equally apparent are wide differences in their respective end results (Table 4).

### SUMMARY AND CONCLUSIONS

Nontuberculous spinal epidural infections are infrequent disorders that usually occur in patients who harbor a focus of chronic infection somewhere outside the epidural space. Among such foci, acne, furunculosis, cellulitis, vertebral caries and old

TABLE 3 *Effect of Penicillin and Sulfonamides upon Mortality in Acute Cases at the Boston City Hospital*

PERIOD	TOTAL CASES	DEATHS	SURVIVALS

After 1939	10	10	90

operative sites (sometimes apparently healed) are the most frequent. The symptomatology regularly unfolds in 4 steps:

- Phase I Spinal ache
- Phase II Root pain
- Phase III Weaknesses of  $\left\{ \begin{array}{l} \text{voluntary muscle} \\ \text{sphincters} \\ \text{sensibilities} \end{array} \right.$
- Phase IV Paralyzes

When this syndrome develops over the course of weeks or months and is unattended by the signs or symptoms of infection, the case is designated "chronic." When it is compressed into a few days or a week of illness that is further marked by chills, fever, malaise, headache, stiff neck and leukocytosis, it is designated "acute." In either event, properly executed spinal puncture during (or after) Phase II establishes the diagnosis by yielding either epidural pus or a subarachnoidal block with yellowish spinal fluid that exhibits an elevated protein content, usually a few white cells, but neither chemical nor bacteriologic evidence of leptomeningitis.

Treatment is primarily surgical and consists of immediate laminectomy for drainage of the epidural space. Penicillin and the sulfonamides are valuable adjuncts.

Total recovery depends upon early diagnosis and prompt surgical intervention. If operation is done before paralysis is established, the outlook is good. After forty-eight hours of paralysis, operation may save life but the neurologic damage is probably irreparable. Prognosis for life is further dependent upon the curability of the primary focus and any

TABLE 4 *Comparative End Results of Acute Metastatic and Osteomyelitic Cases at the Boston City Hospital*

OUTCOME	METASTATIC CASES		OSTEOMYELITIC CASES	
	NO	PER CENTAGE	NO	PER CENTAGE
Deaths	12	17	6	33
Survivals		83		67
Patient paralyzed		17		50
Neurologic recovery		67		17

additional septic complications. If the former is an osteomyelitis, the outlook is more guarded than otherwise.

Delay in diagnosing epidural sepsis is more often attributable to a failure to give it consideration than to any other cause. Fear of performing diagnostic spinal puncture in questionable cases is seldom a factor in delayed recognition of the disease, nor should it be. This procedure is of crucial importance to early diagnosis, and in proper hands its performance is infinitely less risky than its omission.

Bad results are usually traceable to the mistaking of these disorders for more everyday ailments until paralysis is complete and neurologic damage irreversible. Experience shows that the acute infections are almost routinely confused with meningitis, poliomyelitis, infectious polyneuritis, ethanolic polyneuritis, nonspecific monoradicular neuritis, arthritis, uncomplicated osteomyelitis of the spine or even hysteria (Cases 6 and 8).

The etiologic, pathologic, clinical, therapeutic and prognostic aspects of nontuberculous spinal epidural infections are discussed in the light of experience gathered in the definitive treatment of 20 consecutive cases on the Neurosurgical Service of the Boston City Hospital between the years 1930 and 1948. It is hoped that this discussion will enhance the general understanding of these disorders, facilitate their earlier recognition and thus further reduce the incidence of poor therapeutic results.

## PROGRESS IN GROUP PSYCHOTHERAPY

### A Summary of the Literature

WILLIAM B. TERHUNE, M.D.,\* AND JAMES R. DICKENSON, M.D.†

NEW CANAAN, CONNECTICUT

GROUP psychotherapy has aroused much interest in psychiatric and general medical circles. The literature is voluminous and varied, indicating many approaches and as many purposes, with coincident confusion. This report summarizes the recent literature. Medical group psychotherapy was initiated in Boston in 1905 by Dr. Joseph H. Pratt. Psychiatric group therapy has been practiced in the Boston Dispensary since 1930.

Military necessity and a shortage of psychiatric personnel resulted in the employment of this form of treatment by the armed forces in World War II. At the same time its use became expedient in civilian mental hospitals. Results indicate the need for a continuing exploration of group psychotherapy inasmuch as it is a valuable adjunct to individual psychotherapy.

In military group therapy, methods differed depending on the time and place, the facilities, the severity of illness and the therapist. There was, however, a general plan of treatment. Didactic subject matter used was analogous and usually was what the particular psychiatrist would have given patients in individual interviews. Emphasis was laid upon the normalcy of fear, aggression, projection and hostility to authority. Catharsis was employed for the relief of emotional tension and identification with others of similar experiences.

Participation in the group varied from compulsory disciplined attendance to "leaderless groups," in which patients selected their leader from their members and planned their program. The psychiatrist served as teacher-physician until the group attained sufficient knowledge of their problems and mental mechanisms to act more independently and until they had gained sufficient esprit de corps to do so. Activities were limited, but interesting

and useful projects helped group solidarity and hastened recovery. In some cases therapists distinguished between treating individuals *in a group* and *true group psychotherapy*, in which treatment is largely through the interaction of members of the group upon each other. The average period of treatment was from six to eight weeks.

Psychiatrists employing group psychotherapy treated hundreds of thousands of men, usually with only one or two individual interviews. There was little follow-up study, and return to duty terminated treatment. Many reported "cures" were not permanent, and although symptoms were temporarily alleviated, the underlying personality structure remained unchanged. The limited number of psychiatrists made adequate treatment impossible.

Group psychotherapy is being extensively used by the Veterans Administration in both their hospitals and outpatient clinics; it is being employed in some state and a few private mental hospitals. The general opinion to date is that it is not nearly so effective as individual therapy, but that it is a useful adjunct to the latter. It enables a few doctors to give a large number of patients attention that they would not otherwise receive. It helps people, it certainly does not cure them. Group therapy, or therapy carried out in groups, seems to get patients just so far, but fails to take them across the line to a final and permanent recovery.

A review of current literature indicates the following tentative conclusions:

Group psychotherapy can extend aid to a larger number of patients than individual psychotherapy alone.

Over and above the questions of expediency, the shorter period of treatment and lessened expense, group psychotherapy offers in some cases fundamental values not obtainable through individual treatment alone.

\*Associate clinical professor of psychiatry, Yale University School of Medicine; medical director, Silver Hill Foundation for the Treatment of the Psychoneuroses.

†Associate physician, Silver Hill Foundation for the Treatment of the Psychoneuroses.

This method is particularly applicable to psychoneurotics and to patients who, as children, felt rejected by the family group and who have not subsequently adapted themselves to other social groups.

Individual psychotherapy does not always solve the difficulty of the neurotic. The therapeutic group offers an opportunity to practice adaptation in a social milieu.

#### NATURE OF GROUP PSYCHOTHERAPY

Group psychotherapy involves more than an assemblage of persons with similar aims and problems. Nor does leadership of a psychiatrist in itself constitute group psychotherapy. When the therapist directs treatment toward a particular patient among several this is psychotherapy *in a group*. The relation is between therapist and patient, the selected patient benefits by identification with the leader and his support, but not through sharing group interaction. This is in contrast to psychotherapy *through* a group — the true group psychotherapy, here the interaction of the group, the psychologic effect of members upon each other, is the therapeutic agent. There is considerable difference in the technics involved and in the benefits received.

The neurotic person avoids social groups, fears criticism and is afraid to exchange his isolation for social satisfactions of which he cannot be sure. In a well conducted therapeutic group patients gain security through their acceptance by the leader and other members of the group. The therapist often represents the good parent, consistent, understanding and nonpunitive. As the members become used to one another he withdraws, throwing them more and more upon each other, deflecting their dependence from himself to the group. Emphasis is placed upon constructive achievement and emotional maturation. The group becomes a substitute for lack of gratification in early life.

Accessory technics and settings vary with the patients, their ages and their problems. Groups should be small, usually not more than seven or eight members. The room, the therapist and the time of meeting should remain the same, these constant elements affording a sense of security.

#### TYPES OF GROUP PSYCHOTHERAPY

The method employed by the psychotherapist depends directly upon his orientation. The Freudian analytic method, with loosening of repression and the conscious recognition of asocial desires, has as its aim the freeing of energy bound in needless repression. The patient is expected to find his own social outlets. This method is used by Schilder and members of his school. Schilder believes that the patient must gain insight into social and psychosexual adjustment and into premature solutions that were formed in childhood. His outpatient

group therapy makes patients realize that thoughts that they have allowed to isolate them are similar to the thoughts of others. The patients' autobiographies are read and discussed by the group, the patient having the benefit of their interpretation as well as that of the therapist. The objective of treatment is to bring the patient to mature adult development.

At the opposite end of the scale is the inspirational method, which relies to a large extent upon suggestion and the contagion of useful emotions. The patient is urged to control his behavior, to suppress asocial and harmful thoughts, and to find inspiration in religion and life work. This method is utilized by many religious groups and by Alcoholics Anonymous.

Between the analytic and the inspirational types of group therapy is a third, which employs the best elements from each, utilizing both conscious and unconscious mechanisms. Through re-education the patient is helped to understand his problems. A corrective, stabilized life is instituted, and personality reintegration is effected.

#### DYNAMICS

Group psychotherapy offers values not available through individual treatment alone, and has inherent merits dependent upon specific factors.

The family is a social and emotional unit in which the child is dependent and submissive, or else rebellious toward the authority of parents — this is often complicated by sibling rivalry. Primitive instincts must be replaced by social instincts, and in this process of personality development the group affords reassurance not always found in the home. In this group the therapist symbolizes the loving parent who does not retaliate to hostility. Emotional releases are permitted, repressed conflicts with parents and siblings may be acted out, and a new perception of self is gained.

In a psychotherapeutic group there is a fluid, changing relation. Assured of emotional support from their leader and peers, patients may test reality situations in the group without fear of reprisal. Emotional tension is released, and conflicts are resolved, with a lessening of anxiety. Insight is gained by a comparison of personal experience with the experience of others. Rejecting parents meet parents with similar problems. Persons laden with guilt find themselves no longer unique and with no further need to be isolated. Combat veterans discover the normalcy of fear.

To dispel ignorance and correct distorted attitudes, specific information is given through re-educational lectures, with varying degrees of participation by the group. Patients with tuberculosis, peptic ulcers, diabetes, heart disease and even some psychoses respond to this treatment as readily as psychoneurotics do. The force of example, seeing others with the same difficulty making a success,

is encouraging Alcoholics Anonymous employs this psychologic technic, and military groups utilize the presence of combat veterans strong in their desire to return to duty. Because of the contagion of emotion, abreaction is of limited use in a group. It has been successfully employed to remove fear through desensitization and acting out of the situation with the accompanying fears. Aggression may be released, but must be tempered, for emotionally disturbed patients react badly to displays of anger or hostility.

Guilt is dispelled, and feelings of failure lessened through the sharing of common knowledge and the common purpose of the group. Preliminary catharsis aids this function. Group purpose can be contagious, particularly when combined with the spirit of teamplay. All members must have a common goal, as those who do not sabotage the effort of the group. The group, however, must be tolerant toward the members who cannot yet enter into activities wholeheartedly.

Successful adaptation and acceptance within the group give rise to new confidence, loss of sense of inferiority and lessening of self-consciousness. Tolerance toward one's self and others is gained, with better understanding of the needs of others. Once he has attained this tolerance the neurotic learns to forgive himself and others. In the group the necessity for reasonable compromise soon becomes apparent, and such compromises become acceptable to the patient as desired results are obtained.

#### AIMS AND LIMITATIONS OF TREATMENT

Aims and limitations of treatment should be established early. These are dependent upon the training and skill of the therapist, the patient being treated and his problems and his capacities. Careful and accurate diagnosis helps to establish objectives and to indicate results that may reasonably be expected.

Catharsis is palliative and temporary. Supportive treatment—giving sympathy, understanding and some environmental manipulation—is also palliative, and is not designed to cure. Integrative treatment aims at a cure through the approach that all psychoneuroses are the result of unconscious conflict, the objective is recovery, and the therapist is the guide toward a better way of living—a balanced life.

#### THE ROLE OF THE THERAPIST

The psychotherapist must be sensitive to group reactions. In 1940 Schuler commented that the psychiatrist who uses group therapy to gratify his curiosity, feeling of superiority or sexual interests, or to receive admiration, and who is the object of the patient's sex desire is but the target for hatred and criticism in their symbolic expression of early childhood formations. His success as a therapist

depends upon his ability to understand his own tendencies to incomplete experiences and patterns of infantile reaction. Psychiatrists on the whole do not have the personality that intuitively takes to group leadership. Many enter this field of medicine with personality difficulties, conscious or unconscious. These psychiatrists tend to keep their problems secret, and therefore favor an isolated type of treatment. Secrecy of motivation is a fundamental characteristic of a neurosis, and the first step in treatment is to do away with it. In a group the physician is less authoritative, with courage gained from others the patient may challenge the physician and express hostility toward him.

A directive leader who gives a lecture, or who acts as chairman of a seminar, and who more or less controls group reaction can give information and teach the principles of re-education, but he does not contribute to group interaction, the patient identifies himself with the leader and not with the group. Too close or prolonged identification with the leader, undiluted by identification with the group, recreates the parent-child situation, and if therapy is attempted in the group it leads to rivalry among the members.

The permissive leader gradually withdraws from the group and enables the members to *re-learn* new attitudes toward authority and toward the group. He retains his importance only in the early sessions when it is necessary for him to amalgamate the group in a common purpose, this accomplished, he deflects the dependence and identification from himself to the group itself, aiding the patient in his first steps toward the socialization that is one of the prime objectives of group psychotherapy. The leader becomes less and less active in the group, as through group interaction the patient progresses toward mature adult relationships, success therein enables him to attempt with confidence to adjust to outside groups and personal relations that he has hitherto feared. When he has arrived at this point, he has no further need for the leader, and treatment may be considered a success.

#### PERSONNEL OF THE GROUP

The selection of the group is dependent on the aim, the problem of the patient and his age, as well as the training of the therapist, the time available and the setting. Group psychotherapy is designed primarily for psychoneurotics. All psychoneurotics have basic difficulties in relating themselves to others. Analysis and insight do not necessarily solve this difficulty, for the patient is left without psychologic tools, skills, practice in social adaptation or sufficient security to relate to the family in which his patterns of neurotic reaction were laid, or to the ordinary social groups in which he has never been at ease nor felt that he was accepted. As he relives his experiences as a rejected child, he needs guidance and exposure to a therapeutic group in which he can attain success before he ventures

into what are to him threatening social situations in which he feels inadequate

Through satisfying group experiences, emotionally disturbed adolescents and rejecting parents learn to deal with frustration and to find compensations and sublimations. They discover that it is more comfortable and wiser to deal with their own fear, anger and hostility, and that of others, tolerantly and with good humor. As they mature emotionally they learn to fight nobly and effectively, not primitively and unsuccessfully.

Psychopaths and psychotics are usually not treated by group therapy. If this method is to be used, they should not be included in groups made up of psychoneurotics or of patients who are only slightly disturbed.

### FUTURE GOALS

Group psychotherapy is a new type of psychiatric endeavor, experience in this field is limited, and there is much to be learned about it. Just as a very careful choice of the members of the group is required, the psychotherapist must be even more carefully chosen. Unfortunate and harmful reactions stimulated by group psychology must be held to a minimum. There has been little follow-up study, and the literature indicates that results have been too optimistically interpreted. All future reports must be carefully scrutinized. The newly organized society for the study of group psychotherapy will have a great deal to do with the stabilization and standardization of technique and the extension of new knowledge regarding this promising field.

Some of the intrinsic values of group psychotherapy have been demonstrated, and under wise leadership this contribution to mental health may be considerable. One of the outstanding merits of this form of psychotherapy is that it is practical. Small treatment units similar to those for the treatment of medical problems and for behavior problems in children may be set up throughout the country. This can be done for the psychoneurotics in general hospitals, where patients at no great cost can participate daily in group re-education. Group re-education in accordance with the Freudian technique has been given by Lazell at St. Elizabeth's Hospital with considerable success. Paroled psychotics who have recovered from acute episodes in the convalescent period can benefit from group psychotherapy in selected settings. It offers an opportunity to continue treatment on a wider scale outside an institution, to observe progress and to prevent unnecessary psychotic recurrences. It would be of inestimable value to have marital and family clinics where erroneous basic concepts could be eliminated and serious damage to personality prevented. Child-guidance clinics, with concurrent parental education, afford a natural opportunity for the organization of fathers and mothers for group psychotherapy.

### SUMMARY

The original purpose of group psychotherapy was to make treatment available to greater numbers. Its present impetus came in World War II, with extensive use in the armed forces, later in veterans' hospitals and more recently in clinics, psychiatric units and private practice.

The patient finds in the group emotional satisfactions that he was denied in childhood and has not found outside the family. Through discussion he attains a degree of desensitization and comes to realize that he is not different from others. Too close family attachments are diluted, and often he is able to make a transference from one person, upon whom he has been dependent, to a group of equals.

Group psychotherapy is particularly applicable to psychoneurotics, adolescents and rejecting parents.

Treatment is not dependent primarily upon the therapeutic relation between psychiatrist and patient, but upon interaction between members of the group. Some groups rely upon discussion and group interaction alone, but the most effective group therapy combines these with individual interviews and a twenty-four-hour daily program.

The three most widely used methods are the analytic, the inspirational and the re-educational-integration, combining the chief values of the first two methods with a definite teaching of mental-hygiene principles.

In this new form of psychotherapy overenthusiasm of therapists and noncritical evaluation of results may be detrimental to sound practice and good psychiatric technique. Group psychotherapy has demonstrated its value, not merely as a time-saver and a relatively inexpensive method of treatment but also as one that has intrinsic values not found in individual therapy alone. The patient is regarded as a social being, and in the group is given opportunity for discovering and practicing the principles of social adaptation.

## LOCAL HEALTH SERVICES IN MASSACHUSETTS

ROBERT E ARCHIBALD, M D , M P H ,\* AUTINO FIORE, M D ,† AND SOLOMON L SKVIRSKY, M D ‡

BOSTON

MASSACHUSETTS has long been recognized as a leader in many phases of public health. However, there has been a considerable lag in the provision of adequate local health facilities, owing in part to the heritage of local autonomy. Our interpretation of adequate facilities is the complete coverage of the state by local health units, conducted by the official governing body of the units and financed wholly or in part with local funds. These units should be staffed with full-time, well trained personnel rendering at least basic health services to all people of the Commonwealth. Until such local health units become a reality, a sound public-health program cannot be administered in an efficient, economic and competent manner. The primary purpose of this paper is to present a critical evaluation of existing official local health facilities in Massachusetts.

## SERVICES

Local health units should provide the six so-called minimum services recommended by Dr Haven Emerson<sup>1</sup> in his report on local health units for the nation. These include the control of communicable diseases, environmental sanitation, hygiene of maternity, infancy and childhood, including the supervision of the school child, public-health laboratory services, health information, and vital statistics. The control of chronic diseases should be added, since this is being regarded more and more as a basic health service. Actually, the activities of any given health department must fit the particular health situation of the community served. Therefore, further extension of services may include accident prevention, dental care, nutrition, mental hygiene, industrial hygiene, medical social service, housing surveys, hospital surveys and construction, and certain medical care programs. One of the most important responsibilities of the administrator of a local health unit is to set up a health program that provides maximum health benefits.

## PERSONNEL

To render necessary health services, a well trained professional staff is essential. Health departments should serve units of population of sufficient size to make possible the full-time employment of personnel. Emerson recommends that a unit serving 50,000 persons should have a staff consist-

ing of a full-time public-health physician, a full-time sanitary engineer, a sanitary inspector, 10 public-health nurses, 1 of whom should be of supervisory grade, and 3 clerical workers. This is considered basic personnel required by health units. Actually, the type and number of personnel employed will depend upon the size of the population served and the scope of the health program planned.

## STATISTICAL DATA

Massachusetts has a total population of 4,493,281 (1945 Census). Its area covers 7838.7 square miles with a density of 573.2 persons per square mile. There are 39 cities and 312 towns, with average populations of 76,577 and 4,829 respectively. Metropolitan Boston, which includes 43 communities, has 2,066,100 inhabitants, or 46 per cent of the total population.

The state is composed of 14 counties (Table 1). Community population is given in Table 2, which shows that 317 communities, representing 90.3 per cent of all the cities and towns, are inhabited by only 33.7 per cent of the total population. On the other hand, 66.3 per cent of the total population resides in only 34 or 9.7 per cent of the 351 communities.

It is evident that the bulk of the population is situated in a few communities, which for the most part should be able to provide necessary funds for adequate local health facilities and services. However, many communities with relatively small populations are economically unable to do so.

## LAWS PERTAINING TO LOCAL HEALTH UNITS

The *General Laws* (Ter Ed.) provide that every town shall elect three members of the board of health for a term of three years, if the town provides such a board; otherwise, the board of selectmen shall act as the board of health.<sup>2</sup>

In each city, the board of health shall consist of three persons appointed by the mayor, except in any city authorized to have a different type of organization by a special legislative act.<sup>3</sup> One member of the board shall be a physician. Also, provisions are made whereby a city or town may create a health department to replace the board of health, and specific procedures for making this change are outlined by law.<sup>2</sup>

It is possible for two or more towns, by vote of each, to form a district for the purpose of employing therein a health officer and necessary assistants and clerks. The law gives specific instructions for

\*Director, Division of Local Health Administration, Massachusetts Department of Public Health.

†Epidemiologist, Division of Local Health Administration, Massachusetts Department of Public Health.

‡Assistant director, Division of Local Health Administration, Massachusetts Department of Public Health.

the formation of a health district, and forbids any city to join such a union.<sup>4</sup>

Any governmental unit, including a city or town, may enter into an agreement with one or more other governmental units to perform jointly any service, activity or undertaking that each contracting unit is authorized by law to perform.<sup>5</sup>

The County of Barnstable is authorized to appoint a county health officer.<sup>6</sup> This is the only

charged primarily with the responsibility of preventing disease dangerous to the public health among the people within their jurisdiction by all reasonable and lawful methods. These methods include the carrying out of specific duties delegated to them by law and the adoption and enforcement of reasonable local rules and regulations.

Scientific advances, especially in the fields of bacteriology and immunology, and the demonstration of what may be accomplished in health promotion by the dissemination of information have greatly expanded the scope of public-health activities during recent years. Traditionally, boards of health have been thought of chiefly as exercising broad police powers through the right to license, to abate nuisances, to condemn unfit dwellings and to order personal or property quarantine. Although environmental sanitation is still very important, recent trends have brought health departments and their personnel more directly

TABLE 1 *Population and Number of Cities and Towns in Each County (Based on 1945 State Census)*

act (1906), the board of health was allowed to continue the appointment and assignment of school physicians and nurses. In some communities, local boards of health assume responsibility for medical inspection of parochial and private schools.

#### RESPONSIBILITIES OF BOARDS OF HEALTH

Every board of health must organize annually and select one of its members as chairman. They may appoint agents to act for them in cases of emergency, or if they cannot conveniently assemble. This agent will have all the authority of the board and will be directly responsible to it. The board is

TABLE 3 *Classification of Health Officers*

CLASSIFICATION OF HEALTH OFFICERS	NO OF COMMUNITIES	PER CENTAGE OF COMMUNITY IN GROUP	POPULATION OF EACH GROUP	PERCENTAGE OF POPULATION IN EACH GROUP
Full time medical health officers	10	3	1,559,052	34.7
Full time lay health officers	45	13	1,485,887	33.1
Part time medical health officers	38	11	296,928	6.6
Part time lay health officers	145	41	749,407	16.7

Totals	351		4,493,281	

in contact with individuals or groups of persons by programs in preventive medicine, diagnostic services and follow-up home visits under the direction of the family physician. Thus, a logical and necessary expansion in public-health activities has occurred.

#### LOCAL HEALTH UNITS

Independent local health units are maintained by all of the 351 communities in Massachusetts. Separate boards of health exist in 232 communities, whereas the selectmen act as such in 107 additional towns. Health departments have been established by 9 communities. The public welfare commission assumes the duties of the board in one city, and in another city the board of health and the board of charities are combined. In the town of Nantucket, which is a separate county in itself, the county commissioners also function as the board of health. A physician serves as a member of the board in but 132 communities.

Table 3 shows a grouping of communities based on a classification of health officers.

Except for established health departments all health officers derive their authority from their appointments as agents of the boards of health.

The director of a local health unit should be a full-time, medically trained health officer. Services rendered by a health unit are such that a physician trained and experienced in modern public-health practice is best qualified to serve as a director.

Table 3 reveals the lack of full-time health officers, especially in the many communities with relatively small populations. Only 34.7 per cent of the population is served by health units employing full-time medically trained health officers. The full-time nonmedical health officers, serving 33.1 per cent of the population, have made a remarkable and praiseworthy contribution to the health administration of their communities. They have demonstrated their ability to hold responsible positions in public health, and there will always be a place

for the experienced or trained nonmedical health officer. The part-time officers are handicapped by the limitations inherent in such employment, their situation does not encourage efficiency or economy.

#### *Barnstable*

A county health department, authorized by the General Court, was established in Barnstable County in 1926. Independence of the board of health of each town is maintained in that the county health officer acts as agent only for the boards of health that specifically appoint him to do so. Towns preserve their full rights of local control, and some of them employ their own agents, inspectors and nurses. Health regulations of the towns are not uniform. The county health officer is not given adequate authority, and his knowledge and experience cannot be utilized to full advantage. This type of health organization is not sound.

#### *Local District Health Units*

In 1927 legislation was passed to permit the formation of health districts by unions of towns, small communities being allowed to avail themselves of the services of an adequately staffed full-time health department. The significance of that native feeling of local self-sufficiency may be appreciated by the fact that no towns have ever taken the initiative in forming such a union. However, in 1930, under a co-operative arrangement with the Commonwealth Fund, the Massachusetts Department of Public Health began to organize two separate local health units, one of 15 towns in the Southern Berk-

shire area, and another of 14 towns in the Nashoba Valley. A difficult task was accomplished in convincing the boards of health of the need for centralizing their health activities. By 1931, the two units were established. Each unit represented a voluntary grouping of towns, for the purpose of demonstrating the advisability of co-ordinated full-time health services not obtainable by the individual communities.

The director of each unit received his legal status by being appointed agent of the constituent boards of health. The local boards did not lose their identity or relinquish any of their prerogatives. The towns could vote themselves out of the union whenever they so desired. During the years of demonstration, the Commonwealth Fund financed the project with the expectation that the communities would realize the value of such a health district, and would assume complete financial responsibility. This did not materialize in the Berkshire Unit, which ceased to function in 1940 because of insufficient funds. The director of the Nashoba Unit resigned in 1943. War-time manpower shortages made it impossible to fill the vacancy. However, the Nashoba Associated Boards of Health organized a skeleton force and continued its activities on a limited scale.

The law permitting towns to join and form health units has not met with success in Massachusetts. There are two inherent weaknesses in the law. First of all, unions of towns are usually not contained within any established governmental unit and hence are difficult to administer. Secondly, towns may withdraw from the union, thus assuring no stability to it.

A medical director assumed responsibility for the Nashoba Health Unit on July 1, 1948. In conjunction with the Harvard School of Public Health, plans have been made for the development of a public-health field-training center in this unit, which at present is composed of nine towns. It is expected that the reorganized Nashoba Unit will demonstrate to other communities a workable solution of their local health problems.

#### *Nursing Service*

Every community in Massachusetts has some public-health nursing service administered by either official or voluntary agencies or a combination of both. Voluntary agencies are included because of the direct services they render to communities. Table 4 shows the number of nurses employed by each agency. There are approximately 1379 public-health nurses in the Commonwealth exclusive of industrial nurses, whose activities are mainly limited to industry. This would give a ratio of 1 nurse to each group of 3379 residents, if the distribution of nurses were even. However, the larger cities employ the majority of these nurses—for example Boston alone has 276 nurses. Also, 44 of the school nurses are employed part time. Therefore, the

above ratio does not indicate the true nursing facilities

The 1379 nurses in Massachusetts are employed by a total of 452 agencies. There are 97 communities with school nursing service only, and 90 communities with but 1 nurse carrying on generalized nursing services. There are 123 communities with more than 4 nurses whose activities are directed by three different agencies. Only 18 communities have agencies with a full-time nursing supervisor. Thus, although some of the small communities are urgently in need of more complete nursing service, many other communities have three or more agencies employing numerous nurses whose activities are not co-ordinated, whose services often overlap and whose programs actually are at times conflicting. Poor distribution of nurses, multiplicity of employing agencies, lack of adequate nursing supervision and the shortage of properly trained nursing personnel all combine to decrease the efficiency of public-health nursing. In addition, many nurses are employed in specialized programs that limit their nursing activities. The principle of generalized public-health nursing should be adopted for greater nursing benefits and for economy. Also, communities and agencies should in some way pool their nursing resources and work together as one team.

#### *Sanitarians*

The health units of 37 communities employ full-time sanitarians, and 118 employ part-time sanitarians. In 71 communities, the agent or some other employee of the board of health, in addition to his other duties, acts as the sanitary officer. In 110 communities, the services of a sanitary officer are not available, and it is assumed that some member of the board of health acts as sanitarian when the occasion arises. The remaining 15 communities jointly employ four full-time sanitarians. Thus, only 14.6 per cent of the communities have full-time sanitary officers, and 31.3 per cent are without the services of a sanitarian. The 220 towns with a population of 5000 or less can hardly be expected to employ full-time trained sanitarians unless they decide to combine their resources, as was done by the 15 communities mentioned above.

#### *Nutritionists*

There are approximately 30 full-time and 13 part-time nutritionists in the Commonwealth. The Greater Boston area accounts for 25 full-time and 11 part-time nutritionists, and Springfield, Lowell, Lawrence, Beverly, Pittsfield and Framingham account for the remainder. All other communities must depend upon the nutritional services offered by the Department of Public Health or voluntary agencies.

#### CONCLUSIONS

Adequate facilities are not available for the provision of basic health services to all citizens of

Massachusetts. The problem especially concerns many small communities, economically unable to provide these facilities and yet reluctant to form co-operative health units for the purpose of employing a sufficient number of trained personnel.

A duty and responsibility of civil government is to provide its citizens with all benefits conducive to maximum health and well-being. In 1797, the legislature authorized each community to provide a board of health. However, with the many changes that have occurred in all aspects of living, and with the increased medical knowledge, especially in prevention of disease, most local boards are not equipped at present to render modern health services and meet all emergencies. In larger communities, health departments with greatly increased facilities have been established, and progress has been satisfactory. In small communities, expansion has been impossible for economic reasons. Permissive laws have been passed in the hope that these communities would join forces in the battle for health, but to no avail. Since these communities elected to retain their local autonomy, efficient and often necessary health services are lacking because of inadequate facilities.

Local health units, rendering direct services to the people, form the foundation of public health in the nation. Sound public-health programs can be best administered through sound local health departments, covering the entire population. On the basis of existing facilities and laws, such health units are not feasible in this state. Massachusetts needs new laws and increased facilities to keep abreast of public-health progress.

The first and most important step is the enlightenment of the public. Pertinent information must be disseminated to all citizens, whose understanding and active interest are essential in effecting the changes necessary to correct existing inadequacies. We are indeed fortunate to live in a country in which the lawmakers respond favorably to the will of the people. Therefore, those interested in health must carry on a sustained, vigorous and intensive campaign until the ultimate goal has been attained — that is, the provision through local government of a sufficient number of adequately staffed, full-time local health units, so as to make available at least minimum health services to every person in Massachusetts and over every square mile of the Commonwealth.

for the experienced or trained nonmedical health officer. The part-time officers are handicapped by the limitations inherent in such employment, their situation does not encourage efficiency or economy.

#### *Barnstable*

A county health department, authorized by the General Court, was established in Barnstable County in 1926. Independence of the board of health of each town is maintained in that the county health officer acts as agent only for the boards of health that specifically appoint him to do so. Towns preserve their full rights of local control, and some of them employ their own agents, inspectors and nurses. Health regulations of the towns are not uniform. The county health officer is not given adequate authority, and his knowledge and experience cannot be utilized to full advantage. This type of health organization is not sound.

#### *Local District Health Units*

In 1927 legislation was passed to permit the formation of health districts by unions of towns, small communities being allowed to avail themselves of the services of an adequately staffed full-time health department. The significance of that native feeling of local self-sufficiency may be appreciated by the fact that no towns have ever taken the initiative in forming such a union. However, in 1930, under a co-operative arrangement with the Commonwealth Fund, the Massachusetts Department of Public Health began to organize two separate local health units, one of 15 towns in the Southern Berk-

shire area, and another of 14 towns in the Nashoba Valley. A difficult task was accomplished in convincing the boards of health of the need for centralizing their health activities. By 1931, the two units were established. Each unit represented a voluntary grouping of towns, for the purpose of demonstrating the advisability of co-ordinated full-time health services not obtainable by the individual communities.

The director of each unit received his legal status by being appointed agent of the constituent boards of health. The local boards did not lose their identity or relinquish any of their prerogatives. The towns could vote themselves out of the union whenever they so desired. During the years of demonstration, the Commonwealth Fund financed the project with the expectation that the communities would realize the value of such a health district, and would assume complete financial responsibility. This did not materialize in the Berkshire Unit, which ceased to function in 1940 because of insufficient funds. The director of the Nashoba Unit resigned in 1943. War-time manpower shortages made it impossible to fill the vacancy. However, the Nashoba Associated Boards of Health organized a skeleton force and continued its activities on a limited scale.

The law permitting towns to join and form health units has not met with success in Massachusetts. There are two inherent weaknesses in the law. First of all, unions of towns are usually not contained within any established governmental unit and hence are difficult to administer. Secondly, towns may withdraw from the union, thus assuring no stability to it.

A medical director assumed responsibility for the Nashoba Health Unit on July 1, 1948. In conjunction with the Harvard School of Public Health, plans have been made for the development of a public-health field-training center in this unit, which at present is composed of nine towns. It is expected that the reorganized Nashoba Unit will demonstrate to other communities a workable solution of their local health problems.

#### *Nursing Service*

Every community in Massachusetts has some public-health nursing service administered by either official or voluntary agencies or a combination of both. Voluntary agencies are included because of the direct services they render to communities. Table 4 shows the number of nurses employed by each agency. There are approximately 1379 public-health nurses in the Commonwealth exclusive of industrial nurses, whose activities are mainly limited to industry. This would give a ratio of 1 nurse to each group of 3379 residents, if the distribution of nurses were even. However, the larger cities employ the majority of these nurses—for example Boston alone has 276 nurses. Also, 44 of the school nurses are employed part time. Therefore, the

toses studied, furacin in solution and soluble dressing is an effective bactericidal agent

### SENSITIZING EFFECT

In consideration of the fact that a change in the base was made, the substitution of polyethylene glycol for propylene glycol, 25 volunteers were patch tested with the newer soluble dressing and the new base for irritant properties, ten days later the same volunteers were retested for sensitizing properties. The tests were applied to the skin for forty-eight hours, and reactions were noted at twenty-four, forty-eight, seventy-two and a hundred and twenty hours. The substances were applied under a 2.5-cm-square piece of cotton fabric covered with oiled silk and fixed with adhesive tape. The first application of the dressing and soluble base resulted in no reaction at twenty-four, forty-eight, seventy-two and a hundred and twenty hours. The second application ten days later resulted in no reaction in 24 of the volunteers. One subject developed pruritus and erythema 2 cm square, after twenty-four hours, this subsided in twenty-four hours, with negative findings at seventy-two and one-hundred and twenty hours, and no desquamation at the site of either test. Twelve cases of sensitivity reaction were noted in this group of 203 cases remaining under observation. Reactions were severe local erythematous vesicular and oozing outbreaks often accompanied by generalized eczematoid dermatitis involving the face, neck, trunk and extremities. Examples of reactions and investigations are best shown by the case reports presented below.

### CASE REPORTS

**CASE 1 L C** a 26-year-old man, suffered from an infectious eczematoid dermatitis of both lower legs for 6 months despite treatment with various ointments. On October 31, 1946, he was started on furacin soluble dressing twice daily. One week later he showed considerable improvement, with the lesions drying and less crusting present. On November 19 he reported to the Clinic his local dermatitis worse and accompanied by a generalized papulovesicular eruption. Treatment was suspended, and cornstarch baths were prescribed twice daily. The patient's condition became worse despite soothing applications. On November 26 he was hospitalized with a generalized eczematous dermatitis the face and legs were edematous and covered with oozing and crusted lesions. Under continued bed rest, baths and soothing applications, the dermatitis subsided in 2 weeks. The patient refused patch tests and further investigation.

**CASE 2 J C** a 38-year-old woman had an eczematous dermatitis of 5 years' duration on the right ankle and dorsum of the foot. Examination showed an irregular infiltrated area of eczematous dermatitis 7.6 by 10.2 cm in diameter over the lateral aspect of the right ankle and dorsum of the foot with ulcerated areas covering most of the lesion. Moderate vesicles of the right leg were noted. Serologic examination of the blood was negative. Daily application of furacin soluble dressing with bandaging was instituted on January 22, 1947. It was continued with slow improvement of the dermatitis and healing of the ulcerations until February 13, when the lesions on the foot showed decided increase in erythema and oozing accompanied by a generalized papular and eczematous dermatitis. Treatment was discontinued. Cornstarch baths and soothing applications were prescribed with general clearing of the dermatitis and symptoms in 3 weeks. On March 4 the patient consented to patch testing

with the following combinations of ingredients and results: furacin powder in vaseline (0.2 per cent), negative; carbowax (1540 in vaseline), negative; furacin powder in polyethylene glycol, + + + +, carbowax (4000 in vaseline) negative; furacin base (polyethylene glycol C W 1540 and 4000), negative; furacin and carbowax (1540-4000), negative; furacin soluble dressing (whole product), + +, and polyethylene glycol doubtful.

**CASE 3 A B** a 32-year-old man gave a history of recurrent attacks of infectious eczematoid dermatitis of both legs. On January 17, 1947, he showed vesicular crusted and oozing lesions extending from the midleg to the ankles. The past history indicated a poor response to various topical medication. A patch test with furacin soluble dressing to the left deltoid area was negative at 24, 48 and 72 hours and daily

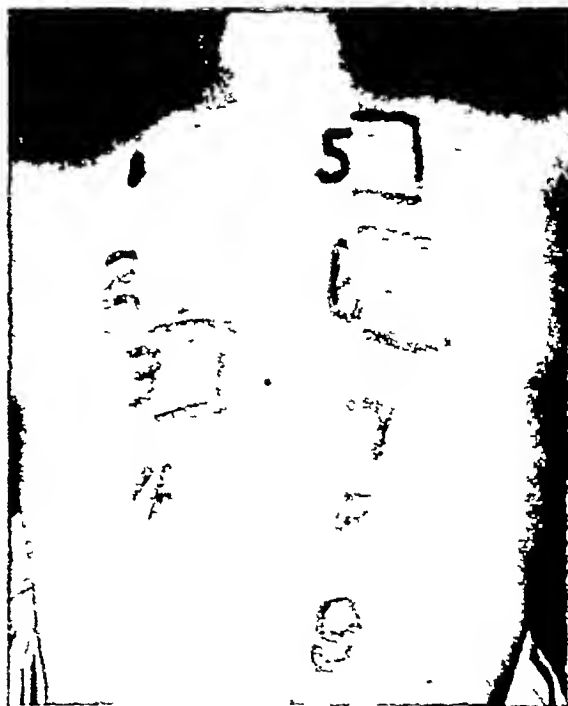

FIGURE 1 Positive Reactions in Case 3 at Sites of Furacin Soluble Dressing (3) Furacin Topical Solution (5) and Furacin Powder in Polyethylene Glycol (6)

applications of the dressing were started on January 20. Two days later the patient complained of increased burning and itching after application. Examination showed increased erythema, vesiculation and serous discharge over the involved areas. The eruption slowly improved under boric acid wet dressings and plain Lassar's paste daily. Four weeks later patch tests were performed with the various combinations of ingredients and results noted as follows: furacin powder in vaseline (0.2 per cent) negative; furacin and carbowax negative; furacin soluble dressing (whole product), +; furacin base (polyethylene glycol C W 1540 and 4000) negative; furacin topical solution + + +; furacin powder in polyethylene glycol + — —; polyethylene glycol doubtful; and carbowax (4000 in vaseline) negative. The reactions to furacin are shown in Figure 1.

**CASE 4 P M**, a 60-year-old man came to the Skin Clinic on February 20, 1947, showing on both legs eczematous lesions of 3 weeks' duration. Prior treatment had consisted of boric acid ointment and Lassar's paste without result. Treatment was instituted with furacin soluble dressing twice daily with gradual improvement and healing of the lesions.

## FURTHER STUDIES IN THE USE OF FURACIN IN DERMATOLOGY\*

JOHN GODWIN DOWNING, M D,† AND F WELLINGTON BRECKER, M D‡

BOSTON

FROM August, 1946, to September 10, 1947, 278 additional cases of dermatoses were treated with furacin (5-nitro-2-furaldehyde semicarbazone) soluble dressing and furacin solution by the Dermatologic Department of the Boston City Hospital. The diseases treated and the results obtained are presented in Table 1. It will be noted that the

contributory factor. However, 5 patients have died while under treatment with furacin compounds. Although in no case was the local medication deemed contributory, one cannot rule out the possibility of toxic effects by absorption. Therefore, it would be of extreme value if further studies were made to prove or disprove that the drug is

TABLE 1 Comparative Results in Diseases Treated

results obtained were similar to those in the original report.<sup>¶</sup> Again, the drug showed itself to be effective in the treatment of pyogenic infections—impetigo contagiosa, ecthyma and hypostatic and decubitus ulcers—and of some value in the treatment of infectious eczematoid dermatitides. However, the danger of sensitization in the latter group prohibits its extended use.

Two elderly women died while under treatment with furacin soluble dressing for decubitus ulcers. One died on the thirteenth day of therapy, and the other on the thirtieth day. They were over eighty years of age, and had been bedridden for years after multiple cerebral thromboses. Bronchopneumonia was the diagnosis at discharge in each case. Furacin soluble dressing was not considered as a

absorbed into the general circulation. In all these cases the local destruction of tissue was marked, and large amounts of medication were used.

## BACTERIOLOGY

Cultures of the bacterial flora present in the dermatoses treated were made in 59 cases before the institution of treatment. There were 124 strains of 9 species of organisms isolated. The gram-positive organisms—*Staphylococcus aureus*, *Staph. albus*, *Streptococcus haemolyticus*, *Corynebacterium diphtheriae* and diphtheroids—were found in 85.4 per cent of the total cultures. In the gram-negative group there were 10 cultures of *Pseudomonas aeruginosa*, 4 of *Proteus vulgaris* and 3 of enterococci. One case of pyoderma of the left foot showed a virulent *C. diphtheriae* growth and *Staph. albus*. A repeat culture in one week was negative for *C. diphtheriae*, and *Str. haemolyticus* was cultured. From the response noted in this group of derma-

The first application of the dressing and soluble base resulted in no reaction at twenty-four, forty-eight, seventy-two and a hundred and twenty hours. The second application ten days later resulted in no reaction in 24 of the volunteers. One subject developed pruritus and erythema, 2 cm square, after twenty-four hours, this subsided in twenty-four hours, with negative findings at seventy-two and one-hundred and twenty hours, and no desquamation at the site of either test. Twelve cases of sensitivity reaction were noted in this group of 203 cases remaining under observation. Reactions were severe local, erythematous vesicular and oozing outbreaks, often accompanied by generalized eczematoid dermatitis involving the face, neck, trunk and extremities. Examples of reactions and investigations are best shown by the case reports presented below.

### CASE REPORTS

**CASE 1 L C**, a 26-year-old man, suffered from an infectious eczematoid dermatitis of both lower legs for 6 months, despite treatment with various ointments. On October 31, 1946, he was started on furacin soluble dressing twice daily. One week later he showed considerable improvement, with the lesions drying and less crusting present. On November 19 he reported to the Clinic, his local dermatitis worse and accompanied by a generalized papulovesicular eruption. Treatment was suspended, and cornstarch baths were prescribed twice daily. The patient's condition became worse despite soothing applications. On November 26 he was hospitalized with a generalized eczematous dermatitis, the face and legs were edematous and covered with oozing and crusted lesions. Under continued bed rest baths and soothing applications, the dermatitis subsided in 2 weeks. The patient refused patch tests and further investigation.

**CASE 2 J C**, a 38-year-old woman had an eczematous dermatitis of 5 years' duration on the right ankle and dorsum of the foot. Examination showed an irregular infiltrated area of eczematous dermatitis 7.6 by 10.2 cm in diameter, over the lateral aspect of the right ankle and dorsum of the foot, with ulcerated areas covering most of the lesion. Moderate vesicles of the right leg were noted. Serologic examination of the blood was negative. Daily application of furacin soluble dressing with bandaging was instituted on January 22, 1947. It was continued with slow improvement of the dermatitis and healing of the ulcerations until February 13, when the lesions on the foot showed decided increase in erythema and oozing, accompanied by a generalized papular and eczematous dermatitis. Treatment was discontinued. Cornstarch baths and soothing applications were prescribed with general clearing of the dermatitis and symptoms in 3 weeks. On March 4 the patient consented to patch testing,

with the following combinations of ingredients and results: furacin powder in vaseline (0.2 per cent), negative; carbowax (1540 in vaseline), negative; furacin powder in polyethylene glycol, ++++, carbowax (4000 in vaseline), negative; furacin base (polyethylene glycol C W 1540 and 4000), negative; furacin and carbowax (1540-4000), negative; furacin soluble dressing (whole product), ++, and polyethylene glycol, doubtful.

**CASE 3 A B**, a 32-year-old man, gave a history of recurrent attacks of infectious eczematoid dermatitis of both legs. On January 17, 1947, he showed vesicular crusted and oozing lesions extending from the midleg to the ankles. The past history indicated a poor response to various topical medication. A patch test with furacin soluble dressing to the left deltoid area was negative at 24, 48 and 72 hours, and daily

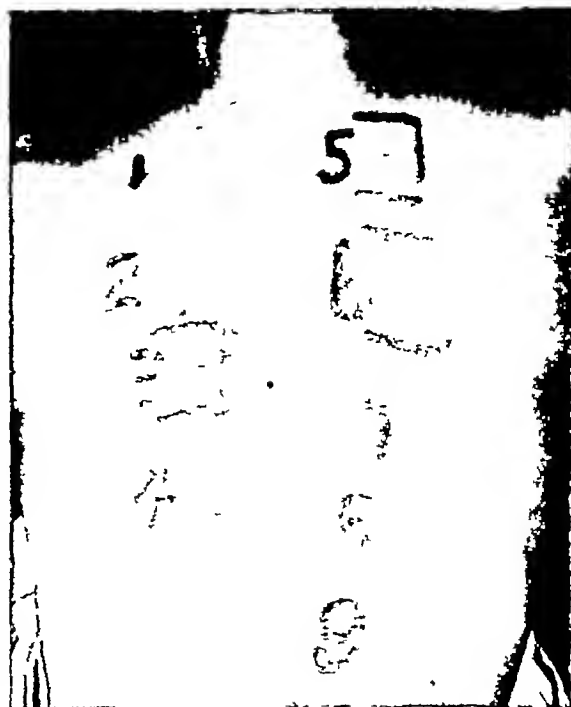

FIGURE 1 Positive Reactions in Case 3 at Sites of Furacin Soluble Dressing (3) Furacin Topical Solution (5) and Furacin Powder in Polyethylene Glycol (6)

applications of the dressing were started on January 20. Two days later the patient complained of increased burning and itching after application. Examination showed increased erythema, vesiculation and serous discharge over the involved areas. The eruption slowly improved under boric acid wet dressings and plain Lassar's paste daily. Four weeks later patch tests were performed with the various combinations of ingredients and results noted as follows: furacin powder in vaseline (0.2 per cent), negative; furacin and carbowax negative; furacin soluble dressing (whole product), +; furacin base (polyethylene glycol C W 1540 and 4000) negative; furacin topical solution, +++; furacin powder in polyethylene glycol, +; polyethylene glycol, doubtful; and carbowax (4000 in vaseline), negative. The reactions to furacin are shown in Figure 1.

**CASE 4 P M**, a 60-year-old man came to the Skin Clinic on February 20, 1947, showing on both legs eczematous lesions of 5 weeks' duration. Prior treatment had consisted of boric acid ointment and Lassar's paste without result. Treatment was instituted with furacin soluble dressings twice daily with gradual improvement and healing of the lesions.

until the 27th day, when sensitivity consisting of increased erythema, vesiculation and serous oozing developed at the sites of application. These lesions subsided in approximately 3 weeks with applications of bland ointments. Patch tests were performed with the following combinations of ingredients and results: furacin soluble dressing (whole product), ++, furacin topical solution, +++, furacin powder in polyethylene glycol, +++++, furacin base (polyethylene glycol C. W. 1540 and 4000), negative, furacin powder (0.2 per cent in C. W. 1540 and 4000), negative, furacin powder in vaseline, negative, carbowax (4000 in vaseline), negative, carbowax (1540 in vaseline), negative, and polyethylene glycol, negative.

The results in these cases strongly suggest that the sensitizing effect of the product is due to a synergistic action between the furacin powder and the polyethylene glycol present in the dressing.

### DISCUSSION

In addition to the cases reported above, the records of 30 patients treated in private practice showed similar results. In this group 2 patients became sensitized. Both were treated for a recurrence of otitis externa, after an apparent cure several months previously with furacin solution. Within forty-eight hours of reapplication of the substance there was marked erythema, vesiculation and oozing of the skin of the auricle and periauricular area. Several other cases of sensitization were seen in the office of one of us (J. G. D.), as well as in various state and federal institutions. These sensitizations were for the most part severe and disabling, necessitating hospitalization for weeks. With this increase in the number of untoward reactions, one becomes very careful and somewhat hesitant about prescribing these compounds, for it is difficult to foresee which patient will become sensitized. It is apparent that the longer the drug is used, the greater is the reaction to sensitivity.

It is believed that the number of these reactions will increase when the drug is used the second time, either for a recurrence of the previous eruption or for another pyogenic dermatosis. It might be noted in the patch tests that the furacin in addition to carbowax caused no reaction. Apparently, some chemical reaction from the combination of the polyethylene glycol and the furacin powder gives the sensitizing factor. Throughout the studies it was apparent that the best results were obtained in the use of the compounds in pyogenic infections

not sensitized — namely, impetigo contagiosa, ecthyma and otitis externa. The success of the compounds as noted by the subsequent cultures show that furacin is an effective agent in reducing infection. We therefore believe that if the element of sensitization were reduced, this drug would be of greater value in the treatment of pyogenic infections of the skin. Case 3 shows the futility of pre-treatment patch tests.

### SUMMARY

Two hundred and seventy-eight additional patients were treated at the Dermatologic Department of the Boston City Hospital with furacin (5-nitro-2-furaldehyde semicarbazone) in a soluble base and in topical solution. Two hundred and forty-five patients were treated with the product in the soluble base, and 33 with the topical solution of the product.

No noticeable difference in effectiveness in the soluble dressing and topical solution was noticed, with the possible exception of ease of application of the different products — that is, the solution was used in infectious eczematoid dermatitis in a group of cases secondary to ear infections with greater facility of application than the soluble base containing the product, whereas the soluble base seemed more satisfactory for use in ecthyma and ulcer cases.

The substitution of polyethylene glycol for propylene glycol in the product caused little or no sensitization of normal skin in a group of 25 volunteers tested.

The effectiveness of the compounds as noted by subsequent cultures showed that furacin is an effective agent in reducing infection.

Sensitization to the drug was noted in 12 out of 203 cases remaining under observation at the hospital, and in 2 out of a group of 30 cases seen in private practice, which makes over 6 per cent sensitization. This percentage is considered too high.

Sensitivity is apparently due to a synergistic action of the furacin powder and the polyethylene glycol on the abnormal skin treated.

With this high rate of sensitization, extreme care in the selection of cases and careful supervision of the patients using these compounds are recommended.

## MEDICAL PROGRESS

## CLINICAL AND PATHOLOGICAL ASPECTS OF ENCEPHALITIS\*

RAYMOND D ADAMS, M D,† AND LOUIS WEINSTEIN, M D ‡

BOSTON

A GREAT deal of confusion appears to exist in the minds of many physicians regarding the criteria necessary for the diagnosis of encephalitis. There is a common tendency on the part of clinicians to designate as encephalitis any disease in which fever and neurologic symptoms are conjoined. In the New England states and probably in many other areas of the United States this diagnosis almost invariably proves to be incorrect at autopsy. The pathologist in such cases usually turns out to be bacterial endocarditis with multiple brain emboli, tuberculosis or torulosis of the meninges, thrombophlebitis of cerebral vessels, tumor, vascular disease or abscess of the brain. Sometimes there are no demonstrable neuropathologic lesions, and by inference a diagnosis of acute "toxic" or confusional psychosis is reached. The purpose of this brief communication is therefore to present, for the use of general practitioners, some of the salient clinical and pathological features of the various types of encephalitis.

At the outset, an exact definition of *encephalitis* is required. As most generally used, this term signifies an inflammatory disease of the brain, if concomitant involvement of the brain and spinal cord exists the condition is specified as *encephalomyelitis*. Unfortunately, however, a few writers apply these names to a large variety of brain diseases of diverse etiology—some infectious and others not—hence such incongruous terms as "traumatic encephalitis" and "toxic encephalitis." The more restricted meaning is the one used in this paper. Meningitis, in the sense of an inflammatory disease confined to the pia-arachnoid membranes and subarachnoid space, is not included in the present discussion.

To obtain clarity of thought on this subject a sound classification of the various forms of encephalitis is essential. Several have been proposed, though none of them are entirely adequate. The following classification, based on etiology, if known, and otherwise on descriptive pathology, is probably the most satisfactory one available at present and

has the sanction of two eminent neuropathologists, Spielmeyer<sup>1</sup> and Greenfield<sup>2</sup>

- Encephalitis due to visible micro-organisms
  - Bacterial infections, such as focal embolic encephalomyelitis
  - Spirochetal infections such as syphilitic meningoencephalitis (general paresis)
  - Fungous infections, such as torula
  - Rickettsial disease, such as typhus
  - Parasitic infections, such as trichinosis, malaria and toxoplasmosis
- Encephalitis due to filterable viruses §
  - Encephalitis lethargica
  - St. Louis encephalitis
  - Equine encephalitis—Eastern, Western and Venezuelan types
  - Poliomyelitis
  - Herpes zoster
  - Mumps meningitis, ? encephalitis
  - Lymphocytic choriomeningitis
  - Infectious mononucleosis—probably of viral etiology
  - Herpes simplex encephalitis
  - Encephalitis with intranuclear inclusion bodies—? herpes simplex
  - Rabies
  - Lymphogranuloma venereum
- Encephalitis of unknown etiology
  - Acute disseminated encephalomyelitis—following exanthems such as measles, vaccination against rabies and cowpox, and serum reactions
  - Acute hemorrhagic encephalitis
    - Acute brain purpura
    - Acute necrotizing hemorrhagic encephalopathy (hemorrhagic leukoencephalitis of Hurst)
  - Encephalitis complicating scarlet fever and rheumatic fever
  - Acute "toxic" encephalopathy

## PATHOLOGY OF ENCEPHALITIS

The neuropathological changes in this heterogeneous group of inflammatory diseases appear, at first glance, to be hopelessly complex. Not only are the diseases varied but also many of them have a predilection for special parts of the nervous sys-

\*From the Neurological Service, Boston City Hospital, the Haynes Memorial and Evans Memorial, Massachusetts Memorial Hospitals, the Department of Neurology, Harvard Medical School, and the Department of Medicine, Boston University School of Medicine.

‡Assistant professor of medicine, Boston University School of Medicine, physician and chief of service, Haynes Memorial, and assistant member, Evans Memorial, Massachusetts Memorial Hospitals.

§Japanese B, Russian tick borne, looping ill, and Australian X encephalitis are omitted from this classification and discussion because they have not been seen in the United States.

tem However, a survey of the morbid anatomy will show that there are only a limited number of ways in which the nervous system can react and that some pathological changes, common to all neurologic diseases of this type, depend more on special properties of brain tissue than on the causative agent For example, nerve cells can only react by degeneration and death, whatever the disease process, and regeneration does not occur The large amount of fatty material in the sheaths of the myelinated nerve fibers will, if caused to degenerate, excite the formation of phagocytes, both microglial and histiocytic, which form such a prominent feature of all inflammatory diseases Also, microglia will be activated by the selective degeneration of nerve cells and will assume elongated or pleomorphic forms often arranged in clusters or nodules, a process referred to as neuronophagia In some diseases, such as rabies and typhus fever, nodules of microglia, histiocytes and inflammatory cells sometimes known by special names — Babes's nodules in rabies — are present The neuroglial cells or astrocytes undergo hyperplasia in all subacute and chronic diseases and, since there is relatively little fibrous connective tissue in the brain, account for the reparative process — namely, gliosis Another general feature of all types of encephalitis is the infiltration of the perivascular spaces of Virchow-Robin, which have no counterpart in other organs, by lymphocytes, plasma cells or neutrophilic leukocytes, or all three This is especially prominent around the cortical and subependymal vessels The meninges are usually infiltrated with cells of the same type All these changes — that is, nerve-cell degeneration and neuronophagia, myelin destruction and its removal by macrophages, perivascular and meningeal infiltrates of inflammatory cells and ultimate gliosis — may occur in any inflammatory disease of the brain or spinal cord

Each of the different types of encephalitis is distinguished pathologically by the presence of the causative agent in the nervous tissue, the character of the lesion and the distribution of the lesions within the brain, spinal cord and peripheral nerves Demonstration of the causative agent by special stains or by culture is the only means by which a specific diagnosis can be made This is possible in most of the bacterial, fungous, spirochetal and parasitic diseases of the nervous system and in a few of the virus diseases by the occurrence of inclusion bodies In other infections, particularly those due to rickettsias and viruses, the etiologic factor has not been isolated or is so difficult to demonstrate that the diagnosis must depend either on the character and distribution of the lesions or on special serologic tests

The pathological changes in the bacterial, fungous, rickettsial, spirochetal and parasitic infections of the nervous system, with due allowance

for the special anatomic peculiarities of nervous tissue, closely resemble those in other viscera The changes in the brain in such diseases are viewed as part of a generalized infection and are not usually given separate consideration These general pathological findings are quite well known, having been well presented in most textbooks of pathology, and it is not necessary to describe them here

Neurotropic viruses, which comprise a large portion of the encephalitides due to viruses, exert their deleterious effects principally on the nervous system and have the following unique properties they enter the nervous system along nerves and spread by way of neurones from one part to another, they are incorporated into the protoplasm of the nerve cells and form, in some cases, intracytoplasmic or intranuclear inclusion bodies, and they have an affinity for certain groups of neurones

The nervous system reacts to many of the neurotropic virus infections in a fairly uniform manner There is evidence of nerve-cell destruction, proliferation of microglial cells, meningeal and perivascular infiltrates of lymphocytes and gliosis In some of the more strictly neurotropic virus infections, such as poliomyelitis and encephalitis lethargica, neurone damage or destruction is the primary event, and the activation of microglial cells and probably the meningeal, perivascular infiltration are secondary This type of reaction is so characteristic that the pathologist is probably justified in inferring from its presence the existence of a virus The occurrence of this type of pathological reaction is the chief basis for classifying encephalitis lethargica and herpes zoster as virus infections because in neither disease has the organism been isolated In other more acute forms of encephalitis, such as St Louis, equine and Japanese B, however, the brain damage is not limited to the nerve cells These forms have therefore been called pantropic instead of neurotropic In these there are scattered petechial hemorrhages, focal areas of tissue necrosis and microglial proliferation, and lymphocytic and neutrophilic leukocytic infiltrates in the gray matter and to a slight extent the white matter All the proved virus infections of the nervous system are essentially diseases of the gray matter — that is, polioclastic

Although many types of virus disease of the brain conform to the general type of pathological reaction described above, minor differences between them deserve special emphasis

In *encephalitis lethargica* (epidemic or Type A encephalitis), as in most infections of the brain, there are usually no gross changes or, at most, only slight opacity of the arachnoid membrane, congestion of vessels in the meninges, occasionally a few petechial hemorrhages in the gray matter and slight brain swelling There is marked destruction of the nerve cells in the substantia nigra, nuclei

in the hypothalamus, globus pallidus and tegmentum of the pons. Relatively few lesions are seen in the cerebral cortex and cerebellum, medulla and spinal cord. These lesions are of several types. Many nerve cells disappear completely, and others appear altered in several ways — that is, shrunken or chromatolytic. There are nodules of transitional microglial cells and astrocytes and parenchymatous infiltrations of lymphocytes and plasma cells. Lymphocytes and mononuclear leukocytes are also found in the perivascular spaces, chiefly about the veins, in the midbrain, walls of the third ventricle and basal ganglions. Meningeal infiltration is slight. Minute bodies have been demonstrated by toluidine blue and silver stains in the cytoplasm of nerve cells, but a definite opinion regarding their nature has not been expressed. Definite inclusion bodies have not been identified. In subacute cases, inflammatory cells are less numerous, and reparative gliosis more pronounced, in the chronic cases which are the only ones being seen by present-day pathologists, the chief findings are loss of and degeneration of neurones, especially in the substantia nigra, which may be grossly depigmented, and gliosis (von Economo<sup>3</sup>).

In *St. Louis encephalitis* the lesions are fairly uniformly distributed through the cerebral cortex, basal ganglions and brain stem. Occasionally petechial hemorrhages and congestion of blood vessels are noted. There is a mild leptomeningeal infiltration of lymphocytes and other mononuclear cells at the base of the brain, and the perivascular spaces contain similar cells. The nerve-cell injury varies with the severity of the infection, in severe cases swelling and chromatolysis, or shrinkage of cell bodies and finally disappearance of cells occurs. Focal and diffuse infiltrations of lymphocytes and, in acute cases, neutrophilic leukocytes are found. Neuronophagia is prominent. Foci of tissue necrosis, both interstitial and parenchymatous, with microglial proliferation and gliosis in the gray and to a slight extent the adjacent white matter, are not infrequent (Weil<sup>4</sup>). *St. Louis encephalitis* differs from *encephalitis lethargica* in that the lesions are more widely distributed through the cerebrum, the meningitis is more severe, nerve-cell damage in the pallidum and the substantia nigra is less marked, and focal necrosis and microglial proliferation are more extensive. The picture in Japanese B encephalitis is indistinguishable from that of *St. Louis encephalitis* (Zimmerman<sup>5</sup>). Foci of necrosis with demyelination and in more chronic cases, gliosis and even calcification with giant-cell formation have been reported. In neither disease are inclusion bodies seen.

In *equine encephalitis* the lesions are also scattered widely throughout the nervous system: the brain stem, basal ganglions and cerebral cortex are involved. In the acute cases there are focal and

diffuse lesions with destruction of nerve cells and interstitial tissue and extensive infiltration of neutrophilic leukocytes, lymphocytes and mononuclear leukocytes. The endothelium of the arterioles and capillaries is proliferated, necrosis of endothelial cells, fibrin impregnation and thrombi are occasionally seen in some such vessels. Myelin is destroyed in some of the foci (Farber et al.<sup>6</sup>). The meningeal reaction is more intense, the extent of brain damage including nerve-cell degeneration is greater, and migration of neutrophilic leukocytes is more prominent in the Eastern variety, than in other forms of encephalitis. Actually however, there are only minor differences between equine, *St. Louis* and Japanese B encephalitis. In neither Eastern nor Western forms have inclusion bodies been found.

In acute cases of *poliomyelitis* extreme congestion of blood vessels and swelling of the spinal cord may be observed grossly. The greatest damage is in the spinal cord, where, regardless of the distribution of paralytic symptoms, lesions can be found in every segment. The motor cortex, globus pallidus, substantia nigra, subthalamus, tegmentum of the midbrain, pons and medulla and the cerebellum are also involved frequently (Bodian<sup>7</sup>). The lesions are confined to gray matter for the most part and vary in intensity. Nerve cells become shrunken and darkly stained and disintegrate in an incredibly short time. Migration of neutrophilic leukocytes into the affected tissue occurs in the first day or two of the infection and is accompanied and followed by the appearance of transitional forms of microglia and activated histiocytes. Infiltration of the perivascular spaces and meninges by neutrophilic leukocytes, lymphocytes and other mononuclear cells occurs. Neuronophagia is pronounced. Secondary degeneration of motor-nerve fibers and of tracts in the anterior and lateral columns of the spinal cord become evident later. Gliosis is prominent in the older lesions. Pathologists are not in complete agreement about the occurrence of intranuclear inclusion bodies. *Poliomyelitis* is distinguished from other forms of encephalitis by the more severe affection of the spinal cord and the relative paucity of focal-tissue necrosis.

In *herpes zoster* the lesions are usually confined to one or several contiguous dorsal-root ganglions and their corresponding peripheral nerves and spinal roots (Denny-Brown, Adams and Fitzgerald<sup>8</sup>). In severe cases, part or all of the sensory ganglion may undergo complete necrosis with or without hemorrhage, whereas in milder cases some of the nerve cells survive and necrosis of the interstitial tissue is less severe or does not occur at all. There is degeneration of the fibers of the damaged nerve cells in both the peripheral nerve and dorsal root. The adjacent ventral or motor root may also be affected. The involved ganglions, nerves and roots are infiltrated by lymphocytes, mononuclear cells and a variable number of plasma cells. Often,

similar cells are seen in the pia arachnoid, in the perivascular spaces and in the homolateral posterior and ventral horns of gray matter of related spinal segments. The latter findings, combined with nerve-cell destruction and microglial proliferation, have the aspect of a unilateral poliomyelitis. In addition, cells of the epidermis swell, coalesce, vacuolate and exhibit large intranuclear inclusion bodies (Lipschutz<sup>9</sup>). The latter are not found in the nervous system. In exceptional cases involvement of the brain and spinal cord is widespread, giving a picture of encephalitis or myelitis. Perivascular lymphocytic infiltrations and scattered small perivascular hemorrhages have been found by Biggart and Fisher<sup>10</sup> in the medulla, cerebellar nuclei, thalamus and hypothalamus. Nerve cells at various levels of the brain stem and cortex had undergone chromatolysis. In such cases it is sometimes difficult to exclude the possibility that the zoster infection is a complication of another type of encephalitis.

In the few autopsies that have been performed in cases of epidemic parotitis the principal lesions have comprised scattered leptomeningeal and perivascular infiltrations of lymphocytes and other mononuclear cells without definite parenchymatous changes (Larkin<sup>11</sup>). In isolated cases the typical foci of perivenous demyelination and microglial proliferation that are characteristic of post-infectious encephalomyelitis, or an associated thrombosis of venous sinuses, have been reported.

In the few reports of post-mortem examinations in benign lymphocytic choriomeningitis the only significant neuropathologic abnormalities consisted of a leptomeningitis with lymphocytes and other mononuclear cells in the pia arachnoid, subarachnoid and perivascular spaces. Around some of the veins in the cerebral white matter there were small numbers of lymphocytes. Inclusion bodies were seen in the cytoplasm of some of the nerve cells (Viets and Warren<sup>12</sup>).

In the few cases of encephalitis with Type A intranuclear inclusion bodies, there has been degeneration of the nerve cells in the cerebral cortex, especially the precentral and hippocampal convolutions, the basal ganglions, midbrain, pons, medulla and the anterior and posterior horns of the spinal cord. Numerous small foci of necrosis also occur in the gray and white matter. Proliferation of microglial cells and perivascular and slight leptomeningeal infiltrations of lymphocytes were most pronounced in places where the neuronal degeneration was severe (Brain, Greenfield, and Russell<sup>13</sup>).

The central-nervous-system involvement in infectious mononucleosis takes the form of a leptomeningitis with the infiltrating cells consisting of lymphocytes, plasma cells and other mononuclear elements of lymphocytic or histiocytic origin (so-called abnormal lymphocytes). In a few cases wide-

spread degeneration of the peripheral nerves and dorsal-root-ganglion cells and extensive infiltrations of these structures by inflammatory cells have occurred. Aside from swelling and chromatolysis of the spinal anterior-horn cells, scattered nodules of glial cells and lymphocytes are the only other important changes in the nervous system<sup>14-16</sup>.

In one of the very few fatal cases of *lymphogranuloma venereum*, post-mortem examination revealed a diffuse meningeal reaction with predominant lymphocyte and plasma-cell infiltration and localized areas of subpial necrosis.

In rabies, there are well marked inflammatory lesions in the sensory ganglions, spinal cord, mid-brain, cerebellar cortex, hippocampal convolutions, olfactory bulbs and, sometimes, other parts of the cerebral cortex. Infiltrations of neutrophilic leukocytes and lymphocytes, both diffuse and perivascular, proliferation of microglial cells and astrocytes, nodules of glial and inflammatory cells (Babes) and lymphocytic invasion of the meninges make up the pathologic picture. Nerve-cell destruction is prominent. Characteristic cytoplasmic inclusion bodies (Negri bodies) are found in intact relatively normal nerve cells, particularly those in the hippocampal gyrus and cerebellar cortex. The distribution of the lesions is determined, to some extent, by the location of the wound. In bites of the leg the gray matter of the lumbar sensory ganglions is involved. In some cases of so-called "dumb rabies" the changes are largely confined to the spinal cord and resemble poliomyelitis (Hurst and Pawan<sup>17</sup>).

The pathology of the encephalitudes of unknown cause is essentially one of myelin destruction, microglial proliferation and meningeal and perivascular lymphocytic and mononuclear infiltrations. Unlike the known neurotropic virus infections the greatest damage is to white matter, and the nerve cells are affected slightly or not at all—hence the common designation myelinoclastic or leukoclastic encephalitis for this group. The microglial reaction, which develops early in the course of the disease, is probably secondary to damage of myelinated nerve fibers<sup>18, 19</sup>. Thrombosis of veins, although hypothesized as the cause of the demyelination, has not been found in our material.

There are no important pathological differences between the acute disseminated encephalomyelitis that follows measles, chicken pox, smallpox, injection with cowpox or rabies vaccine, and possibly allergic reactions to heterologous protein such as horse serum. All are alike so far as the myelin is destroyed in minute perivascular or subpial foci, the axis cylinders are damaged to a much less degree and necrosis of interstitial tissue does not occur. Although this condition follows certain acute exanthems believed to be caused by a virus, no causative agent has been isolated from the nervous system.

It has been suggested that acute disseminated encephalomyelitis and acute multiple sclerosis or even Schilder's disease are related. At present, however, the differences between these diseases are far more impressive than the similarities, and there is no substantial evidence that either multiple sclerosis or Schilder's disease is inflammatory.

*Acute hemorrhagic encephalitis*, acute necrotizing hemorrhagic encephalopathy and hemorrhagic leukoencephalitis are names that refer to a pathologic process consisting of hemorrhage and necrosis of the brain tissue. Although cases of this type are more frequent during epidemics of encephalitis, they occur sporadically at other times. From a review of our material and other published cases,<sup>20</sup> we have concluded that at least two different disease entities had been described under this heading. In one type there is one large area or several smaller confluent areas confined either to the cerebral white matter or to the brain stem, with extensive necrosis of all tissue elements including many of the small blood vessels, exudation of fibrin and migration of neutrophilic leukocytes in the damaged brain and adjacent leptomeninges. This usually takes a rapidly fatal course, although subacute and chronic cases with corresponding differences in pathology are known. They have all the aspects of an allergic inflammation. The other type is essentially a brain purpura with petechial hemorrhages and small nonhemorrhagic perivascular foci of tissue damage that are widely disseminated through the white matter. A proliferation of microglial cells and histiocytes in these foci can usually be demonstrated, but inflammatory reaction is entirely absent. The degree of damage to myelinated nerve fibers and the ease with which it can be demonstrated depend somewhat on the duration of the disease. This type of brain purpura is more suggestive of a toxic damage to blood vessels than an encephalitis in the strict sense of the word. Viruses or bacteria have not been identified in either of these two types of lesion.

The other forms of encephalitis of indeterminate etiology lack precise pathological definition. In fatal cases of scarlet fever a variety of different pathological changes, such as brain hemorrhage, embolism and hemorrhagic necrosis, have been described. However, very few such cases have been examined by present-day pathological techniques. From the most authoritative writings on rheumatic fever it seems reasonably well established that Aschoff bodies do not occur in the nervous system. Furthermore, most of the reported cases of so-called rheumatic arteritis do not stand careful scrutiny. Even for Sydenham's chorea, an accepted neurologic complication of rheumatic fever, there is no assignable morbid anatomy. Additional pathological studies of cases of rheumatic fever and scarlet fever with aseptic meningitis and neurologic symptoms are needed.

There is the same uncertainty concerning the pathologic changes in the exceptional cases in which an injection of tetanus toxoid or T A B vaccine has been followed by a meningoencephalitis or myelitis (Palmer<sup>21</sup>). Autopsy has disclosed findings identical with or very closely resembling those of poliomyelitis in some cases and postvaccinal encephalomyelitis in others.

Acute "toxic" encephalopathy is another condition about which there is much difference of opinion. The brain edema, the acute changes in the cortical neurones, the congestion of meningeal vessels and the slight hyperplasia of the adventitial and endothelial cells of small vessels sometimes called "productive encephalitis" are held by some writers to be responsible for the neurologic symptoms. Others maintain that they are artifacts or nonspecific reactions to fever, shock, anoxia and so forth. It is clear that there is no sign of inflammation and that in such transient and reversible neurologic syndromes as this one the expected pathophysiology will be subtle and difficult to demonstrate by present-day methods.

#### CLINICAL ASPECTS

Each of the types of encephalitis due to visible microbes can usually be recognized by the symptoms and laboratory findings of that particular disease. There should, for example, be no difficulty in distinguishing diseases as different as general paresis, trichinosis and subacute bacterial endocarditis. In these, as well as in neurotropic virus infections, involvement of the nervous system is indicated by the occurrence of general symptoms such as drowsiness, confusion, stupor or coma and of focal symptoms such as convulsions, hemiplegia, aphasia, ataxia, cranial-nerve palsies, tremor, chorea, athetosis and rigidity and by evidence of meningeal irritation—that is, headache and stiff neck. The cerebrospinal fluid usually contains an excess of cells, mostly lymphocytes, and increased amounts of protein with normal sugar and chloride levels.

The clinical syndromes produced by virus diseases of the brain, which have been reviewed recently by Rivers,<sup>22</sup> depend not on any peculiarity of the virus itself but on the location of the major pathologic changes. For instance poliomyelitis differs from St. Louis encephalitis because of the presence of predominant spinal motor symptoms and a paucity of cerebral symptoms. In the differential diagnosis of virus diseases of the brain, reliance must be placed not only on the clinical picture but also on such epidemiologic features as the geographic location and season of the year, as well as on the coexistence of systemic symptoms and the presence of cerebrospinal-fluid abnormalities. Sometimes even pathological examination will not suffice, and the diagnosis can be established only by special laboratory procedures such as isolation of the virus after embronated egg inoculation.

similar cells are seen in the pia arachnoid, in the perivascular spaces and in the homolateral posterior and ventral horns of gray matter of related spinal segments. The latter findings, combined with nerve-cell destruction and microglial proliferation, have the aspect of a unilateral poliomyelitis. In addition, cells of the epidermis swell, coalesce, vacuolate and exhibit large intranuclear inclusion bodies (Lipschutz<sup>9</sup>). The latter are not found in the nervous system. In exceptional cases involvement of the brain and spinal cord is widespread, giving a picture of encephalitis or myelitis. Perivascular lymphocytic infiltrations and scattered small perivascular hemorrhages have been found by Biggart and Fisher<sup>10</sup> in the medulla, cerebellar nuclei, thalamus and hypothalamus. Nerve cells at various levels of the brain stem and cortex had undergone chromatolysis. In such cases it is sometimes difficult to exclude the possibility that the zoster infection is a complication of another type of encephalitis.

In the few autopsies that have been performed in cases of *epidemic parotitis* the principal lesions have comprised scattered leptomeningeal and perivascular infiltrations of lymphocytes and other mononuclear cells without definite parenchymatous changes (Larkin<sup>11</sup>). In isolated cases the typical foci of perivenous demyelination and microglial proliferation that are characteristic of post-infectious encephalomyelitis, or an associated thrombosis of venous sinuses, have been reported.

In the few reports of post-mortem examinations in benign *lymphocytic choriomeningitis* the only significant neuropathologic abnormalities consisted of a leptomeningitis with lymphocytes and other mononuclear cells in the pia arachnoid, subarachnoid and perivascular spaces. Around some of the veins in the cerebral white matter there were small numbers of lymphocytes. Inclusion bodies were seen in the cytoplasm of some of the nerve cells (Viets and Warren<sup>12</sup>).

In the few cases of encephalitis with Type A intranuclear inclusion bodies, there has been degeneration of the nerve cells in the cerebral cortex, especially the precentral and hippocampal convolutions, the basal ganglions, midbrain, pons, medulla and the anterior and posterior horns of the spinal cord. Numerous small foci of necrosis also occur in the gray and white matter. Proliferation of microglial cells and perivascular and slight leptomeningeal infiltrations of lymphocytes were most pronounced in places where the neuronal degeneration was severe (Brain, Greenfield, and Russell<sup>13</sup>).

The central-nervous-system involvement in *infectious mononucleosis* takes the form of a leptomeningitis with the infiltrating cells consisting of lymphocytes, plasma cells and other mononuclear elements of lymphocytic or histiocytic origin (so-called abnormal lymphocytes). In a few cases wide-

spread degeneration of the peripheral nerves and dorsal-root-ganglion cells and extensive infiltrations of these structures by inflammatory cells have occurred. Aside from swelling and chromatolysis of the spinal anterior-horn cells, scattered nodules of glial cells and lymphocytes are the only other important changes in the nervous system<sup>14-16</sup>.

In one of the very few fatal cases of *lymphogranuloma venereum*, post-mortem examination revealed a diffuse meningeal reaction with predominant lymphocyte and plasma-cell infiltration and localized areas of subpial necrosis.

In rabies, there are well marked inflammatory lesions in the sensory ganglions, spinal cord, midbrain, cerebellar cortex, hippocampal convolutions, olfactory bulbs and, sometimes, other parts of the cerebral cortex. Infiltrations of neutrophilic leukocytes and lymphocytes, both diffuse and perivascular, proliferation of microglial cells and astrocytes, nodules of glial and inflammatory cells (Babes) and lymphocytic invasion of the meninges make up the pathologic picture. Nerve-cell destruction is prominent. Characteristic cytoplasmic inclusion bodies (Negri bodies) are found in intact relatively normal nerve cells, particularly those in the hippocampal gyrus and cerebellar cortex. The distribution of the lesions is determined, to some extent, by the location of the wound. In bites of the leg the gray matter of the lumbar sensory ganglions is involved. In some cases of so-called "dumb rabies" the changes are largely confined to the spinal cord and resemble poliomyelitis (Hurst and Pawan<sup>17</sup>).

The pathology of the encephalitides of unknown cause is essentially one of myelin destruction, microglial proliferation and meningeal and perivascular lymphocytic and mononuclear infiltrations. Unlike the known neurotropic virus infections the greatest damage is to white matter, and the nerve cells are affected slightly or not at all — hence the common designation myelinoclastic or leukoclastic encephalitis for this group. The microglial reaction, which develops early in the course of the disease, is probably secondary to damage of myelinated nerve fibers<sup>18, 19</sup>. Thrombosis of veins, although hypothesized as the cause of the demyelination, has not been found in our material.

There are no important pathological differences between the acute disseminated encephalomyelitis that follows measles, chicken pox, smallpox, injection with cowpox or rabies vaccine, and possibly allergic reactions to heterologous protein such as horse serum. All are alike so far as the myelin is destroyed in minute perivascular or subpial foci, the axis cylinders are damaged to a much less degree and necrosis of interstitial tissue does not occur. Although this condition follows certain acute exanthems believed to be caused by a virus, no causative agent has been isolated from the nervous system.

It has been suggested that acute disseminated encephalomyelitis and acute multiple sclerosis or even Schilder's disease are related. At present, however, the differences between these diseases are far more impressive than the similarities, and there is no substantial evidence that either multiple sclerosis or Schilder's disease is inflammatory.

*Acute hemorrhagic encephalitis* acute necrotizing hemorrhagic encephalopathy and hemorrhagic leukoencephalitis are names that refer to a pathologic process consisting of hemorrhage and necrosis of the brain tissue. Although cases of this type are more frequent during epidemics of encephalitis they occur sporadically at other times. From a review of our material and other published cases,<sup>20</sup> we have concluded that at least two different disease entities had been described under this heading. In one type there is one large area or several smaller confluent areas confined either to the cerebral white matter or to the brain stem, with extensive necrosis of all tissue elements including many of the small blood vessels, exudation of fibrin and migration of neutrophilic leukocytes in the damaged brain and adjacent leptomeninges. This usually takes a rapidly fatal course, although subacute and chronic cases with corresponding differences in pathology are known. They have all the aspects of an allergic inflammation. The other type is essentially a brain purpura with petechial hemorrhages and small nonhemorrhagic perivascular foci of tissue damage that are widely disseminated through the white matter. A proliferation of microglial cells and histiocytes in these foci can usually be demonstrated, but inflammatory reaction is entirely absent. The degree of damage to myelinated nerve fibers and the ease with which it can be demonstrated depend somewhat on the duration of the disease. This type of brain purpura is more suggestive of a toxic damage to blood vessels than an encephalitis in the strict sense of the word. Viruses or bacteria have not been identified in either of these two types of lesion.

The other forms of encephalitis of indeterminate etiology lack precise pathological definition. In fatal cases of scarlet fever a variety of different pathological changes, such as brain hemorrhage, embolism and hemorrhagic necrosis, have been described. However, very few such cases have been examined by present-day pathological techniques. From the most authoritative writings on rheumatic fever it seems reasonably well established that Aschoff bodies do not occur in the nervous system. Furthermore, most of the reported cases of so-called rheumatic arteritis do not stand careful scrutiny. Even for Sydenham's chorea, an accepted neurologic complication of rheumatic fever, there is no assignable morbid anatomy. Additional pathological studies of cases of rheumatic fever and scarlet fever with aseptic meningitis and neurologic symptoms are needed.

There is the same uncertainty concerning the pathologic changes in the exceptional cases in which an injection of tetanus toxoid or T A B vaccine has been followed by a meningoencephalitis or myelitis (Palmer<sup>21</sup>). Autopsy has disclosed findings identical with or very closely resembling those of poliomyelitis in some cases and postvaccinal encephalomyelitis in others.

Acute "toxic" encephalopathy is another condition about which there is much difference of opinion. The brain edema, the acute changes in the cortical neurones, the congestion of meningeal vessels and the slight hyperplasia of the adventitial and endothelial cells of small vessels sometimes called "productive encephalitis" are held by some writers to be responsible for the neurologic symptoms. Others maintain that they are artifacts or nonspecific reactions to fever, shock, anoxia and so forth. It is clear that there is no sign of inflammation and that in such transient and reversible neurologic syndromes as this one the expected pathophysiology will be subtle and difficult to demonstrate by present-day methods.

#### CLINICAL ASPECTS

Each of the types of encephalitis due to visible microbes can usually be recognized by the symptoms and laboratory findings of that particular disease. There should, for example, be no difficulty in distinguishing diseases as different as general paresis, trichinosis and subacute bacterial endocarditis. In these, as well as in neurotropic virus infections, involvement of the nervous system is indicated by the occurrence of general symptoms such as drowsiness, confusion, stupor or coma and of focal symptoms such as convulsions, hemiplegia, aphasia, ataxia, cranial-nerve palsies, tremor, chorea, athetosis and rigidity and by evidence of meningeal irritation—that is, headache and stiff neck. The cerebrospinal fluid usually contains an excess of cells, mostly lymphocytes, and increased amounts of protein with normal sugar and chloride levels.

The clinical syndromes produced by virus diseases of the brain, which have been reviewed recently by Rivers,<sup>22</sup> depend not on any peculiarity of the virus itself but on the location of the major pathologic changes. For instance, poliomyelitis differs from St. Louis encephalitis because of the presence of predominant spinal motor symptoms and a paucity of cerebral symptoms. In the differential diagnosis of virus diseases of the brain, reliance must be placed not only on the clinical picture but also on such epidemiologic features as the geographic location and season of the year, as well as on the coexistence of systemic symptoms and the presence of cerebrospinal-fluid abnormalities. Sometimes even pathological examination will not suffice and the diagnosis can be established only by special laboratory procedures such as isolation of the virus after embronated egg inoculation.

the determination of the presence of neutralizing antibody or the demonstration of increasingly positive serologic reactions such as complement fixation and inhibition of erythrocyte agglutination.

In the New England states, during the past decade, there have been no verified cases of acute encephalitis lethargica, St. Louis encephalitis has not been reported in this area, and Eastern equine encephalitis has not occurred except possibly in isolated cases since 1938-1939. Japanese B, Australian X, Russian tick-borne and Western or Venezuelan encephalitis are unknown here. Mumps meningo-encephalitis, infectious mononucleosis, poliomyelitis, herpes zoster, herpes simplex, rabies, lymphocytic choriomeningitis and lymphogranuloma venereum are the diseases that have been and will undoubtedly continue to be encountered in this section of the country.

Acute disseminated encephalomyelitis can usually be recognized without difficulty if there is knowledge of preceding measles, chicken pox, smallpox or other exanthem or of vaccination with either highly active viruses or attenuated ones. These diseases occur sporadically throughout the year, being more frequent whenever the exanthems are prevalent. It should be stressed that acute disseminated encephalomyelitis occasionally occurs before the rash becomes apparent, as in measles, and that in infants and children the encephalomyelitis may be so mild as to go undetected at the time of the acute exanthem only to become manifest years later when marked abnormalities in behavioral patterns appear.

Diseases suspected of being caused by filterable viruses, such as infectious mononucleosis, acute infectious hepatitis and acute infective polyneuritis, are apparently endemic in this region. We have seen a few cases with central-nervous-system involvement each year.

A brief summary of the clinical and laboratory findings of each of the types of encephalitis likely to be seen in the United States is presented below.

### *Encephalitis Lethargica*

Although acute cases are not being seen in the United States, a considerable number of patients who exhibit the sequelae of this disease continue to visit the outpatient clinics of medical and neurologic services. The most common manifestations are tremor, rigidity and slowness of voluntary movements, which combine to form a clinical picture resembling in some ways the hepatolenticular degeneration of Wilson and, in others, paralysis agitans. Important differences that should be stressed are the absence of corneal pigmentation (Kaiser-Fleischer rings), of the mixed static and intentional tremor, and of the evidence of liver disease, which are common in Wilson's disease and the presence of bizarre postures and gaits, and other muscular spasms such as oculogyric crises, and

torticollis, of coarse tremors and behavioral peculiarities, which are rarely encountered in paralysis agitans. The disease follows a variable course, usually slowly progressive, and death results years later from a severe muscular rigidity, which immobilizes the patient and finally from intercurrent infection. The majority of these patients are afebrile, and the cerebrospinal fluid is normal. In other words, there is no indication of an infectious process during the chronic phases of the illness, and often no trace of an inflammatory reaction at autopsy. A unique feature of the disease is this progressive damage of the basal ganglia over a long period, often without manifest inflammatory activity at autopsy. The diagnosis is made entirely from the clinical features of the disease. There are no confirmative laboratory tests.

### *St. Louis Encephalitis*

This disease differs from the von Economo type of encephalitis in its greater incidence in patients over the age of forty-five and in its prevalence during the summer months. The clinical picture shows tremendous variability because of the differences in severity of the infection and localization of the lesions in the brain and spinal cord. Three different syndromes have been described. The first consists of signs of meningeal irritation and increased intracranial pressure with difficulty in speech, ataxia, mental confusion and tremors of the tongue, lips or hands appearing abruptly without prodromal manifestations. Lethargy is not present in every patient. Paralysis is uncommon and is usually spastic in character. Eye-muscle involvement is extremely rare. The deep reflexes are usually exaggerated, and the abdominal ones are absent. Fever, usually disappearing within seven to ten days, may persist, in some cases, for from four to six weeks. The second is a syndrome characterized by prodromal manifestations of headache, generalized muscular pain, sore throat, mild conjunctivitis and photophobia that may last for from one to four days. After this period, the course of the disease is essentially the same as that in the first type. The third syndrome consists of so-called "abortive" cases of St. Louis encephalitis in which only fever and headache are present. These cases are usually detected because they occur in an area where this type of encephalitis is present, and lumbar puncture reveals spinal-fluid abnormalities.

The cerebrospinal fluid may be under normal or increased pressure, the protein is elevated, and the sugar normal, and there is an increase in the number of cells, which are chiefly lymphocytes, although other mononuclear elements may be present. No bacteria are demonstrable. Neutralization and the complement-fixation test aid in establishing the diagnosis.

The mortality in St. Louis encephalitis averages about 20 per cent, although it is much higher in the older and lower in the younger age group. When recovery occurs, there are usually no progressive sequelae as in lethargic encephalitis.

### *Equine Encephalitis*

A Massachusetts epidemic of *equine encephalitis* in the autumn of 1938 coincided with an epidemic of this disease in horses in the southwestern part of the state. The disease may have been transmitted by mosquitoes, which were prevalent at that time. Children were affected more often than adults. The onset was usually quite abrupt, and the course rapidly progressive, death occurring within a few hours to a few days. The dominant symptoms were fever, headache, nausea and vomiting, rapidly developing stupor or coma, convulsions, hemiplegia and ocular paralyses. The cell count in the cerebrospinal fluid averaged up to 1500 per cubic millimeter, often with a preponderance of neutrophilic leukocytes. The pressure was raised, the protein values were elevated, and the sugar was normal. The mortality was high, and a few of the surviving patients have had permanent neurologic residua, such as mental enfeeblement and hemiplegia. The virus can be isolated from brain tissue in fatal cases by the intracerebral inoculation of mice. There are also specific neutralization and complement-fixation tests that can be carried out with serum of patients drawn during the acute and convalescent phases.

### *Acute Anterior Poliomyelitis*

This disease is usually prominent in the summer and early autumn, although sporadic cases occur throughout the entire year. Prodromal symptoms such as headache, vomiting, diarrhea and upper respiratory manifestations, particularly sore throat, may be present for a few days. The invasion of the nervous system is marked by pain in the back and in the extremities, headache, stiff neck, rigidity of the spine and tenderness of nerves and muscles. A flaccid paralysis with loss of tendon reflexes but preservation of sensation develops a day or two later. Abortive types, nonparalytic meningeal forms and bulbar types have been described. Drowsiness and apathy are sometimes observed, but convulsions, coma and other cerebral symptoms of encephalitis are rare. Usually, the paralysis is asymmetrical, most often involving one leg or one arm, part of the trunk or both legs. Death is usually the result of involvement of the cardiac regulating or respiratory centers in the medulla, or both. In the first few days the cerebrospinal fluid usually contains 10 to 200 cells per cubic millimeter, both neutrophilic leukocytes and lymphocytes. The protein is often normal in the acute stages of the disease and gradually rises in succeeding weeks. As in all virus infections, the sugar and chloride are normal. Most workers believe that the virus is

disseminated by human contact. The pathway of entrance is debated, there is considerable evidence that the virus passes through the wall of the gastrointestinal tract and reaches the spinal cord along sympathetic nerves. Another possibility is that it extends from the pharynx to the medulla and cervical part of the spinal cord. There is no quick laboratory test for confirmation of the diagnosis. Demonstration of the virus in the feces or the nasopharyngeal secretions is difficult, protracted and, at the moment, clinically impractical. Neutralization tests are unreliable because of antigenic differences between strains of virus, there is no serologic test of value. The diagnosis can be established at autopsy by the character and distribution of the lesions or, sometimes, by careful study of the clinical course of the disease.

### *Herpes Zoster*

Herpes zoster is a specific infectious disease, probably caused by a virus, which has not yet been isolated. The disease begins with malaise, slight fever and pain along one or several nerve roots and is followed within three or four days by the characteristic vesicular eruption and local lymphadenopathy. Segmental sensory or motor paralysis, or both, may occur. When cranial ganglions are involved, several distinctive syndromes may occur: ophthalmoplegic zoster, affecting the Gasserian ganglion, geniculate zoster (Ramsay Hunt syndrome), affecting the geniculate or and probably more frequently the glossopharyngeal ganglions, and glossopharyngeal and vagus zoster, affecting the petrosal and jugular ganglions. In some cases the cerebrospinal fluid contains 5 to 200 cells per cubic millimeter, mostly lymphocytes, and an elevated total protein. Severe neuralgia and occasionally sensory loss or paralysis of a group of muscles are lasting complications. Cases of encephalitis as evidenced by increasing drowsiness, confusion and sphincter incontinence, myelitis with paraplegia and polyneuritis have been reported. The virus has never been isolated even from pathological material, and there are no reliable laboratory tests to prove its identity.

### *Mumps Meningoencephalitis*

Symptoms of meningitis may develop before, during or after mumps. Swelling of the salivary glands may be slight and escape notice or may be entirely absent during the entire course of the disease. The infection may involve organs other than the salivary glands such as the testes, lacrimal glands, breasts and pancreas. Usually, the patients are not very sick. The onset of symptoms is marked by headache, occasionally by drowsiness and confusion, and in rare cases by convulsions and coma and cranial-nerve palsies, particularly the seventh and eighth nerves. Signs of meningeal irritation are prominent.

the determination of the presence of neutralizing antibody or the demonstration of increasingly positive serologic reactions such as complement fixation and inhibition of erythrocyte agglutination.

In the New England states, during the past decade, there have been no verified cases of acute encephalitis lethargica, St. Louis encephalitis has not been reported in this area, and Eastern equine encephalitis has not occurred except possibly in isolated cases since 1938-1939. Japanese B, Australian X, Russian tick-borne and Western or Venezuelan encephalitis are unknown here. Mumps meningo-encephalitis, infectious mononucleosis, poliomyelitis, herpes zoster, herpes simplex, rabies, lymphocytic choriomeningitis and lymphogranuloma venereum are the diseases that have been and will undoubtedly continue to be encountered in this section of the country.

Acute disseminated encephalomyelitis can usually be recognized without difficulty if there is knowledge of preceding measles, chicken pox, smallpox or other exanthem or of vaccination with either highly active viruses or attenuated ones. These diseases occur sporadically throughout the year, being more frequent whenever the exanthems are prevalent. It should be stressed that acute disseminated encephalomyelitis occasionally occurs before the rash becomes apparent, as in measles, and that in infants and children the encephalomyelitis may be so mild as to go undetected at the time of the acute exanthem only to become manifest years later when marked abnormalities in behavioral patterns appear.

Diseases suspected of being caused by filterable viruses, such as infectious mononucleosis, acute infectious hepatitis and acute infective polyneuritis, are apparently endemic in this region. We have seen a few cases with central-nervous-system involvement each year.

A brief summary of the clinical and laboratory findings of each of the types of encephalitis likely to be seen in the United States is presented below.

### *Encephalitis Lethargica*

Although acute cases are not being seen in the United States, a considerable number of patients who exhibit the sequelae of this disease continue to visit the outpatient clinics of medical and neurologic services. The most common manifestations are tremor, rigidity and slowness of voluntary movements, which combine to form a clinical picture resembling in some ways the hepatolenticular degeneration of Wilson and, in others, paralysis agitans. Important differences that should be stressed are the absence of corneal pigmentation (Kaiser-Fleischer rings), of the mixed static and intentional tremor, and of the evidence of liver disease, which are common in Wilson's disease, and the presence of bizarre postures and gaits, and other muscular spasms such as oculogyric crises, and

torticollis, of coarse tremors and behavioral peculiarities, which are rarely encountered in paralysis agitans. The disease follows a variable course, usually slowly progressive, and death results years later from a severe muscular rigidity, which immobilizes the patient and finally from intercurrent infection. The majority of these patients are afebrile, and the cerebrospinal fluid is normal. In other words, there is no indication of an infectious process during the chronic phases of the illness, and often no trace of an inflammatory reaction at autopsy. A unique feature of the disease is this progressive damage of the basal ganglia over a long period, often without manifest inflammatory activity at autopsy. The diagnosis is made entirely from the clinical features of the disease. There are no confirmative laboratory tests.

### *St. Louis Encephalitis*

This disease differs from the von Economo type of encephalitis in its greater incidence in patients over the age of forty-five and in its prevalence during the summer months. The clinical picture shows tremendous variability because of the differences in severity of the infection and localization of the lesions in the brain and spinal cord. Three different syndromes have been described. The first consists of signs of meningeal irritation and increased intracranial pressure with difficulty in speech, ataxia, mental confusion and tremors of the tongue, lips or hands appearing abruptly without prodromal manifestations. Lethargy is not present in every patient. Paralysis are uncommon and are usually spastic in character. Eye-muscle involvement is extremely rare. The deep reflexes are usually exaggerated, and the abdominal ones are absent. Fever, usually disappearing within seven to ten days, may persist, in some cases, for from four to six weeks. The second is a syndrome characterized by prodromal manifestations of headache, generalized muscular pain, sore throat, mild conjunctivitis and photophobia that may last for from one to four days. After this period, the course of the disease is essentially the same as that in the first type. The third syndrome consists of so-called "abortive" cases of St. Louis encephalitis in which only fever and headache are present. These cases are usually detected because they occur in an area where this type of encephalitis is present, and lumbar puncture reveals spinal-fluid abnormalities.

The cerebrospinal fluid may be under normal or increased pressure, the protein is elevated, and the sugar normal, and there is an increase in the number of cells, which are chiefly lymphocytes, although other mononuclear elements may be present. No bacteria are demonstrable. Neutralization and the complement-fixation test aid in establishing the diagnosis.

tains several hundred to a thousand or more cells, of which the majority are lymphocytes. The sugar level is usually normal though a few values below 40 mg per 100 cc were found twice in 19 lumbar punctures in 1 case<sup>28</sup>. The protein is elevated and the colloidal-gold readings are abnormal. Characteristic genital or rectal lesions should suggest the possibility of lymphogranuloma venereum and a positive Frei test is confirmatory; this reaction may, however, be negative. The virus can be isolated from the cerebrospinal fluid by the intranasal or intracerebral inoculation of mice, and from the genital lesion or regional lymph nodes but not the blood stream. Complement fixation is an accepted diagnostic procedure. Although usually benign, this disease may occasionally run a rapidly fatal course<sup>29, 30</sup>.

### *Encephalitides of Unknown Origin*

Among the encephalitides of unknown origin, some, like those following rubeola and rubella, are related to known virus infections, but the causative agents have not been isolated from nervous tissue and the pathological picture does not resemble that of a virus disease. Although it has been postulated that the neurologic disturbance is due to the activation of a latent virus, concrete evidence to support this viewpoint has not been advanced. Recently, data suggesting an allergic reaction to nervous tissue during the course of the exanthem as the etiologic factor concerned in post-infectious encephalomyelitis have been presented<sup>31-34</sup>. The causative factors concerned in the other encephalitides — acute hemorrhagic, those complicating scarlet fever and rheumatic fever and the "toxic" type — are completely unknown.

### *Acute Disseminated Encephalomyelitis*

This accompanies measles more often than any other infection and occurs in from 1/400 to 1/1000 cases of this exanthematous disease. It has also been reported after rubella, varicella, variola and mumps. It occasionally appears without any recognizable exanthem. Usually, the neurologic symptoms occur four to six days after the onset of the skin eruption and are accompanied by a rise of temperature and pleocytosis of the cerebrospinal fluid. The neural manifestations may be those of diffuse cerebral involvement, — that is, confusion, convulsions and coma, — focal brain lesions (hemiplegia, hemianesthesia, aphasia, blindness or hemianopia), brain-stem involvement with cranial-nerve palsies or pseudobulbar palsy and cerebellar or spinal lesions such as ataxia and paraplegia. Although 10 to 20 per cent of patients die and there may be serious residua in as high as 65 per cent of the cases, a surprising degree of recovery often occurs. A similar clinical picture may develop a week to ten days after the beginning of antirabies vaccination, the administration of smallpox vaccine

or rarely the injection of horse serum in the prophylaxis of tetanus or treatment of diphtheria. The pathology has been described above. There are no laboratory tests of any value, but in fatal cases the diagnosis can be confirmed by the characteristic anatomic lesions, a history of contact with one of the infections listed above and the clinical course of the disease.

### *Acute Hemorrhagic Encephalitis*

We have studied the brain in 10 fatal cases, 3 of which were examined during life. The correct diagnosis was not made in any case, though it was mentioned in the differential diagnosis in 1. After an upper respiratory infection or during an influenza-like illness, fever, deep confusion, coma, convulsions and hemiplegia or quadriplegia appeared without assignable cause. The cerebrospinal fluid was normal in the cases of brain purpura and contained several hundred cells, mostly neutrophilic leukocytes, elevated protein, normal sugar and chloride in the cases of acute hemorrhagic necrotizing encephalopathy. The prominence of neurologic symptoms always raises the question of an encephalopathy due to a toxin, metastatic infection or a vascular lesion of the brain. No virus has been isolated from these cases. At present the diagnosis can only be confirmed by autopsy.

### *Encephalitis of Scarlet Fever and Rheumatic Fever*

In exceptional cases of recurrent rheumatic fever, scarlet fever and possibly other of the so-called rheumatic diseases, persistent fever and pleocytosis of the cerebrospinal fluid are accompanied by neurologic symptoms. A confusional psychosis sometimes with paranoid coloring, delirium, ataxia of limbs, reflex changes, stupor or coma has constituted the clinical picture in some cases, but other patients have had relatively few complaints or signs referable to the nervous system. In the cases of scarlet fever the signs of meningeal irritation and the pleocytosis of the cerebrospinal fluid, which usually consists of 100 to 200 lymphocytes per cubic millimeter, occur when the rash is desquamating<sup>35, 36</sup>. The symptoms do not respond to sulfonamide drugs or antistreptococcus serum, and penicillin has not been given sufficient trial. It is not yet certain whether the neurologic sequelae are due to a streptococcal septicemia and an interstitial encephalitis similar to that found by Mallory and Keefer<sup>37</sup> in other viscera or whether the brain lesions are the result of embolism secondary to endocarditis — that is, focal embolic encephalomyelitis<sup>38</sup>. The unsettled state of rheumatic encephalitis was mentioned above.

### *Acute "Toxic" Encephalopathy*

In many acute and severe infectious diseases such as pneumonia, influenza, diphtheria, pertussis, septicemia, scarlet fever, dysentery and typhoid fever, stiffness of the neck and spine, convulsions

### *Lymphocytic Choriomeningitis*

This is a benign meningitis that is often preceded by one or two weeks by systemic symptoms not unlike influenza. The onset of meningeal involvement is announced by headache and stiff neck and sometimes drowsiness, irritability and confusion. In a few cases, focal cerebral symptoms have occurred. The cerebrospinal fluid is under normal or increased pressure and contains 50 to 1500 cells per cubic millimeter, mostly lymphocytes. Sugar and chloride values are normal. Usually, recovery occurs in two or three weeks, and only a few fatal cases have been reported. The virus can be obtained from both the blood and cerebrospinal fluid. It has also been found in wild mice and rodents around human dwellings. The feces or the bite of the rodents is the source of human infections. This disease must be distinguished from tuberculous meningitis and mumps meningoencephalitis. Neutralization and complement-fixation tests are helpful in establishing the diagnosis (Farmer and Janeway<sup>23</sup>).

### *Infectious Mononucleosis*

Infectious mononucleosis or glandular fever is a pleomorphic disease that is occasionally accompanied by headaches, stiff neck, giddiness, nausea and vomiting. Its more specific nervous manifestations include delirium, lethargy, stupor and diplopia. The cerebrospinal fluid, which contains an excess of cells, up to several hundred lymphocytes and other mononuclear elements and an elevated total protein, attests to a meningitis and more specific nervous symptoms such as delirium, coma and diplopia to parenchymatous damage. In a few exceptional cases an ascending polyneuritis indistinguishable from the usual acute infectious or acute febrile polyneuritis has developed, being preceded or followed by jaundice. The diagnosis rests on the demonstration of abnormal lymphocytes in the circulating blood, enlargement of lymph nodes generally and often of the spleen and liver, and the presence in the serum of heterophil-antibody agglutinins for sheep erythrocytes. Since the causative agent has not been isolated, the viral etiology can only be predicated from the nature of the pathologic findings.

### *Herpes Simplex Encephalitis and Myelitis*

Several cases of encephalitis with large Type A intranuclear inclusion bodies in nerve and glial cells have been reported in the past two decades<sup>24-25</sup>. In at least 2 of these the virus of fever blisters or acute stomatopharyngitis has been isolated and shown by rising titers of neutralizing antibodies to have been the causative agent. It is reasonable to suppose that all the reported cases in which these intranuclear inclusion bodies were demonstrated are due to this virus.

Most of the cases have occurred in children. The onset is insidious. Alteration of character, impaired vision, ataxia, hemiparesis, disturbances of movement and posture in the form of rigidity, athetosis or dystonia, facial spasm, trismus and finally coma are listed as the distinctive features of the disease. The course is subacute, with progression to a fatal termination in one to four months. Except for a few lymphocytes in some cases the cerebrospinal fluid has been normal.

Because of the common symbiosis between this virus and man, the etiology of these cases is difficult to prove. Some antibody to this virus is present in a great number of healthy persons, and hence only with rising and falling titers with reference to a particular illness can this agent be implicated.

The fatal case of ascending myelitis in a laboratory technician after the bite of a supposedly healthy monkey that was reported by Sabin and Wright<sup>27</sup> has excited much controversy. He believed that this virus differed from that of herpes simplex, but other workers have since stated that it belongs to the same group.

### *Rabies*

This is an old and, from the historical point of view, important neurotropic virus infection that still exists in this country. The virus is present in many lower animals besides dogs, such as foxes, coyotes, wolves, skunks and vampire bats, and is transmitted to human beings through the bites of rabid animals. The incubation period is twenty to sixty days. The first symptoms are pain and numbness in or near the bite. Within a few days, restlessness, irritability and excitement alternating with drowsiness appear. Headache, stiff neck and rigidity of the spine are usually present. Violent convulsions, involuntary movements and characteristic spasm of the pharynx and larynx occur and have been interpreted by laymen as hydrophobia. Coma develops later. Death is inevitable once symptoms of rabies appear, but the use of anti-rabies vaccine early in the incubation period is of prophylactic value. A clinical picture of ascending myelitis, so-called "dumb" rabies or "Trinidad rabies" has been described<sup>17</sup>. There is no laboratory test to aid in the diagnosis during life. The finding of cytoplasmic inclusion bodies (Negri bodies) in the nerve cells of the Gasserian ganglions, the hippocampal gyrus or Purkinje cells of the rabid animal or infected man will establish the diagnosis. The virus is not found in the blood or spinal fluid of man.

### *Lymphogranuloma Venereum*

The viral origin of this disease is now accepted, and a few cases of so-called meningoencephalitis have been reported. The symptoms are fever, headache, stiff neck, mental confusion and an occasional cranial-nerve palsy. The cerebrospinal fluid con-

general methods used in the laboratory diagnosis of viral diseases. These tests are complex and expensive and are being done in only a few large medical centers. The laboratories that have been most generous in their help are those of the Rockefeller Institute, the National Institute of Health, the Children's Hospital in Philadelphia and the Diagnostic Laboratories of the Massachusetts Department of Public Health, which limits its efforts to the diagnosis of mumps and influenza virus infections. If material is submitted to these laboratories in suitable form, appropriate tests will be done, and the results reported promptly.

In all the established virus diseases the causative agent can be obtained from the spinal cord and brain. However, only in lymphocytic choriomeningitis is the virus found consistently in the blood and cerebrospinal fluid in sufficient concentration to make such tests worth while. In all the virus diseases of known etiology with the exception of rabies, poliomyelitis and herpes simplex, complement-fixation or neutralization tests are now available and are of diagnostic value. If positive these tests show only that the patient has at some previous date had this infection. To prove that a specific illness was caused by the virus in question two samples of blood serum, one taken as early in the disease as possible and the other late in convalescence (usually six weeks) should be submitted. If the first specimen contains no antibody or only a low titer and the second one shows a rise in antibody content the evidence is strong that the suspected disease was due to the virus in question.

Aseptic precautions should be taken in the collection of blood. The serum should be removed from clot as soon as possible, frozen and kept at very low temperatures if immediate examination cannot be done. Brain, preferably pieces from the hippocampal convolution, sensorimotor cortex and pons or spinal-cord tissue should be frozen in a mixture of alcohol and dry ice under sterile conditions or put in a 50 per cent solution of neutral glycerin. The diagnostic tests useful in establishing the viral origin in a case of encephalitis are presented in Table I.

### SUMMARY

Aside from the forms of encephalitis due to visible microbes such as bacteria, parasites, rickettsias and spirochetes the class of inflammatory brain diseases caused by filterable viruses has been seen rarely in New England during the past few years. In fact the only neurotropic viruses that we have encountered are mumps, poliomyelitis, lymphocytic choriomeningitis, herpes zoster and rabies. Acute disseminated or postinfectious encephalomyelitis, which is probably not of direct viral etiology, occurs sporadically after exanthematous disease and certain immunization procedures. In the last six years there have been 15 cases diagnosed

during life as virus encephalitis that underwent pathological examination at the Mallory Institute of Pathology. The final anatomic diagnoses were acute confusional psychosis (2 cases), metabolic disease with disturbed brain function (1 case), lead encephalopathy (1 case), focal embolic encephalomyelitis due to subacute bacterial endocarditis (4 cases), acute disseminated lupus erythematosus (1 case), tuberculous meningitis (3 cases), torulosis of the meninges (1 case), basilar-artery thrombosis (1 case) and brain abscess (1 case). From these pathological data one must conclude that a diagnosis of virus encephalitis in New England has at the present time a large probability of error. It is recommended that the word encephalitis not be used without a qualifying adjective. Thus, the neurologic syndrome in question should be analyzed to determine whether or not it is consistent with encephalitis lethargica, mumps, postinfectious encephalomyelitis and so forth. Admittedly, the neurologic symptoms of the different types of encephalitis are not by themselves distinctive but by habitually thinking in terms of specific disease entities and taking into account epidemiologic and laboratory data one can avoid serious diagnostic errors.

and stupor or coma may occur. This is especially true in children, when the neurologic disorder at times even obscures the signs of the primary pathologic process. The cervical rigidity is often so pronounced as to suggest the presence of meningitis, particularly when there is pneumonia of the right

be controlled death frequently occurs, or if the child survives, serious and permanent brain damage may follow. The syndrome is nonspecific, it varies little regardless of the associated disease. The diagnosis is made on purely clinical grounds. The condition must be distinguished from intracranial

TABLE 1 *Laboratory Diagnosis of Virus Diseases of the Nervous System*

DISEASE	PRESENCE OF VIRUS			METHOD OF DEMONSTRATING PRESENCE OF VIRUS	NEUTRALIZATION TEST	COMPLEMENT-FIXATION TEST	OTHER TESTS	PATHOLOGICAL FEATURES
	BLOOD	CEREBROSPINAL FLUID	BRAIN AND SPINAL CORD					
Rabies	0	0	+	Intracerebral inoculation in mice	0	?	—	Typical virus encephalomyelitis—that is, nerve-cell destruction, microglial proliferation, lymphocytic infiltration of meninges and perivascular spaces and Negri bodies
Poliomyelitis	0	0	+	Inoculation of spinal-cord suspensions, stool emulsions or throat washings after filtration intracerebrally, subcutaneously or intranasally into monkeys	+	0	—	Typical virus encephalomyelitis with predominance of lesions in spinal cord, brain stem and motor cortex
St. Louis encephalitis	0	0	+	Inoculation into mice intracerebrally or in embryonated egg	+	+	—	Typical virus encephalomyelitis; lesions in cerebral cortex, basal ganglia and brain stem; focal areas of necrosis
Western equine encephalitis	0	0	+	Intracerebral inoculation in mice	+	+	—	Same as those of St. Louis encephalitis
Eastern equine encephalitis	+	+	+	Intracerebral inoculation in mice	+	+	—	Same as those of St. Louis and Western encephalitis
Mumps meningo-encephalitis	+	+	+	Inoculation of embryonated egg	+	+	Fowl red-cell agglutinin inhibition	Meningitis—perivascular and meningeal infiltrations of lymphocytes and other mononuclear cells
Lymphogranuloma venereum	+	0	+	Inoculation of embryonated egg	+	+	Frei test	Same as those of mumps
Herpes simplex	?	?	+	Scarification of rabbit cornea; growth on embryonated egg; intracerebral inoculation in mice	+	Not reliable	—	Intranuclear inclusion bodies otherwise similar to St. Louis and equine encephalitis
Herpes zoster	0	0	0	None	0	0	—	Destruction of 2 or 3 sensory ganglia; lymphocytic infiltration of ganglia; nerve roots, meninges and unilateral segmental polymyelitis; vesicles in skin with intranuclear inclusions
Encephalitis lethargica	0	0	0	None	0	0	—	Typical virus encephalomyelitis; lesions chiefly in globus pallidus, midbrain and pons; less tissue necrosis than in St. Louis and equine encephalitis
Infectious mononucleosis	0	0	0	None	0	0	Heterophil antibody; sheep red-cell agglutinin	Infiltration of peripheral nerves, sensory ganglia, sensory roots and sometimes meninges with lymphocytes, plasma cells and histiocytes
Benign lymphocytic choromeningitis	+	+	+	Culture on embryonated egg; inoculation in mice, guinea pigs and monkeys	+	+	0	Meningitis—perivascular and meningeal infiltration with lymphocytes, macrophages and a few neutrophilic leukocytes

upper lobe. However, the cerebrospinal fluid is within normal limits. The course is variable. If the convulsions are suppressed and the infection promptly controlled, consciousness may be regained within a few hours and the rigidity may disappear, leaving no sequelae or only transient and reversible focal neurologic symptoms. If the infection cannot

suppurative processes and other types of encephalitis.

#### LABORATORY DIAGNOSIS OF ENCEPHALITIS

Correct diagnosis of neurotropic virus infections requires the aid of special laboratory tests. Cheever<sup>39</sup> has written an excellent review of the

committee of the Committee on Postgraduate Medical Education. The Secretary moved that the Council approve this recommendation. The motion was seconded, and it was so ordered by vote of the Council. (3) The Executive Committee unanimously approved the proposal to have the Society sponsor the art exhibit of the Massachusetts Physicians Art Association at the annual meetings. The Secretary moved that the Council approve this recommendation. The motion was seconded, and it was so ordered by vote of the Council. (4) The Executive Committee unanimously voted to approve of the establishment of a Section on Physiology and Pathology. The Secretary moved that the Council approve the establishment of such a section. The motion was seconded, and it was so ordered by vote of the Council. (5) The Executive Committee voted unanimously to approve the request of Dr. Augustus Thorndike to have the President appoint a committee to confer with the directors of the Bay State Medical Rehabilitation Clinic, a charitable, nonprofit clinic not connected with the state or federal governments.

The Secretary moved that the request be approved by the Council. The motion was seconded, and it was so ordered by vote of the Council.

The President then made the following appointments to that committee and asked for the approval of the Council. On a motion duly made and seconded it was so voted:

*To the Committee to meet with the Officers of the Bay State Medical Rehabilitation Center*

Dr. Charles H. Bradford, *Chairman*  
 Dr. W. Irving Clark  
 Dr. Walter Bauer  
 Dr. Joseph S. Barr  
 Dr. Hermann L. Blumgart  
 Dr. Otto J. Hermann  
 Dr. Arthur L. Watkins

(6) The Executive Committee voted unanimously not to approve the recommendations of the now extinct Committee on Medico-Legal Testimony to amend the By-laws in order to establish a standing committee on Medico-Legal Testimony. The Secretary moved that the Council approve this action of the Executive Committee. The motion was seconded, and it was so ordered by unanimous vote of the Council.

The Secretary then moved that the report of the Committee on Membership as distributed to the Executive Committee concerning transfers, retirements, deprivations and resignations be approved by the Council. The motion was seconded, and it was so ordered by vote of the Council.

The Secretary then stated that new business before the Executive Committee included the following:

(1) The resolution presented to it by the Hampden District Society was discussed and the committee

voted that the matter of the resolution be laid on the table until the next meeting of the Committee.

(2) The committee voted unanimously to approve the request to change the name of the Section on Physiotherapy to Section on Physical Medicine. The Secretary moved that the Council approve of this change in name. The motion was seconded, and it was so ordered by vote of the Council.

(3) The Secretary stated that the Executive Committee had given him permission to confer with the secretaries of the district societies in order to select candidates for the General Practitioners Award, the Executive Committee would select one candidate for presentation to the Council. The Secretary moved that the Council approve this action by the Executive Committee. The motion was seconded. Dr. Carl Bearse, Norfolk, moved that the motion be amended to the effect that unless a candidate receive a majority vote of the Executive Committee the decision be referred to the Council for action. (There was no second to this motion.) The President called for a vote on the original motion, and it was so ordered by a vote of the Council.

(4) The Secretary stated that the Executive Committee had approved the action of the President in acceding to the request of our counsel, Mr. Twomey, to submit a brief as a friend of the court. The President then explained that the matter concerned one of our fellows who had been sued by a patient because she claimed morphine addiction as a result of his treatment. The Court had found for the plaintiff, and the judge had upset the verdict. The case was to be tried in the Supreme Court.

On motion made by the Secretary and duly seconded, the Council voted to approve the action of the Executive Committee in this respect.

The President said that he would interrupt the usual procedure at this point to permit Dr. James C. McCann, Worcester, to report to the Council on the affairs of Blue Shield. Dr. McCann thanked the President and addressed the Council (Appendix No. 3).

Dr. Reardon thanked Dr. McCann for his report and called for the Committee Reports.

*Committee on Cancer* — Dr. Shields Warren, Suffolk, *Chairman*

Since no member of the Committee on Cancer was present, the Secretary moved acceptance of the report (Appendix No. 4). The motion was seconded, and it was so ordered by vote of the Council.

Dr. George Papen, Norfolk, stated that at a pre-Council meeting of the Norfolk District Medical Society it had been voted that the recommendations of the Committee on Cancer — "That the Massachusetts Medical Society endorse the principle of voluntary registration of cancer cases" — be tabled.

## MASSACHUSETTS MEDICAL SOCIETY

### PROCEEDINGS OF THE COUNCIL

Stated Meeting, October 6, 1948

A STATED meeting of the Council was called to order by the president, Dr Daniel B Reardon, Norfolk South, on Wednesday, October 6, 1948, at 10 30 a m in John Ware Hall, 8 Fenway, Boston

Two hundred and fifteen councilors (Appendix No 1) were present

The Secretary presented the record of the May 24, 1948, annual meeting of the Council as published in the *New England Journal of Medicine*, issue of July 22, 1948, and moved its acceptance The motion was seconded and it was so ordered by vote of the Council

#### APPOINTMENTS

The President then announced the following appointments all of which had been presented to the Executive Committee, with the exception of the Subcommittee on Medical Education

##### *To the Subcommittee of the Executive Committee on Blue Cross-Blue Shield Problems*

Dr Charles J E Kickham, *Chairman*  
 Dr Joseph C Merriam  
 Dr Harvey A. Kelly  
 Dr John Fallon  
 Dr Paul M Butterfield

##### *To the Temporary Committee on Council Rules and By-laws*

Dr Edward P Bagg, *Chairman*  
 Dr Elmer S Bagnall  
 Dr Frank R Ober  
 Dr Albert A Hornor

##### *To the Committee on Medical Economics*

Dr Henry A Robinson

##### *To the Committee on Society Headquarters*

Dr Dwight O'Hara

##### *To the Committee on Tax-Supported Medical Care*

Dr Francis P McCarthy

##### *To the Advisory Subcommittee on Medical Education*

Dr Arthur Jankelson, *Chairman*  
 Dr George E Gardner  
 Dr Raymond H Goodale  
 Dr Donald A Nickerson  
 Dr William A Hinton  
 Dr C Guy Lane  
 Dr Augustus Thorndike

The President asked for approval of these appointments, and it was so ordered by vote of the Council

The Secretary, on behalf of the Society presented the President with a gavel with his name and the years 1948-1949 engraved upon it The President accepted the gavel with thanks and said that he heartily approved of establishing the custom of presenting a gavel to each newly elected President

#### REPORTS OF COMMITTEES

*Executive Committee* — Dr H Quimby Gallupe, Middlesex South, *Secretary*

The Secretary presented the minutes of the meeting of the Executive Committee held on September 8, 1948, as mimeographed (Appendix No 2) and mailed to the Councilors and moved their acceptance The motion was seconded, and it was so ordered by vote of the Council

The Secretary then stated that under the matters referred to the Committee by the Council, (1) the question of whether or not the Society should receive certain gifts, the committee had voted to defer action until the Treasurer received further information from the American Medical Association and the Treasury Department (2) The Executive Committee unanimously approved of making the Committee on Postgraduate Assembly a sub-

The Secretary moved that the recommendation to conduct a state-wide health meeting and that the Council appropriate the sum of \$500 toward this important activity be approved. The motion was seconded, and it was so ordered by vote of the Council.

The President then stated that the Executive Committee did not approve of the recommendation to endorse an ascending scale of membership dues and the study of the question by a proper committee.

The Secretary moved that the Council, also not approve of this recommendation. The motion was seconded.

Dr Eliot Hubbard, Jr., Middlesex South, said that he had objected because the issues had not been clearly defined, but that he would not object to having a committee study the whole question.

Dr Richard M. Smith, Suffolk, then made a motion that the recommendation of the Committee on Public Relations be amended to read "The Committee recorded itself as endorsing in principle such an ascending scale of membership dues and urges that this matter be referred to a proper committee for study." The motion to amend was seconded, put to a vote and carried.

Dr Lewis S. Pilcher, Middlesex South, said that the question was already before the Committee on Membership for study and moved to table the original motion. The President called for a vote on the motion to table and, on a show of hands, declared the motion carried.

The Secretary then moved that the recommendation of the Committee concerning awards to students in the approved medical schools of the Commonwealth be approved by the Council and stated that the committee proposed to study the question and to determine the proper means to select the recipients by the Committee on Medical Education. The motion was seconded, and it was so ordered by vote of the Council.

*Committee on Arrangements*—Dr Harold G. Giddings, Middlesex South, *Chairman*

Dr Giddings presented the report of the committee, as follows:

At the stated meeting of the Council on October 1, 1947, it was voted to accept the cordial invitation of the Worcester District Society to hold the 1949 Annual Meeting of the Massachusetts Medical Society in Worcester.

This will be the first time since 1939 that the Society has met elsewhere than in Boston.

A committee of the Worcester District Medical Society, of which Dr George R. Dunlop is chairman, is working in close co-operation with the Committee on Arrangements, and plans are already well under way for the meeting, which we recommend be held at Worcester on May 23, 24, 25 and 26, 1949.

Dr Giddings moved that the report be accepted. The motion was seconded and carried.

Dr Giddings moved that the recommendation concerning time and place of the next annual meet-

ing be approved. The motion was seconded and so voted.

*Committee on Public Health*—Dr Roy J. Ward, Worcester, *Chairman*

Dr Ward pointed out as a correction that the date of the committee meeting should read "June 5" and not "July 21."

The Secretary then moved that the report and the supplementary report (Appendix No. 10) be accepted. The motion was seconded, and it was so ordered by vote of the Council. The President asked that the request of the committee to have Dr Howard B. Sprague explain the heart demonstration program be approved. On a voice vote, the Council granted this request.

The President introduced Dr Sprague, who in turn introduced Dr David D. Rutstein. Dr Rutstein, in reply to a question by Dr John F. Conlin regarding whether speakers in the program should be selected on the basis of a ratio of 1 prominent speaker to 1 or 2 less well known speakers, agreed that this method of selection was desirable. In reply to a question from a councilor regarding the charge of \$10,000 for medical education listed in the budget of the heart demonstration program, he stated that the amount referred to was for work in co-operation with the New England Heart Association and the Massachusetts Medical Society, as well as for the education of nurses, teachers and other groups concerned with the problem.

The President then asked for action on the recommendation of the committee appearing in the report as follows:

The Committee approved Dr Phippen's resolution and a motion was made and adopted that we recommend to the President of the Massachusetts Medical Society that a committee be appointed to expedite the Massachusetts "Diabetes Week" program from December 6 to 12, 1948, that this committee be empowered to act, and that its efforts be co-ordinated with Dr Ohler's Committee on Postgraduate Education. It was also moved and adopted that the Council take necessary action relative to the final paragraph of Dr Phippen's resolution.

The Secretary made a motion that the Council approve this recommendation. The motion was seconded, and it was so ordered by vote of the Council.

*Committee on Benevolence*—Dr Dwight O'Hara, Middlesex South, *Chairman*

Dr O'Hara presented the report of the Committee (Appendix No. 11) and moved the adoption of the proposal of the committee. The motion was seconded, put to a vote and carried.

Dr O'Hara then moved that the recommendation that a temporary committee on benevolence be appointed to operate until such time as the by-laws may be amended to authorize such an arrangement be approved.

until the Committee on Cancer develops and presents a system for consideration to the Council

Dr Papen moved that the recommendation of the committee be tabled. The motion was seconded. On a voice vote, the President declared the motion carried.

The Secretary then stated that he was sorry that none of the committee were present, and that it was his duty to move that the second recommendation of the Committee on Cancer—"that the Committee on Publications be encouraged to prepare a revised edition of the Cancer Manual"—be approved by the Council. The motion was seconded, put to vote and unanimously carried.

(At this time there was much discussion concerning the motion to table made by Dr Papen but the President finally ruled that any discussion was out of order.)

*Committee on Tax-Supported Medical Care—Dr Albert A Hornor, Suffolk, Chairman*

Dr Hornor presented the report (Appendix No 5) and made the following remarks:

Mr President, before speaking about the recommendations of the Committee on Tax-Supported Medical Care, I would like to remind you that the Executive Committee voted not to accept the report of the Committee. I do, however, want to have the report of the Committee approved and its recommendations adopted.

As a result of the meeting of the Committee on Tax-Supported Medical Care on July 28, 1948, the following recommendation was made to the Council that the Council of the Massachusetts Medical Society approve "Medical Care Program—Policies and Procedures, from the Office of Veterans' Services Room 123, State House, Boston, Massachusetts, effective July 15, 1948," with the inclusion of the amendment to which Commissioner O'Day has agreed as follows: "You may rest assured that after your Massachusetts Medical Society meets and approves the program, I will be pleased to notify all of my agents throughout the Commonwealth of the action, and that this approval is effective subject to renegotiation."

I think that no member of your committee would have recommended acceptance of Mr O'Day's program without that agreement to renegotiation. Several have worked on this question of tax-supported medical care for a long time, and we all know that the people down at the State House have a fixed fee for all cases throughout the State.

That very definitely has to be there. I don't see how they can operate otherwise. I think, and in fact I am aware, that the Council has voted that we do not want to cut our fees for tax-supported medical care.

Now, after all, the commissioner and his associates are willing to renegotiate any time we wish. And I think that as a part of acceptance of the Committee on Tax-Supported Medical Care it would be worth while for the Council to tell us how they would like us to renegotiate it, and how long they would like to have us try this program before we ask for renegotiation.

Mr President, I move the adoption of the recommendation of the Committee on Tax-Supported Medical Care.

The motion was seconded. At the request of Dr Elmer S Bagnall, Essex North, Dr Hornor said that the salient features were contained in an inter-departmental letter from the Office of the Commissioner of Veterans' Services of the Commonwealth, as follows:

To all Veterans Agents

Enclosed herewith is a copy of our new program of Medical-Dental care. The program is effective as of July 15, 1948.

The co-operation of all agents is urgently requested to see that this policy is carried out to the fullest degree. This program has been submitted to the Massachusetts Medical Society for approval.

Dr Bagnall then stated that it was his feeling that the whole matter should be referred back to the committee for further study of the legislation concerning veterans' medical care and old-age services. After some further discussion, Dr Alexander J A Campbell, Suffolk, moved that the whole question be laid on the table, and that a full report of the committee including the veterans' services program (Appendix No 6) be published in the *New England Journal of Medicine*. The motion was seconded, and it was so ordered by vote of the Council.

*Advisory Committee to the Red Cross Blood Bank—Dr John F Conlin, Suffolk, Chairman*

At the request of Dr Conlin, the Secretary moved that the Council approve the report (Appendix No 7). The motion was seconded, and it was so ordered by unanimous vote of the Council.

*Committee on Veterans' Affairs—Dr Harvey A Kelly, Suffolk, Chairman*

Dr Kelly moved that the report (Appendix No 8) be accepted. The motion was seconded, and it was so ordered by vote of the Council.

Dr Kelly then moved the adoption of the resolution with a change in the wording of the second paragraph as follows: "Whereas many European schools are not approved by most accredited approving bodies in the United States."

The motion was seconded and passed by a unanimous vote of the Council.

*Committee on Public Relations—Dr Harold R Kurth, Essex North, Secretary*

Dr Kurth presented the report (Appendix No 9).

The Secretary then made the motion that the committee recommendation that the Massachusetts Medical Society initiate a public-health exhibit and that the President be empowered to appoint a committee consisting of a representative from each district to initiate such a program immediately be approved.

The motion was seconded, and it was so ordered by a unanimous vote.

The Secretary then moved that the recommendation to establish a student loan fund (which had been disapproved by the Executive Committee) be disapproved by the Council. The motion was seconded, and it was so ordered by a unanimous vote.

## APPENDIX NO. 2

## REPORT OF THE EXECUTIVE COMMITTEE

A meeting of the Executive Committee was called to order at 4:00 p.m. on September 8, 1948 by the president, Dr. Daniel B. Reardon with half the members present. The officers present were, besides the President, the president-elect Dr. Arthur W. Allen, the treasurer, Dr. Eliot Hubbard and the Secretary.

## MATTERS REFERRED TO THE EXECUTIVE COMMITTEE BY THE COUNCIL IN MAY, 1948

## 1. Should the Society receive certain gifts?

Dr. Eliot Hubbard stated that the Council was not in favor of accepting monetary gifts, even though they were to be used only for charitable, scientific and educational purposes and that he was interested in the question because of the effect on the Society's income-tax status. He questioned the possible danger of accepting gifts from drug firms. Dr. Hubbard suggested that he might question the Treasury Department in a frank letter asking for information. Dr. Robert W. Buck, chairman of the Committee on Finance, stated that he could add no further information. The Secretary moved that the committee defer action until the Treasurer received replies from the American Medical Association and the Treasury Department concerning the whole matter. The motion was carried unanimously.

2. A proposal to make the Committee on Postgraduate Assembly a subcommittee of the Committee on Postgraduate Medical Education (approved by Dr. Leroy Parkins and Dr. Richard Ohler).

On a motion by the Secretary, seconded by Dr. John Curley, Worcester North, this proposal was unanimously approved by the committee.

3. A proposal to have the Society sponsor the art exhibit of the Massachusetts Physicians Art Association at the annual meeting.

Dr. Robert W. Buck pointed out that members of the Association are all fellows of the Society and that the expense to the Society would not be increased by sponsorship. Dr. Reardon stated that it would give the Woman's Auxiliary good work to do and that it would encourage art in the profession. The committee voted unanimously to approve the proposal.

4. The request by Dr. M. J. Schlesinger, Middlesex South, to establish a section on pathology among the membership of the Society.

Dr. Schlesinger stated that this was urged by the New England Pathological Society. He also said that 100 to 125 attended monthly meetings.

Dr. John Fallon, Worcester suggested that the name be "Section on Pathology and Physiology." Dr. Arthur W. Allen moved that the committee approve of the establishment of a section on pathology and physiology. This motion was seconded, and it was so voted.

5. Action on the request of Dr. Augustus Thorndike, Suffolk, that the President appoint a committee of the Society to confer with the officers and directors of the newly formed Bay State Medical Rehabilitation Clinic to consider in what manner the Society may best assist in the establishment of the clinic or clinics and to report its findings to the February meeting of the Council.

Dr. Henry Marble said he hoped the committee would favor this work of Dr. Thorndike's, and that it was an excellent private charity and had no connection with any federal agency. On a motion by Dr. John J. Curley the committee unanimously approved the appointment of such a temporary committee.

The motion was seconded, and it was so ordered by vote of the Council

Dr O'Hara moved acceptance of the report as a whole. The motion was seconded and carried.

Dr O'Hara, in answer to several questions, outlined the organization and functions of the Massachusetts Medical Benevolent Society and assured the Council that the fund would be an active one.

*Report of the Delegates to the House of Delegates of the American Medical Association*—Dr Walter G Phippen, Essex South

Dr Phippen moved for acceptance of the report as printed (Appendix No 12). The motion was seconded, put to vote and carried.

*Subcommittee on Mental Health*—Dr Walter E Barton, Norfolk, *Chairman*

Dr Barton moved for acceptance of the report (Appendix No 13). The motion was seconded, and it was so ordered by vote of the Council.

The Secretary then moved that the reports of the Executive Committee and the Committee on Public Relations as amended at this meeting be approved. The motion was seconded and so voted.

#### NEW BUSINESS

The President introduced Dr Henry A Robinson, Norfolk South, who had attended the meeting of the National Physicians Committee as a representative of the Massachusetts Medical Society. Dr Robinson said that he and Dr Howard F Root, Suffolk, the other representative, had been very favorably impressed with the work of the National Physicians Committee and that they would be glad to hear from any fellow interested in forming a state committee of the National Physicians Committee.

Dr William A R Chapin, Hampden, was recognized by the President and presented the following resolution, which had been passed by the New York State Medical Society and had been published in the *Journal of the American Medical Association*, issue of July 3, 1948: "RESOLVED, That, failing to obtain co-operation from the various Specialty Boards and hospitals, the American Medical Association is requested to withhold recognition from those hospitals which make certification by a Specialty Board a necessary qualification for appointment or promotion on a hospital staff."

Dr David L Halbersleben, Norfolk, moved that the rules be suspended for consideration and discussion of the matter. The motion was seconded, and it was so ordered by unanimous vote.

At the request of Dr Chapin, the President ruled that Dr Chapin would get both discussion and action on the question.

At this point, the President called for a recess until 2 00 p m.

The President called the Council to order at 2 00 p m and recognized Dr William Chapin.

Dr Chapin presented his arguments in favor of the resolution he had presented and moved that the Council endorse in principle the resolution as presented. The motion was seconded.

Dr Leroy E Parkins, Suffolk, moved that the Council go into Executive Session. The motion was seconded, and it was so ordered by a unanimous vote.

The motion was then discussed by Dr Bernard Appel, Essex South, Dr Parkins, Dr Howard Root, Suffolk, and Dr Lewis S Pilcher, Middlesex South, in opposition, and Dr David L Halbersleben, Norfolk, and Dr Carl Bearse, Norfolk, in favor.

The President stated the question and called for a vote by a show of hands, and announced the vote as 37 affirmative, 30 negative.

The President recognized Dr John F Conlin, Suffolk, who described the program of the New England Postgraduate Assembly and urged that there be a large attendance.

Dr Conlin also announced that the American Public Health Association would meet in Boston on November 8, 1948, and stated that all physicians are eligible for membership. He hoped that many would attend the meetings and the exhibits.

On motion duly made, seconded and voted, the meeting adjourned at 3 00 p m.

H QUIMBY GALLUPE, *Secretary*

directors of the corporation, by virtue of the positions that they hold, members of the Council

I think it was a very necessary and very wise step to take to keep a constant touch and contact between the medical group, its governing body and this corporation, created in 1940

Another important problem that should be considered is the mechanism for replacement of physicians who are members of the Board of Directors. That will be started through proper channels

We must think ahead to the time when men who have worked actively for nearly ten years on this corporation will ask for release, and it is very important that men come on who are informed about the problems and the past history of the Corporation so that proper action at all times may be taken by the representatives of the position of the Board of Directors. That is more important than possibly it might appear with the statement to the members of the Council this morning

I shall also bring up the question through proper channels of whether the by-laws should not be changed so as to have a provision established that the president of the corporation shall be a physician. We felt at times with the undefined future ahead of us that we might want that definitely stated in the by-laws. We might feel it desirable to have a layman as president of the Board of Directors. With the experience of nearly ten years, and the problems that arise it may be desirable to make certain that the president of the corporation at all times shall be a physician who of course will be a member of the Board of Directors

In the last few years a major reorganization has been made in the relation of Blue Shield and Blue Cross, which is based on the experience of many years. I think they are wise measures

The first, as outlined in this booklet that you all have received is that we have changed from our initial basic relation whereby the layman who was executive director of the Blue Cross was at the same time the Executive Committee director of the Blue Shield. At that time, we were a young and promising, we hoped, corporation, and we were not in a position to have a medical director. In the intervening years we have had the services of one of the outstanding young men in the country in this field. It seemed on the basis of this relation that, as the problems that have developed were worked out and since we now have a medical director, we should be established as two distinct corporations, with our own director, who is a physician. I think that was a very fine move and it was accepted by our Board of Directors, the Blue Shield Board of Directors and the Joint Board of Blue Shield and Blue Cross meeting together. That is now our established relation

It is still necessary, of course, to keep liaison between the two groups. That is accomplished, as you may or may not know, by the fact that there are three members who constitute interlocking members between the two groups. That number of three has been established informally by the Commissioner of Insurance as a number that shall not be exceeded

We have also established plans for joint meetings of the executive committees of the two boards of directors for problems that may arise between the two corporations, and such problems have arisen, we do need a method of resolving them, and we consider this to be the effective method of approach. We had a joint committee, but it seemed wiser that the new president eliminate that joint committee and have our joint problems discussed by meetings of the two executive committees of the boards

Now with reference to other matters, the contract, as you know, has been broadened since my last report to include medical care. That is the second step placed in this group in 1939 in the over-all planning of the evolution of the program

The next step, the problem of including services in the home and office, will certainly have to wait on time and experience. How far that should be gone into with the prospect of keeping the organization solvent is still debatable despite the ardent propaganda of some agents in Washington and some lay propagandists who believe as the Washington agents do. It is still debatable, however how far these minor services should be included in the insurance program. That certainly is a matter for time and study

We have tried to effectuate our contact with the local groups. It really takes a great deal of plugging, and in this, of course, our medical director is chiefly responsible—he has to do a good deal of plugging to keep the local committees, which were provided for in our initial setup, active and busy

The reason is chiefly that there has not been enough pertinent material that we can give to them regularly, so as to keep their teeth chewing on this problem. I do feel that, as progress is made, these local groups will be brought into ever-increasing active functioning with the central groups. And if for the present there does not seem to be too much to place in your hands when Dr. Hayden and the representatives of the corporation come into the county, please accept it as evidence that we feel that for the future the local groups will be active and are an important part of our over-all functioning organization

Furthermore to keep our contacts locally active and to help the physicians, as you know, we have had periodic meetings with the physicians' secretaries, who were informed of our functions and our program

Another change since the previous report has been the shifting of the method of claim by the physicians. We moved from the activating of claims from the hospital, where a good many problems were raised and a good many inconveniences created for the physicians, to the initiation of claims directly by the physician. That was done in our local area first in one county, and it did seem to be an improvement and then it was placed on a state-wide basis. If there are difficulties, it is still in its early stage of development and I hope you will bear with us, and certainly constructive criticism will be appreciated

I think the physician should keep in mind that the complicated problems of administration have been greatly simplified which in turn has reduced costs of administration, and that will also be a major responsibility of our group—to keep administrative costs at the lowest point possible

The local problems that arise from this new method of initiating claims I think, may be placed in the hands of the hospitals. I believe we must have all hands thoroughly imbued with the need to create smooth functioning. Before we put this on a state-wide basis, we approached all the hospitals, and the administrators were only too happy to co-operate right straight across the State. The problem is the changing personnel in hospitals. Two out of three office administrators may carry this through, whereas the third either may not understand or may fail to grasp its importance, and I think that most of the trouble has probably arisen from such lack of understanding, which I think time will resolve

The financial situation continues satisfactory. We are still operating in the black with a substantial surplus, which is required by good actuarial planning. This group, in its wisdom on the recommendation of a committee of the Council, raised the income level for eligibility for service to \$3000

This demonstrates that the physician can put the problem of cost of medical care on a proper base. It was a very sound strategic move as well as, I think, a perfectly proper move with reference to the needs of the people

The question of fee schedule has again been studied by a committee of the Society, Dr. McAttrick's fee-schedule committee, which has a very large representation from across the State. It was felt that at present it was not strategic to make any change in the fee schedule, and this was talked over very thoroughly and the decision was arrived at with reference to three pertinent problems: the major objective of proving that the physician on a voluntary basis can handle this problem of prepaid medical care from the solvency of the corporation, it can be seen that we are running it satisfactorily as far as the finances are concerned, but it was very apparent that an increase in the fee schedule at the present time could not be accomplished without an increase in premiums, and, with the squeeze that the people are subjected to and the inflationary prices at the present time and the declining enrollment rate, it seemed definitely poor judgment in the opinion of this committee to advise the change of fee-schedule rates

As you know, with reference to income limitations for service and with reference to items such as fee schedules the Blue Shield group adopted a policy of referring the matter to the Society, and a committee of the Society advises how to proceed. It is felt that this group, small as it is, is wholly

6 The question of a standing committee on medicolegal testimony (The former Committee to Consider Expert Testimony had recommended that the by-laws be amended to produce such a standing committee.)

The Secretary pointed out that the chief purpose of the committee would be to discover improper testimony by fellows of the Society at various trials for malpractice cases and that such questions of ethics might well be referred by anyone to the Committee on Ethics and Discipline. The President pointed out that the suggestion of appointing listeners at trials might include all cases in which medical testimony is given.

On a motion by Dr Lawrence R Dame, Franklin, seconded by Dr Curley, Worcester North, the committee voted unanimously not to approve the request to amend the by-laws to produce a standing committee on medicolegal testimony.

## COMMITTEE REPORT

### Committee on Membership

The Committee met on August 24, 1948, and the Secretary submitted the report, which concerned requests for retirement and resignations and those fellows deprived of membership for nonpayment of dues. With a few minor corrections submitted by the Treasurer, the Executive Committee accepted the report.

## NEW BUSINESS

The Secretary read the following resolution submitted by the Hampden District Medical Society:

WHEREAS, Hospital trustees in order to maintain and insure the best possible care of patients in their institutions are increasingly demanding certification in specialties and/or membership in certain national colleges or specialties and,

WHEREAS, It has come to our attention that an irregular situation exists in selection of candidates for membership in the aforesaid organizations, such as the exclusion of candidates from membership by prejudiced local fellow workers followed by the acceptance of some of these men through the intercession of more celebrated practitioners in other areas and,

WHEREAS, We have examples here of failures in board examination followed by marking up of these examinations to an acceptable figure when the mortality of the examination has hit influential and responsible leaders of that particular field of medicine,

The Hampden District Medical Society, at its annual meeting on April 27, 1948, petitions the Executive Committee of the Massachusetts Medical Society for the appointment of a committee to investigate such irregularities and evidences of partialities so that personalities may be further minimized and candidates for the organizations mentioned above be treated in an equal and fair manner, such committees to hold hearings and report back to the Society at an early date and the Hampden District Medical Society be later informed of any action which is taken on this resolution.

The Secretary stated that he believed the Committee on Ethics and Discipline could handle any situation that might arise in this regard.

Dr John J. Curley moved that the matter be laid on the table until the next meeting of the committee. There was a second, and the motion was carried unanimously.

The Secretary read a communication from the Section on Physiotherapy requesting a change of name to "Section on Physical Medicine." On motion duly made and seconded the committee voted unanimously to recommend the change requested.

The Secretary reported the program of the House of Delegates of the American Medical Association to select a candidate for the General Practitioners Award at the interim session, suggested that the Massachusetts Medical Society ought to take steps to select the outstanding general practitioner in Massachusetts in 1949 and asked for permission to notify the district secretaries to present names of candidates to the Executive Committee in time for the interim

session in 1949. On motion made and seconded the committee gave unanimous permission.

Dr Reardon then related a request from Mr Twomey of the firm of Palmer-Dodge, our attorneys, to have the Society adopt the attitude of *amicus-curiae* and approve of a brief submitted to the court by our attorneys in the case of a physician in the western part of the State who had been sued by a patient for allegedly instituting the narcotic habit. Dr Reardon stated that the Berkshire District Medical Society was much upset by the case and that the doctor concerned was held in high esteem. On motion of the Secretary the Committee voted to support Mr Twomey's request to send such a brief to the Supreme Court.

## REPORTS OF COMMITTEES IN CIRCULAR OF ADVANCE INFORMATION

### Committee on Cancer

The Executive Committee voted to approve the recommendations of the committee beginning on page 1, line 27.

The Executive Committee voted to approve the recommendation of the committee beginning on page 2, line 4.

### Committee on Tax-Supported Medical Care

After considerable discussion the Executive Committee by a small majority voted not to approve the recommendation that the "Medical Care Program" of the Office of Veterans' Services of Massachusetts be approved by the Society.

### Advisory Committee to the Red Cross Blood Bank

The Executive Committee voted unanimously to approve the request of the committee beginning on page 4, line 19.

### Committee on Veterans' Affairs

The Executive Committee voted unanimous approval of the resolution beginning on page 5, line 16.

### Committee on Public Relations

The Executive Committee voted unanimously to approve of the recommendation found in the motion beginning on page 6, line 33.

The Executive Committee voted to disapprove of the resolution of the committee beginning on page 7, line 4 (Dr Hubbard had stated that he believed students would be poor risks.)

After hearing from Dr John Conlin concerning the statewide health meeting to be held early in 1949, the Executive Committee voted unanimously to approve the action of the committee beginning on page 7, line 33.

After hearing from the Treasurer and the Secretary the Executive Committee voted unanimously to disapprove of the action of the committee beginning on page 8, line 33.

The Executive Committee approved the recommendation of the committee beginning on page 8, line 46, and recommended that the Committee on Medical Education be the committee to handle the matter.

### Committee on Public Health

The Executive Committee approved the recommendation of the committee beginning on page 10, line 49.

The Executive Committee voted approval of the recommendation beginning on page 11, line 43.

The Executive Committee also voted approval of the last paragraph of Dr Phippen's resolution beginning on page 12, line 39.

### Committee on Benevolence

The Executive Committee unanimously voted approval of the recommendation beginning on page 13 line 9, the proposal of the committee and the recommendation beginning on page 14 line 4.

The meeting was adjourned at 6 10 p.m.

H. QUIMBY GALLUPE, Secretary

## APPENDIX NO 3

### AFFAIRS OF BLUE SHIELD

In the past few years basic changes have been taking place in our organization. This group has seen fit in its wisdom to make the president of the corporation and the medical

sufficient data for a report on this point. In the meantime it is suggested that in all cases of vague or ill defined gynecologic signs or symptoms with no obvious abnormality to account for them found on pelvic examination, the vaginal smear be used as an additional means of diagnosis.

During this past year, with the aid of the Massachusetts Division of the American Cancer Society, lectures on cancer were provided for each of the district societies. Its interest in the lectures varied, and it is hoped that the most effective method for presentation of points of diagnostic and therapeutic value can be evolved.

SHIELDS WARREN, *Chairman*  
THOMAS J. ANGLEM  
ALLEN G. RICE  
CHANNING C. SIMMONS

## APPENDIX NO 5

### REPORT OF THE COMMITTEE ON TAX-SUPPORTED MEDICAL CARE

As a result of the meeting of the Committee on Tax-Supported Medical Care on July 28, 1948, the following recommendation was made to the Council that the Council of the Massachusetts Medical Society approve — "Medical Care Program — Policies and Procedures, from the Office of Veterans' Services, Room 123, State House, Boston, Massachusetts Effective July 15, 1948," with the inclusion of the amendment to which Commissioner O'Day has agreed as follows:

You may rest assured that after our Massachusetts Medical Society meets and approves the program, I will be pleased to notify all of my agents throughout the Commonwealth of the action, and that this approval is effective subject to renegotiation.

ALBERT A. HONOR, *Chairman*  
FREDERICK S. HOPKINS  
FRANCIS P. MCCARTHY  
FRANK W. SNOW

## APPENDIX NO 6

### MEDICAL CARE PROGRAM OFFICE OF VETERANS' SERVICES

#### PURPOSE

A recent survey discloses a large amount of apparently unnecessary medical expense having been incurred with a corresponding increase in medical cost. Because of this, it is imperative that policies for procedures and cost control be adopted. It is not our intention to curtail necessary medical care, but only to provide a needed uniform plan of payment for those items of medical care furnished to all persons accepted by the Office of Veterans' Services. It is your responsibility to see that this plan is carried out. The following are the instructions:

#### 1 Physicians' Services

##### 1 Eligibility

When physicians' services are needed, payment will be provided as an addition to the regular budget. On temporary cases such payment is not to be encouraged unless an emergency arises.

##### 2 Authorization

Permanent recipients will be allowed two visits in any one month by a physician. Additional visits thereafter must be authorized by the Local Agent and substantiated by a written statement from the physician giving the diagnosis, prognosis, and an estimate of the number of calls necessary to complete the treatment.

##### 3 Fee Schedule

The following uniform fee schedule is to be hereafter adopted by this Office:

Office Visit — \$2.00  
Home Visit — \$3.00

#### Multiple Visits

When more than one patient is seen during one call at the office, home, or nursing home, full fee will be allowed for the first visit. Thereafter, full fee for one patient and \$1.00 for each additional patient.

*Travel Allowance* — \$2.00 extra in rural communities where the physician is compelled to travel a considerable distance.

*Night Calls* — \$1.00 additional, between 11 p.m. and 7 a.m.

**NOTE** — Extra fees for medication, either home or office visit, will not be allowed unless fully explained and approved by this Office.

## II Hospitalization

### 1 Eligibility and Notice

Eligibility for hospital remains as heretofore and will be provided only when financial need exists.

All Agents must notify this Office within three (3) days following the entrance of an applicant into a hospital, either by letter or application, and this must be followed by a thorough investigation by the Local Agent to determine if financial need exists. This investigation should disclose all available resources of the applicant and whether part or all of the expense can be paid either by the applicant or by members of the family.

If the applicant has Blue Cross, or Blue Shield or any other hospital insurance, this must be used before hospital expense will be assumed by this Office.

#### A General Policy Re "Service" Care

All recipients or applicants for Veterans Benefits who apply for hospitalization must be immediately notified by you that only "service" care in a ward will be provided.

##### (1) Definition

"Service" care is defined as care in hospitals where the staff of physicians provides free medical treatment and/or surgery to ward patients. Therefore, no fees for doctors are allowed.

##### (2) Rate of Payment

Payment through this Office to a hospital will be provided at a maximum daily all-inclusive rate not to exceed \$8.00 per day.

##### (3) Hospital Extras

Certain hospital cases may require unusually expensive drugs such as streptomycin or large quantities of penicillin. Individual consideration will be given to such extras as charged by the hospital, but to no other extra charges submitted, such as use of operating room, laboratory fees, etc.

Charges for blood transfusions will not be allowed. Any necessary blood will be provided through this Office in exchange for any used by the hospital and given to the recipient. In hospitals west of the City of Worcester, this Office will not be able to provide this blood at the present time. Blood banks will be used in that area soon after July 1st, 1948.

##### (4) Notice to Hospitals and Physicians

All Agents on receiving these instructions must immediately contact the hospitals in their district and notify them of the above policy. The attending physician must be notified, either by the applicant or by the Agent, that Veterans' Benefits patients are to enter hospitals under the above-specified "service" care plan, and that no allowance will be provided for the care furnished by a doctor in the hospital.

capable of arriving at a decision regarding such pertinent matters

How about public relations? We have in conjunction with the Blue Cross engaged the services of a very effective public-relations man, and I think that you have been aware through the newspapers of more activity and a more active effort to enlighten the public about our methods and our objectives. There is one matter that is very vital with reference to public relations. It is subtle and more apparent to those involved in the work in your behalf than to the individual practitioner. There is the question of enough instances to disturb management, to disturb the public, of an excessive differential charge by the physician, in the instance of the patient who is just a little above the level of the income set by this Council. That problem is under study by the Fee Schedule Committee, and of course is a matter in which Blue Shield would not take any action unless instructed by the Committee or the Council, which means, of course, that it will be referred to the Council until we are advised on how to proceed. It is a matter that should be considered very seriously because public relations in the end are going to determine the failure or success of these voluntary prepaid ventures. Our current problems are definite, and of course we hope they will be resolved.

Everybody will make an effort to see that the problems are resolved fairly in the interest of everyone involved. As you know, from the circularized statement, we have had a year and a half of no growth in Blue Shield, and this has also been somewhat characteristic of Blue Cross. Some of the difficulties that confronted Blue Cross a year and a half ago arose primarily from the forces of inflation, and resulted in temporary financial difficulties for that organization. That, of course, held up growth of both corporations. That was inevitable, and the problem is to get the good ship of voluntary prepayment back into the water and under sail. That is the difficulty at this time. It will take judicious consideration of all problems involved, and it will require a very definite stand in protection of the basic principles on which we have dealt.

Now, we are moving definitely toward a solution of those problems, and I am sure of that because I think we must assume that there is goodwill on all sides. Basically, the problems are different, and they have got to be talked out very frankly and resolved across the board, and to that end the two executive committees of the respective corporations are meeting tomorrow night, from that meeting we may achieve the very close and confidential co-operation that, up until a year and a half ago, existed between the two corporations. And from that confidential co-operation all current problems may be effectively resolved, and then we may see more active sales for both corporations. We must realize that this movement is under very close scrutiny, as shown in the hearings last spring in Washington, and basic error or failure to grow or failure to meet the needs of the people, or any demonstration of anything but full capacity in meeting the problems and administering them, will put us in a very vulnerable position, so I am sure all parties involved will devote themselves to resolving all current problems, and our hope and belief is that this will be accomplished.

Regarding the question of competition from commercial insurance companies, it might be that Dr Hayden could give that better in figures. I will say that it is very definite and serious. Our only strength was in the service contract, in addition to the fact that operating on a nonprofit basis we should have been able to offer a better contract than the commercial companies. At present I think it is fair to say that with reference to the present hospitalization contract, it can be met by commercial insurance companies, but there is also this fact, which must always be kept in mind: the commercial insurance groups will only move into large groups. They will not take the small groups, which Blue Cross does give service to. They also have pretty excessive enrollment requirements, almost always 75 per cent, and when there is a revamping of the Blue Cross program, the Blue Cross may be able to write a commercial contract that competes favorably. Our program can still compete because the commercial insurance companies can never offer the physician services on a service basis, and I am sure we can work down the financial basis, if we maintain a fee schedule within the present limit that the companies cannot compete with, as far as treatment is concerned.

## APPENDIX NO 4

### REPORT OF THE COMMITTEE ON CANCER

The Committee met on August 9, 1948, with Drs John Conlin, Arthur W. Allen, Thomas J. Anglem, Channing C. Simmons and Shields Warren present.

The problem of the registration of cancer cases was considered. Both compulsory and voluntary registration of cancer cases has been tried. The compulsory registration is far from effective. At present 12 states have some type of cancer registration. The objectives of a registration system are to obtain adequate information regarding the size of the cancer problem and its nature and to obtain information that will be of advantage from the standpoint of better understanding of the factors of importance in etiology. Registration should also greatly improve follow-up systems. Registration in itself is of little value. The use that is made of the registered cases is of importance.

The chief advantage for the patient is that it will aid in encouragement of periodic follow-up examinations. The three potential sources of registration are private practitioners, clinics and hospitals and laboratories of pathology.

The best and most effective source is the private practitioner. The compulsory-registration system has proved to be somewhat ineffective. Unless there is full co-operation of all interested, no real value would be obtained from the mere fact of registration.

It is therefore recommended that the Massachusetts Medical Society endorse the principle of voluntary registration of cancer cases and that the Committee on Cancer be instructed to develop a system for consideration by the Council.

In 1940 the Committee on Publications, an offshoot of the American Cancer Society and the group in Massachusetts interested in cancer control, prepared a manual on cancer for the general practitioner. This was distributed by the Massachusetts Department of Public Health to all practitioners in the State, and a number of copies were sold outside the State.

The total edition was approximately 14,000 copies. There still continues a demand for this volume, but in the eight years that have elapsed, considerable advances in the knowledge of cancer have taken place. The Committee on Publications, of which Dr Channing C. Simmons is chairman, has expressed its willingness to prepare an up-to-date edition of this manual.

It is recommended that the Committee on Publications be encouraged to prepare a revised edition of the *Cancer Manual*.

Of considerable interest is the amount of money being raised for cancer and spent for cancer in Massachusetts.

In the period from September 1, 1947, to August 10, 1948, the Massachusetts Division of the American Cancer Society received \$519,336.69. During that period the national society made grants totaling \$457,204 in Massachusetts, and the Massachusetts Division made additional grants totaling \$273,325.90, a grand total of \$730,529.90, or \$211,193.21 more money made available for service and research in Massachusetts than was raised here.

In addition, construction grants of over \$1,000,000 were made by the United States Public Health Service for the construction of cancer facilities, and several hundred thousand dollars were made available for research in Massachusetts. The federal Government made \$75,286 available for cancer to the Massachusetts Department of Public Health in the fiscal year 1948.

Great interest has been aroused during the year in the vaginal-smear method of diagnosis of cervical and uterine cancer, particularly by ill advised advertising in newspapers and lay periodicals. The Committee on Cancer has studied the problem regarding whether vaginal-smear diagnosis should be encouraged as a routine procedure in pathological laboratories. At the present time, it is our belief that further work needs to be done on the evaluation of the test before a definite statement can be made.

There is no question that the vaginal-smear examination offers an added means of diagnosis of cancer of the female genital tract—perhaps the best means in certain types of cases. We are not yet sure that the time and money consumed in making a routine vaginal smear in every woman of cancer age are warranted. We hope in another year to have

sufficient data for a report on this point. In the meantime it is suggested that in all cases of vague or ill defined gynecologic signs or symptoms with no obvious abnormality to account for them found on pelvic examination, the vaginal smear be used as an additional means of diagnosis.

During this past year, with the aid of the Massachusetts Division of the American Cancer Society, lectures on cancer were provided for each of the district societies. Its interest in the lectures varied and it is hoped that the most effective method for presentation of points of diagnostic and therapeutic value can be evolved.

## APPENDIX NO. 5

### REPORT OF THE COMMITTEE ON TAX-SUPPORTED MEDICAL CARE

As a result of the meeting of the Committee on Tax-Supported Medical Care on July 28, 1948, the following recommendation was made to the Council that the Council of the Massachusetts Medical Society approve — "Medical Care Program — Policies and Procedures, from the Office of Veterans' Services, Room 125, State House, Boston, Massachusetts Effective July 15, 1948," with the inclusion of the amendment to which Commissioner O'Day has agreed as follows:

You may rest assured that after your Massachusetts Medical Society meets and approves the program I will be pleased to notify all of my agents throughout the Commonwealth of the action and that this approval is effective subject to renegotiation.

ALBERT A. HONOR, *Chairman*

FREDERICK S. HOPKIN

FRANCIS P. MCCARTHY

FRANK W. SNOW

## APPENDIX NO. 6

### MEDICAL CARE PROGRAM OFFICE OF VETERANS SERVICES

#### PURPOSE

A recent survey discloses a large amount of apparently unnecessary medical expense having been incurred with a corresponding increase in medical cost. Because of this, it is imperative that policies for procedures and cost control be adopted. It is not our intention to curtail necessary medical care, but only to provide a needed uniform plan of payment for those items of medical care furnished to all persons accepted by the Office of Veterans' Services. It is your responsibility to see that this plan is carried out. The following are the instructions:

#### I Physicians' Services

##### 1 Eligibility

When physicians' services are needed, payment will be provided as an addition to the regular budget. On temporary cases such payment is not to be encouraged unless an emergency arises.

##### 2 Authorization

Permanent recipients will be allowed two visits in any one month by a physician. Additional visits thereafter must be authorized by the Local Agent and substantiated by a written statement from the physician giving the diagnosis, prognosis, and an estimate of the number of calls necessary to complete the treatment.

##### 3 Fee Schedule

The following uniform fee schedule is to be hereafter adopted by this Office:

Office Visit — \$2.00

Home Visit — \$5.00

#### Multiple Visits

When more than one patient is seen during one call at the office, home, or nursing home, full fee will be allowed for the first visit. Thereafter, full fee for one patient and \$1.00 for each additional patient.

*Travel Allowance* — \$2.00 extra in rural communities where the physician is compelled to travel a considerable distance.

*Night Calls* — \$1.00 additional, between 11 p.m. and 7 a.m.

*NOTE* — Extra fees for medication, either home or office visit, will not be allowed unless fully explained and approved by this Office.

## II Hospitalization

### 1 Eligibility and Notice

Eligibility for hospital remains as heretofore and will be provided only when financial need exists.

All Agents must notify this Office within three (3) days following the entrance of an applicant into a hospital either by letter or application and this must be followed by a thorough investigation by the Local Agent to determine if financial need exists. This investigation should disclose all available resources of the applicant and whether part or all of the expense can be paid either by the applicant or by members of the family.

If the applicant has Blue Cross, or Blue Shield or any other hospital insurance, this must be used before hospital expense will be assumed by this Office.

#### A General Policy Re "Service" Care

All recipients or applicants for Veterans' Benefits who apply for hospitalization must be immediately notified by you that only "service" care in a ward will be provided.

##### (1) Definition

"Service" care is defined as care in hospitals where the staff of physicians provides free medical treatment and/or surgery to ward patients. Therefore, no fees for doctors are allowed.

##### (2) Rate of Payment

Payment through this Office to a hospital will be provided at a maximum daily all-inclusive rate not to exceed \$8.00 per day.

##### (3) Hospital Extras

Certain hospital cases may require unusually expensive drugs such as streptomycin or large quantities of penicillin. Individual consideration will be given to such extras as charged by the hospital but to no other extra charges submitted, such as use of operating room, laboratory fees, etc.

Charges for blood transfusions will not be allowed. Any necessary blood will be provided through this Office in exchange for any used by the hospital and given to the recipient. In hospitals west of the City of Worcester, this Office will not be able to provide this blood at the present time. Blood banks will be used in that area soon after July 1st, 1948.

##### (4) Notice to Hospitals and Physicians

All Agents on receiving these instructions must immediately contact the hospitals in their district and notify them of the above policy. The attending physician must be notified, either by the applicant or by the Agent, that Veterans' Benefits patients are to enter hospitals under the above-specified "service" care plan, and that no allowance will be provided for the care furnished by a doctor in the hospital.

### B Policy Re Hospitals Where Free "Service" Care Is Not Available

The basic policy of this Office is to use those hospitals providing free "service" care to ward patients to the fullest extent wherever possible throughout the State. However, this Office recognizes that there are certain areas in the State, chiefly rural, where there are no hospitals in the vicinity in which the staff of physicians gives free care to ward patients.

Therefore, when there is no hospital within a fifteen-mile radius of the recipient's town where such free medical or surgical service for ward patients is available, recipients of Veterans' Benefits may be admitted to the local hospital and this Office will provide payment to the attending physician or surgeon at Blue Shield rates. It is important to note that the Blue Shield rate for an operation includes the fee for the assistant surgeon. No extra payment to an assistant will be allowed by this Office. A fee for the anesthetist within Blue Shield rates will be allowed.

The above-outlined policy (regarding the all-inclusive rate not to exceed \$8.00) as paid to the hospital for hospital care will remain in effect and have no bearing on this plan to pay for physicians' services.

### NOTICE TO BE GIVEN HOSPITALS, DOCTORS AND RECIPIENTS

All Agents, on receiving these instructions, must immediately contact the hospitals in their district and notify them of the above policy. The attending physician must be notified either by the Agent or by the recipient that only ward care will be provided through this Office.

Payment for physicians' fees will be made in the following list of hospitals only:

Plunkett Memorial Hospital	Adams
Farren Memorial Hospital	Montague
Franklin County Public Hospital	Greenfield
Fairview Hospital	Great Barrington
North Adams Hospital	North Adams
Wing Memorial Hospital	Palmer
Mary Lane Hospital	Ware
Community Memorial Hospital	Ayer
Webster District Hospital	Webster
Emerson Hospital	Concord
St. Luke's Hospital	Middleboro
Claffin Hill Hospital	Milford
Norwood Hospital	Norwood
Jordan Hospital	Plymouth
Cape Cod Hospital	Hyannis
Tobey Hospital	Wareham
Nantucket Cottage Hospital	Nantucket
Martha's Vineyard Hospital	Oak Bluffs
Winchendon Hospital, Inc.	Winchendon

### FEES ALLOWED

1 For medical care cases where no surgery is involved (as in pneumonia, etc.) the allowed fee for the attending physician in the above-listed hospitals will be \$4.00 for the first visit in the hospital and \$2.00 for each visit thereafter. During any one hospital stay, for the first two months the total fee to be paid the physician shall not exceed \$150.00.

2 For surgical care in these above-listed hospitals this Office will provide payment at Blue Shield rates.

NOTE — Veterans seeking hospitalization must avail themselves of facilities offered by the Veterans' Administration and the Soldiers' Home in Chelsea. On temporary cases, hospitalization will not be considered unless they are emergencies. Applicants must assume the responsibility of temporary hospitalization bills when they return to work.

### III Drugs

The purchase of medicines and other supplies through local drugstores has been much abused in many localities. From the effective date of this order only those medicines, or drugs, or supplies that have been prescribed by a physician will be accepted as legitimate charges. Whenever possible, the physician should be asked to prescribe U.S.P. (United States Pharmacopeia) or N.F. (National Formulary) drugs because of the economy that would result without loss of efficiency. If the patient is still under care for the same illness as when a medicine is prescribed, refills may be authorized. Refills on prescriptions written over a six months' period previously will not be allowed. Local Agents are required to instruct recipients that all drugs or orders for supplies are hereafter to be authorized by the Agent before their purchase.

Ordinary medicine chest supplies, such as aspirin, band-aids, disinfectants, etc., must be purchased from the allowance under personal needs as contained in our budget.

Itemized bills must be submitted in duplicate by the drugstore to the Local Agent and one copy sent to this Office. These must show the name of the purchaser, the date purchased, and the names and quantities of drugs. Current cases, where the purchase of drugs has already been authorized, will continue under the same policy as heretofore without any impairment of service. Bills for such medication already authorized will be submitted as outlined above.

### A Clinics and Out-Patient Services

Agents must advise applicants of Veterans' Benefits to take advantage of available out-patient clinics or other type of clinics. Admission fees as charged by the clinics to persons who may be classed as being in these circumstances will be allowed, except in the case of tax-supported hospitals and clinics where this Office is not legally committed to pay.

Veterans who are eligible for out-patient treatment at a Veterans' Administration hospital or through a Veterans' Administration contract doctor must use this type of service in preference to any service available through this Office to non-service connected disability cases.

### B Visiting Nurse Service

The fullest use of the Visiting Nurses must be employed wherever they are available. Agents should consult the physician regarding the advisability of delegating appropriate tasks whenever possible. The prevailing community rate charged by the Visiting Nursing Association per visit will be allowed by this office for eligible cases.

### Family Responsibility

It is noted on many of our cases that members of the family have been contributing to the medical expenses of the applicants. This policy should be continued and encouraged.

### Agents' Authorization Notice

Medical bills not in excess of \$10.00 a month shall be submitted only at the termination of a two months' period with a copy of the bills. Before they are charged on the monthly returns, authorization must be made by this office. All medical bills must be submitted within sixty days.

### Physical Examination

In cases where there is a question of an applicant's ability to work, this office will authorize a medical bill for a physical examination. The Agent should authorize two or more doctors from which the applicant may select one for such an examination.

*Special Nurses*

Special nurses will be provided for only in cases when the applicant is in such an extremely dangerous condition that the attending physician orders this additional service. Agents must notify the Commissioner by telephone for this special service.

*Enforcement*

The foregoing rules must be adhered to by all Veterans' Agents if you anticipate reimbursement by this office. They will be amended or changed only by official order or authority by the Commissioner.

By order of

HENRY V O'DAY, Commissioner  
Office of Veterans' Services

State House  
Boston, Massachusetts

is permissible only as a life-saving measure when other adequate measures are not possible.

The Committee advocates that the use of pooled plasma, unless processed by current methods of inactivating the virus of hepatitis be abandoned except under the rare instance noted above. The assistance of the Committee on Postgraduate Medical Education is requested in bringing this to the attention of all physicians.

At the next meeting of the Committee it is planned to request the attendance for information and consultation representatives of the Massachusetts Hospital Association, officials of the American Red Cross Blood Program and representatives of the American Association of Blood Banks and of the Greater Boston advisory group of blood-bank directors.

F HAROLD ALLEN  
STEPHEN BROWN  
WILLIAM B CASTLE  
WILLIAM P MURPHY  
JOSEPH E ROSS  
C STUART WELCH

## APPENDIX NO 7

REPORT OF THE ADVISORY COMMITTEE TO THE RED CROSS  
BLOOD BANK

On July 28 a meeting of the Advisory Committee to the Red Cross Blood Bank was held at 8 Fenway.

Present were Dr John F Conlin, chairman, Dr F Harold Allen, Dr Stephen Brown, Dr Joseph E. Ross, Dr C Stuart Welch, Dr Arthur W Allen and Dr H Quimby Gallupe.

Some difficulty was experienced in determining the background of the appointing of this committee and the scope of its work. Many of the key persons having information on these matters were not available for consultation prior to the committee meeting.

The question was raised concerning Rh typing of blood collected by the American Red Cross and processed at the laboratory operated by the Massachusetts Department of Public Health. Funds have been made available for the Rh typing of this blood and Rh typing of prenatal blood specimens continues.

Recently publicized shortages of blood for transfusion purposes were discussed. It was agreed that increased publicity concerning the aims of the American Red Cross blood program in Massachusetts is needed. The co-operation of physicians in this matter is urged.

The House of Delegates of the American Medical Association has twice approved the Red Cross National Blood Bank Program "in principle." In June, 1948 more specific action was taken by the House of Delegates. Among items there approved were the following: local control of blood banks must rest with the county medical society; no publicity is to be released except by mutual consent of the local medical society and of the local Red Cross chapter; differences of opinion should be arbitrated by joint committees from the state medical society and from the American Red Cross; and finally "any provision of free medical service or supply without regard to ability to pay violates the principle that it is each individual's responsibility to assume the obligations of medical expenses just as he does for other living expenses. We deplore the use of the term 'free blood' in Red Cross publicity."

Discussion was had concerning privately operated blood banks notably in hospitals. Some institutions have shifted to the statewide program. It is understood that there is no attempt to interfere with continuing operation of private blood banks.

There is considerable confusion in the mind of the public as the result of recent appeals for blood through the press and radio. Numerous organizations, hospitals, veterans groups and others, in addition to the American Red Cross have made public appeals for donations of blood.

The problem of the use of pooled plasma was discussed. In certain instances the use of surplus wartime-collected plasma continues. Recent studies show that the incidence of virus hepatitis following the use of such plasma is approximately 4 per cent. It is or should be common knowledge among physicians that virus hepatitis is by no means a benign disease and that fatal cases do occur. The American Red Cross has sent out letters advising the return of surplus plasma which has been distributed. The use of such pooled plasma

## APPENDIX NO 8

## REPORT OF THE COMMITTEE ON VETERANS' AFFAIRS

The committee met at 8 Fenway August 4 1948 with Drs. Harvey A Kelly, chairman, Kenneth A Brown, Samuel Bachrach, John M Barry, John F Conlin, Arthur W Allen and H Quimby Gallupe present.

A brief report was rendered by officers of the Society concerning matters affecting veterans returning from military service during the past two years. A report was rendered on services that have been available and have been utilized by returning veterans through the Society headquarters.

The Selective Service Act of 1948 as set forth in Public Law 759 Eightieth Congress was briefly discussed. Current demands of the military services for medical officers were also discussed as informational matters.

Certain matters pertaining to the Veterans Administration and its relations to veterans and to physician veterans were discussed as orientation for the new committee.

The need for certain courses and assistance to physician veterans working for qualification for membership in various specialty boards was discussed. As data on this matter are accumulated they will be referred to the Committee on Medical Education.

The matter of Veterans Administration approval of foreign medical schools for veterans under the G I Bill was discussed. It was unanimously agreed that such a situation should be given the widest possible publicity as leading toward a situation that would jeopardize current standards of medical education.

The following resolution was adopted:

The Committee on Veterans Affairs of the Massachusetts Medical Society meeting at 8 Fenway Boston on August 4, 1948 unanimously presents the following resolution for adoption by the Council of the Society at its meeting on October 6, 1948:

WHEREAS It has been brought to the attention of the committee through an article appearing in the May 1, 1948 issue of the *Journal of the American Medical Association* and again by a letter to the Editor of the *New England Journal of Medicine* in the issue of July 22, 1948 written by Dr A J A Campbell a fellow of the Society, that the Veterans Administration in Washington is advising veterans that they may attend any medical school in Europe at the expense of the Government and

WHEREAS Such European schools are not approved by any accredited approving body in the United States and

WHEREAS Such European schools have not been approved by the approving authority for medical schools in this Commonwealth and

WHEREAS It follows that graduates of such European schools would not be eligible for examination for registration in Massachusetts and

WHEREAS, To permit such graduates to become eligible for examination in Massachusetts would lower the high standards of medical licensure already established in Massachusetts by the present medical practice act, therefore be it

RESOLVEN, That the Council of the Massachusetts Medical Society protest against the present policy of the Veterans Administration in this respect, and be it further

RESOLVEN, That a copy of this resolution be sent to the Veterans Administration and all other interested parties and organizations

GEORGE S REYNOLDS

## APPENDIX NO 9

### REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The meeting of the Committee on Public Relations was held at the Harvard Club at 6:00 p.m. on August 4, 1948. In addition to the representatives of thirteen district societies there were present President Daniel B. Reardon, chairman, Dr. Arthur W. Allen, president-elect, Dr. H. Quimby Gallupe, secretary of the Society, Dr. John F. Conlin, director of medical information and education, and Mr. Robert St. B. Boyd, executive secretary.

The report of the Secretary as printed in the advance notice of the meeting of the Council on May 24, 1948, was accepted.

President Reardon read a letter from Dr. Howard F. Root, Suffolk District, in which Dr. Root suggested to the Committee on Public Relations that the Massachusetts Medical Society initiate a "Health Week Program" in November of 1949. This "Health Week Program" would consist essentially of a public exhibit of the most recent advances in medicine, emphasizing preventive medicine as well as treatment. Allied organizations such as the Massachusetts Department of Public Health, the State Nurses' Association, the State Hospital Association and particularly the Woman's Auxiliary of the Massachusetts Medical Society would be invited to take an active part in such a program.

Dr. Bernard Appel, Essex South, stated that the City of Lynn has had such a health exhibit annually for the past fifteen to eighteen years. It was his opinion that there was much public interest in this type of medical educational program. Many of the civic organizations such as the service clubs and parent-teachers' associations lent active support in the conduct of the Lynn program.

Because of the amount of preparation that would be necessary in the initiation and creation of such a health exhibit, it was felt that a program of this type would require at least a year of preparation, hence the date, November, 1949.

A motion was made by Dr. Henry A. Robinson, Norfolk South "that the Committee on Public Relations recommend to the Council that it initiate such a public-health exhibit" and "that the president of the Massachusetts Medical Society be empowered to appoint a committee consisting of a representative from each district to initiate such a program immediately."

The motion was unanimously carried.

Dr. Howard F. Root, Suffolk, called the attention of the Committee to the problem of how to meet the needs of medical students in the future when the G. I. Bill of Rights ceases to function. It is evident that within a measurable period many students in medical schools who are at present receiving support from the United States Government will be in need of some financial assistance in order to complete their medical education. The Committee on Public Relations is well aware of the fact that the establishment of a loan fund for medical students by the Massachusetts Medical Society represents a change in fundamental policies but nevertheless considers it to be good public relations. This committee therefore endorsed the following resolution "That the ques-

tion of the establishment of a student loan fund be referred to the Council for its serious consideration."

As a matter of information, President Reardon reported to the Committee that Dr. Howard F. Root has been appointed by the American Diabetes Association as chairman of a committee for the establishment of a national "Diabetes Week," December 6 to 12, 1948. The function of this committee is to consider ways and means of securing the earlier diagnosis and treatment of approximately a million patients in the United States and Canada who at present are unknown and therefore untreated.

Dr. John F. Conlin, director of medical information and education, discussed with the Committee on Public Relations the desirability of a state-wide health meeting to be held early in 1949. It is the intention of this meeting to bring together approximately one thousand delegates from the various consumers and suppliers of medical service to discuss matters pertaining to a future program for health and medical care within this Commonwealth.

Numerous agencies and groups, such as the parent-teachers' associations, the dental profession, service clubs and the Massachusetts Hospital Association, have already been informally approached and have expressed an interest and a willingness to co-operate in such a venture. Dr. Conlin stressed the fact that such a meeting would consist in a panel and section discussion of matters pertaining to medicine and health. It is planned to hold brief meetings in major population centers of the state, following the Boston meeting, in order to disseminate material from this initial Boston meeting in the widest possible manner. It was therefore unanimously approved by the Committee on Public Relations that such a state-wide health meeting be conducted and that the Council be requested to appropriate the sum of \$500 as the Society's contribution toward this important activity.

Dr. Conlin then gave a very informative talk with reference to the work of his office. He stated that much progress had been made in the formation of the Woman's Auxiliary to the Massachusetts Medical Society. Many projects were under consideration for the continuation and extension of the work of this organization, such as legislation leading to the obtaining of animals from public pounds for the purpose of teaching and medical research, informational programs leading to better understanding of matters of medical economics and so-called, "socialized medicine", the gathering of medical journals and certain medical supplies for needy overseas areas, the matter of a long-range plan for a health museum, and the planning of activities leading to better relations with medical students, interns, and residents, and in particular with their wives.

Report was made of the general value of the "fact sheet" published by the Massachusetts State Nurses' Association, for which the Society contributed \$50.

The matter of exclusive rights of the Massachusetts Medical Society to the radio program, "Doctor's Orders," was discussed. Up to the present there has been no charge by the broadcasting stations with reference to this program. From now on, however, there would be an estimated charge of \$140 for an initial twenty-six-week period, with renewal at \$170 for the next thirteen weeks, and \$210 for an additional thirteen weeks. Some dissatisfaction was expressed by the members of the Committee with reference to the recorded dramatizations, and particularly with the musical backgrounds. The particular value of this program was held to be derived from the interviews with local physicians, "preferably on a live basis." No action was taken with reference to the matter of "Doctor's Orders" as a public-relations instrument.

Increased use of the work of various committees of the Society for bringing its activities before the public was also discussed. It was emphasized that certain committees, such as those on cancer, industrial health, school health and mental health, in addition to serving as reference committees, could well report from time to time on matters of general and current interest in their various fields. Such reports to the Council could well furnish the basis of periodic news releases and so keep the Society and its interest in medical progress and public health before the public eye through an interested and co-operative press.

Dr. Conlin pointed out the importance of making every effort to interest medical students, interns and residents in the desirability and importance of membership in the Medical Society. It was felt that the present flat fee for member-

ship in the Massachusetts Medical Society was a barrier to many eligible physicians during their early years of formal postgraduate training. The policy of an ascending scale of membership dues to ease the financial burden of these physicians might be a desirable policy to be initiated by the Society.

The Committee on Public Relations recorded itself as endorsing such an ascending scale of membership dues and urges that this matter be referred to a proper committee for study.

As further evidence of the interest of the Massachusetts Medical Society in this select group of students now in our approved medical schools in the Commonwealth, the matter of granting some sort of annual award to a fourth-year student in each of our three medical schools, presumably in the course of the annual meeting of the Society, was discussed. It was brought out that such an award would not necessarily be based entirely on scholastic attainment or on "likelihood to succeed," but would represent an attempt to single out certain persons as exemplifying intangible qualities that serve to designate him as "the good physician."

It was moved and unanimously approved that the Committee on Public Relations recommend to the Council the appointment of a committee to determine the nature of such an award and the proper means of selection of the recipients of this award after due consultation with the deans and faculties of the medical schools.

Dr Conlin furthermore urged that the members of the Public Relations Committee use the Society headquarters as a clearing house and central source of information. He urged that newsbreaks on matters detrimental to good medicine be reported promptly to Society headquarters. He furthermore suggested that reports of radio programs, forums and other special events within the districts are matters of public relations, and such information should be sent to him as Director of Medical Information and Education.

A major defect that continues is the absence of a qualified and co-ordinated speaker's bureau. Fellows of the Society, capable and willing to address various groups are requested to communicate with their district public-relations councilors. Demand for such speakers is increasing, and at times it is impossible to comply with all requests. Future months will see a marked increase in the demands for qualified speakers. Recently, there were received requests from the Massachusetts Department of Public Health and from a considerable number of organizations to furnish speakers for various programs. Such activities are nearly always without monetary compensation and represent a major contribution to public service and to better mutual understanding within the community.

DANIEL B REARDON, *Chairman*  
HAROLD R KURTH, *Secretary*

## APPENDIX NO 10

### REPORT OF THE COMMITTEE ON PUBLIC HEALTH

At the first meeting of the Committee on Public Health held June 5, 1948, the following members were present: Drs Roy Ward (chairman), Conrad Wesselhoeft, Warren R Sisson and John J Poutas. Dr L Jackson Smith of Springfield was unable to be present. Also present were Dr Arthur W Allen, president-elect, and Dr H Quimby Gallupe, secretary of the Massachusetts Medical Society.

The first item of business was the election of a secretary. Dr John J Poutas was elected secretary for the third consecutive year.

At the request of Dr Ward, the secretary then read to the Committee a letter from Dr Walter E Barton, dated October 29, 1947. Dr Barton submitted this letter as chairman of the subcommittee on mental health, pointing out that in August, 1948, a congress will be held in England dealing with mental-health problems. This International Medical Congress has asked that medical societies sponsor regional meetings in the interest of the prevention of sexual psychopathy. It was pointed out that on July 16, 1947, the Massachusetts Medical Society offered to co-operate in any way possible with the Massachusetts Recess Commission, which studied this problem. It was Dr Barton's request that the regional meetings desired be sponsored by the Society rather than through the specialists' channels of the Massachusetts Psychiatric Association. It is the opinion of the subcom-

mittee on mental health that this project is too cumbersome to be included in the annual meeting of the Society. A discussion of Dr Barton's letter elicited the approval of the Committee, and Dr Wesselhoeft made a motion that the chairman of the subcommittee, Dr Walter E Barton, communicate with Dr W Richard Ohler, chairman of the Committee on Postgraduate Medical Education, and develop with him the inclusion of this subject in the postgraduate program, being mindful of the fact that this was in effect a pediatric problem more effectively covered by a panel of speakers covering all age groups rather than by one single speaker.

The next item on the agenda was a report by Dr Sisson of his analysis of the data submitted by the various medical schools in New England, outlining the educational program with respect to preventive medicine, including accident prevention. Dr Sisson reported that in his opinion this problem is being very effectively attacked by the various life-insurance companies. He was of the opinion that medical schools should enlarge the scope of their program to include more adult lay education. He recommended to the committee that no particular action be taken at this time other than to communicate our interest in this matter to the Director of Medical Information and Education. His recommendation was approved by the Committee.

The secretary then read to the Committee two communications from Dr Lewis C Robbins of the Heart Demonstration Program being conducted in the City of Newton by the United States Public Health Service. This program, together with an epidemiologic study of heart disease being conducted by the Public Health Service in the Town of Framingham, was endorsed in principle by this committee in March, 1948. As a result of this endorsement, the Council approved these studies. Monthly reports of April and May, 1948, of the program as conducted in Newton were read. It was agreed by the Committee that the Public Health Service physicians conducting the program in the City of Newton and in the Town of Framingham should be invited before the next meeting of the Committee on Public Health to give a report of progress. It was also recommended by the Committee that Dr Howard B Sprague be invited to the meeting of the Council to answer any questions about these programs.

The next matter on the agenda was a reading of a letter from Mr Parker Wheatley, of the Lowell Institute Co-operative Broadcast Council. In this letter Mr Wheatley outlined a radio program with health topics, particularly infant care. This program is endorsed by all of the Boston universities and colleges and is indirectly supervised by the deans of the three Boston medical schools. In his letter, Mr Wheatley asked for the committee's consideration of his educational program and, if possible, its endorsement.

It was decided by the Committee that we communicate our interest and endorsement to the Director of Medical Information and Education with the recommendation that he further study the matter of Society co-operation in this regard. It was recommended that Dr Conlin get in touch with Mr John E Farrell, executive secretary of the Rhode Island State Medical Society, relative to this program in the interest of avoiding conflict with a similar program sponsored by the Council of New England Medical Societies.

The next matter for discussion was a recent editorial in the *New England Journal of Medicine* relative to the advisability of active immunization against tetanus. After considerable discussion as to the advisability of general community active immunization against tetanus the following resolution was adopted: that the Committee is interested in the proper and judicious use of tetanus toxoid in active immunization and was pleased to note that it was the subject of editorial comment in the *New England Journal of Medicine*.

Next on the agenda was a reading of a letter from Mr Gates, of the New England Heart Association. This letter outlined the proposed program of that association whereby a certain amount of money would be available for the provision of penicillin in cases of subacute bacterial endocarditis. This program has the approval of Drs Edward F Bland, Samuel A Levine and Maxwell Finland.

No test for indigency will be carried out. A statement from the patient's physician to the effect that treatment would be a financial hardship and that funds for penicillin are not available from other sources is expected to suffice.

WHEREAS, To permit such graduates to become eligible for examination in Massachusetts would lower the high standards of medical licensure already established in Massachusetts by the present medical practice act, therefore be it

RESOLVED, That the Council of the Massachusetts Medical Society protest against the present policy of the Veterans Administration in this respect, and be it further

RESOLVED, That a copy of this resolution be sent to the Veterans Administration and all other interested parties and organizations

HARVEY A. KELLY, *Chairman*

## APPENDIX NO 9

### REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The meeting of the Committee on Public Relations was held at the Harvard Club at 6:00 p.m. on August 4, 1948. In addition to the representatives of thirteen district societies there were present President Daniel B. Reardon, chairman, Dr. Arthur W. Allen, president-elect, Dr. H. Quimby Gallupe, secretary of the Society, Dr. John F. Conlin, director of medical information and education, and Mr. Robert St. B. Boyd, executive secretary.

The report of the Secretary as printed in the advance notice of the meeting of the Council on May 24, 1948, was accepted.

President Reardon read a letter from Dr. Howard F. Root, Suffolk District, in which Dr. Root suggested to the Committee on Public Relations that the Massachusetts Medical Society initiate a "Health Week Program" in November of 1949. This "Health Week Program" would consist essentially of a public exhibit of the most recent advances in medicine, emphasizing preventive medicine as well as treatment. Allied organizations such as the Massachusetts Department of Public Health, the State Nurses' Association, the State Hospital Association and particularly the Woman's Auxiliary of the Massachusetts Medical Society would be invited to take an active part in such a program.

Dr. Bernard Appel, Essex South, stated that the City of Lynn has had such a health exhibit annually for the past fifteen to eighteen years. It was his opinion that there was much public interest in this type of medical educational program. Many of the civic organizations such as the service clubs and parent-teachers' associations lent active support in the conduct of the Lynn program.

Because of the amount of preparation that would be necessary in the initiation and creation of such a health exhibit, it was felt that a program of this type would require at least a year of preparation, hence the date, November, 1949.

A motion was made by Dr. Henry A. Robinson, Norfolk South, "that the Committee on Public Relations recommend to the Council that it initiate such a public-health exhibit" and "that the president of the Massachusetts Medical Society be empowered to appoint a committee consisting of a representative from each district to initiate such a program immediately."

The motion was unanimously carried.

Dr. Howard F. Root, Suffolk, called the attention of the Committee to the problem of how to meet the needs of medical students in the future when the G. I. Bill of Rights ceases to function. It is evident that within a measurable period many students in medical schools who are at present receiving support from the United States Government will be in need of some financial assistance in order to complete their medical education. The Committee on Public Relations is well aware of the fact that the establishment of a loan fund for medical students by the Massachusetts Medical Society represents a change in fundamental policies, but nevertheless considers it to be good public relations. This committee therefore endorsed the following resolution: "That the ques-

tion of the establishment of a student loan fund be referred to the Council for its serious consideration."

As a matter of information, President Reardon reported to the Committee that Dr. Howard F. Root has been appointed by the American Diabetes Association as chairman of a committee for the establishment of a national "Diabetes Week," December 6 to 12, 1948. The function of this committee is to consider ways and means of securing the earlier diagnosis and treatment of approximately a million patients in the United States and Canada who at present are unknown and therefore untreated.

Dr. John F. Conlin, director of medical information and education, discussed with the Committee on Public Relations the desirability of a state-wide health meeting to be held early in 1949. It is the intention of this meeting to bring together approximately one thousand delegates from the various consumers and suppliers of medical service to discuss matters pertaining to a future program for health and medical care within this Commonwealth.

Numerous agencies and groups, such as the parent-teachers' associations, the dental profession, service clubs and the Massachusetts Hospital Association, have already been in formally approached and have expressed an interest and a willingness to co-operate in such a venture. Dr. Conlin stressed the fact that such a meeting would consist in a panel and section discussion of matters pertaining to medicine and health. It is planned to hold brief meetings in major population centers of the state, following the Boston meeting, in order to disseminate material from this initial Boston meeting in the widest possible manner. It was therefore unanimously approved by the Committee on Public Relations that such a state-wide health meeting be conducted and that the Council be requested to appropriate the sum of \$500 as the Society's contribution toward this important activity.

Dr. Conlin then gave a very informative talk with reference to the work of his office. He stated that much progress had been made in the formation of the Woman's Auxiliary to the Massachusetts Medical Society. Many projects were under consideration for the continuation and extension of the work of this organization, such as legislation leading to the obtaining of animals from public pounds for the purpose of teaching and medical research, informational programs leading to better understanding of matters of medical economics and so-called, "socialized medicine", the gathering of medical journals and certain medical supplies for needy overseas areas, the matter of a long-range plan for a health museum, and the planning of activities leading to better relations with medical students, interns, and residents, and in particular with their wives.

Report was made of the general value of the "fact sheet" published by the Massachusetts State Nurses' Association, for which the Society contributed \$50.

The matter of exclusive rights of the Massachusetts Medical Society to the radio program, "Doctor's Orders," was discussed. Up to the present there has been no charge by the broadcasting stations with reference to this program. From now on, however, there would be an estimated charge of \$140 for an initial twenty-six-week period, with renewal at \$170 for the next thirteen weeks, and \$210 for an additional thirteen weeks. Some dissatisfaction was expressed by the members of the Committee with reference to the recorded dramatizations, and particularly with the musical backgrounds. The particular value of this program was held to be derived from the interviews with local physicians, "preferably on a live basis." No action was taken with reference to the matter of "Doctor's Orders" as a public-relations instrument.

Increased use of the work of various committees of the Society for bringing its activities before the public was also discussed. It was emphasized that certain committees, such as those on cancer, industrial health, school health and mental health, in addition to serving as reference committees, could well report from time to time on matters of general and current interest in their various fields. Such reports to the Council could well furnish the basis of periodic news releases and so keep the Society and its interest in medical progress and public health before the public eye through an interested and co-operative press.

Dr. Conlin pointed out the importance of making every effort to interest medical students, interns and residents in the desirability and importance of membership in the Medical Society. It was felt that the present flat fee for member-

not been able to adhere completely to the suggestions of the American Heart Association, owing to lack of funds. These clinics can be helped either by the purchase of equipment, by furnishing of service for indigent patients or by assistance in providing personnel. Approval by the American Heart Association shall be the goal of the cardiac-clinic subsidization. Funds will not be available to clinics unless such funds will permit the clinic to meet the standards of the Association. Available funds will be furnished cardiac clinics approved by the technical committee.

**Selection of a demonstration area.** The northeastern district, consisting of 10 cities and 35 towns will be chosen for a demonstration area. There are 18 hospitals in the 10 cities and 1 in each of 7 towns. The total bed capacity is 2008. This area had a total population of about 600,000 in 1940 with 240,000 persons over the age of forty. The distribution of the population in this district ranges from a town of about 800 to a city of approximately 100,000. The establishment of relations with the local and state heart-association officials will be made at the earliest opportunity. The Massachusetts Department of Public Health will approve the association of program plans and discuss the most effective methods of co-operation. Goals will be established as a part of the program for co-operative projects.

**Survey of the facilities in the demonstration area.** The facilities for diagnosis, treatment and care of cardiac disease should be ascertained and made use of. Information regarding the presence of heart disease and various environmental factors regarding living conditions that may be detrimental to the well-being of the patient will be ascertained by spot surveys similar to those conducted in cancer.

**Establishment of a demonstration heart registry.** In the demonstration area a heart registry will be started. This registry will be of great assistance to the profession. It will elicit facts on incidence and permit evaluation studies of the most worthwhile parts of the program, the degree to which patients follow the recommendations of the professions and many epidemiologic facts. It will enable physicians, who so desire, to make use of the part of the program discussed below under public health services for cardiac patients.

**Inauguration of a state-wide educational program in heart diseases for the laity.** After the indoctrination of the medical profession in the basic principles of control is well underway a state-wide educational program for the laity should be inaugurated. Preparation for this activity could begin at an earlier date. The scope of education in heart diseases shall be determined by the Advisory Committee and then put into concrete form by the Department. Use will be made of all the educational mediums, such as lectures, radio pamphlets, charts, exhibits, newspaper articles and movies.

**Development and extension of public-health services for cardiac patients in local health departments.** The local health organization in the demonstration area should furnish such follow-up and other services for cardiac patients as are consistent with the disease and requested by the attending physician. Such a program will be designed to increase the effectiveness of the practicing physician through health education and making available such services as rehabilitation, nutrition, nursing and epidemiology. Co-operation with the local heart association will increase the effectiveness of the program.

**Personnel training.** The contemplated expansion of the heart program will necessitate more personnel trained in public health and heart disease. A personnel-training program will be started on a small scale. This program will be designed to give public-health training to physicians, health educators, nurses and other public-health workers commensurate with the needs of the program.

**Statistical studies.** Statistical studies to measure the effectiveness of the program will be frequently done as well as other statistical studies on heart diseases similar to those found useful in cancer and diabetes control.

Throughout the program every effort will be made to avoid duplication of effort and to furnish the utmost co-operation among the various groups involved. The Heart Disease Epidemiology Study, the Heart Demonstration Program, Rheumatic Disease Program and Division of Hospitals will co-ordinate their efforts to accomplish the greatest results. Early liaison will be established with the New England Heart Association and local affiliates.

## FEDERAL BUDGET FOR HEART PROGRAM

*Breakdown of Costs*

01	Assistant director	\$5,400 00	
	Public-health social work supervisor	2,880 00	
	Public-health nursing (2) supervisors	5,760 00	
	Assistant biometrician	2,460 00	
	Supervisor of public-health education	2,800 00	
	Senior statistical clerks (2)	4 520 00	
	Senior clerk and stenographer	1 980 00	\$25,600 00
02			
03	Consultant	\$1,500 00	1 500 00
07	Aid to existing heart clinics	15 000 00	15 000 00
10	Travel and automobile expense	1,500 00	1,500 00
11	Advertising and printing	1 000 00	1 000 00
13	Personnel training	6,000 00	
	Medical education	10,000 00	
	Nonprofessional education	1,000 00	17 000 00
14	Office expenses	1,000 00	1 000 00
15	Automobiles (2)	3,300 00	
	Office equipment	1 200 00	4,500 00
16	Garage rental	360 00	
	Other rent	3,000 00	3,360 00
	Total budgeted		\$70 460 00

## GENERAL AND ALLIED SPECIAL HOSPITALS IN NORTHEASTERN HEALTH DISTRICT

City or Town	Name of Hospital	No. of Beds
Amesbury	Amesbury	35
Beverly	Beverly	166
Danvers	Hunt Memorial	20
Gloucester	Addison Gilbert	71
Haverhill	Benson	34
	Hale Municipal	161
Ipswich	Benjamin Cable	19
Lawrence	Bessie Burke	125
	Clover Hill	55
	Lawrence General	183

The Committee approved of this program of the New England Heart Association and recommended that when agreeable to the New England Heart Association it might be the subject of editorial comment in the *New England Journal of Medicine*.

Dr Howard F Root appeared before the Committee and outlined the responsibility of the medical profession in the earlier discovery and treatment of diabetes mellitus. He read to the Committee a proposed resolution of Dr Phippen, as follows:

WHEREAS, The medical profession has always recognized its obligation for the discovery, treatment, and prevention of diabetes mellitus, and

WHEREAS, The number of latent and undiscovered diabetic patients in the United States, according to surveys, is much larger than had been supposed, and is estimated to be about one million persons, and

WHEREAS, There exists also a large number of patients whose diabetes is neglected and who are therefore under ineffective or no treatment, and

WHEREAS, The American Diabetes Association, Incorporated, whose membership consists of more than a thousand doctors interested in diabetes, has appointed a committee to formulate plans for a national "Diabetes Week," December 6 to 12, 1948, and

WHEREAS, The purpose of this effort is to assist doctors and local committees in effectively carrying out continuing plans for discovering the unknown diabetics and guiding them to their physicians, and for spreading widely to the public, information about diabetes, and

WHEREAS, This is to be a doctors' project, of the profession, by the profession, and for the public, and

WHEREAS, To achieve the aims of "Diabetes Week," the American Diabetes Association seeks to enlist the formal support and active co-operation of the medical profession through the American Medical Association and its constituent and component societies, therefore be it

RESOLVED, That the Council of the Massachusetts Medical Society heartily endorse the efforts of the American Diabetes Association in behalf of the undiscovered and untreated diabetic and approve of the plans for a "Diabetes Week" from December 6 to 12, 1948.

Furthermore, be it resolved that the delegates from the Massachusetts Medical Society to the House of Delegates of the American Medical Association be instructed to present this resolution to the House and recommend that the trustees of the American Medical Association and all state, county and other medical societies co-operate and participate in the effort to find as many as possible of the unknown diabetics in order to bring them under medical treatment.

The Committee approved Dr Phippen's resolution and a motion was made and adopted that we recommend to the president of the Massachusetts Medical Society that a committee be appointed to expedite the Massachusetts "Diabetes Week" program from December 6 to 12, 1948, that this committee be empowered to act, and that its efforts be co-ordinated with those of Dr Ohler's Committee on Post-graduate Education. It was also moved and adopted that the Council take necessary action relative to the final paragraph of Dr Phippen's resolution.

The final item of business was a discussion of the need for active interest of the medical profession in the problem of geriatrics. It was recommended that Dr Ward inform Dr Robert Monroe of the Committee's interest and desire to be of assistance.

ROY J. WARD, *Chairman*  
JOHN J. POUTAS, *Secretary*  
WARREN R. SISSON  
L. JACKSON SMITH  
CONRAD WESSELHOEFT

#### SUPPLEMENTARY REPORT OF COMMITTEE ON PUBLIC HEALTH

During the last session of Congress the sum of \$500,000 was appropriated to make effective the National Heart Act. This sum is to be distributed to a group of states yet to be selected. It is the desire of the Department of Public Health that Massachusetts be included in this group of states, and that a portion of this fund be allotted to them to further

their study of heart disease already initiated here. The Department has drawn up the following program for the development of this study. This program has the approval of the Committee on Public Health.

A National Heart Institute has been established by Congress this year. As a part of this over-all heart program, the Massachusetts Department of Public Health is hoping to inaugurate a heart demonstration program in this state. It is concerned with attempting to meet the growing problem of heart disease, which, according to Dr Paul D White, is the greatest public-health problem of the day. The proposed program recognizes that the physician in private practice is the key man in the control of heart disease. This program is an attempt to assist the physician, aid him where possible and increase his effectiveness in the community without establishing new services.

*Appointment of advisory committees.* Two committees shall be appointed: one shall be a technical advisory committee composed of specialists in heart disease. This committee shall discuss matters of policy and, by a fine screening, review the important policy matters. The second committee shall be called the operating committee. This committee shall be composed of representatives of the several agencies and interests in heart disease in the local area. It shall be concerned with making a continuous study of the operations of the demonstration program, as well as other heart activities of the area. It shall make recommendations to official and other agencies concerning the better operation of the program.

*Inauguration of an educational program for physicians.* Success in this program depends on participation by physicians. Pessimism on the part of many general practitioners, together with lack of knowledge on the part of some, is an obstacle to heart-disease control. The Department of Public Health will inaugurate, in co-operation with the professional medical groups, a state-wide program of physician education. As part of the Massachusetts Medical Society's graduate courses, sessions on heart diseases, better to train physicians for general practice, will be arranged by the Department with the assistance of the New England Heart Association. No attempt will be made to develop cardiologists. The purpose will be to develop an awareness on the part of physicians concerning the cardiac problem, the difficulties of diagnosis of certain types and the limitations within which the general practitioner can safely operate without harming the patient. No certificate will be given by the Department for completion of the course. The demonstration of heart sounds by the use of a multiple stethoscope amplifier will be provided physicians. Preliminary discussions have been held with Society officials, and tentative plans made. Physicians not only will receive information concerning the clinical aspects of heart disease and the sociologic and psychologic aspects, but also will be constantly informed of the progress of the heart program. Methods of providing the physicians with important recent literature on heart disease will be one of the prime functions of the technical advisory committee. Whether this be in the form of a lending library in co-operation with the Boston Medical Library, the preparation and distribution to all physicians of a heart manual similar in style to the cancer manual or some other medium will be decided by the Committee. Approximately a quarter of the physicians in Massachusetts are not members of the Society. They are graduates of substandard schools. This group constitutes the greatest need in physician education.

*Inauguration of an educational program for nonmedical health personnel.* The nurses, social workers, biometricians, educators and other health-department personnel, together with lay members and employees of local boards of health who may be assigned to a heart program, should have an adequate knowledge of the public-health aspects of heart disease. Courses should be planned to meet this need, and furnished to key members of the various public-health professions. The instruction should begin with the health workers in the demonstration area and expand as rapidly as possible. Eventually, all members of these professions who will engage in heart-control projects must be oriented.

*Development of facilities of existing clinics.* In Massachusetts there are 19 hospitals with heart clinics meeting regularly, and 6 additional ones by appointment, which follow to a greater or lesser extent the procedures outlined by the American Heart Association. Some of these clinics have

not been able to adhere completely to the suggestions of the American Heart Association, owing to lack of funds. These clinics can be helped either by the purchase of equipment, by furnishing of service for indigent patients, or by assistance in providing personnel. Approval by the American Heart Association shall be the goal of the cardiac-clinic subsidization. Funds will not be available to clinics unless such funds will permit the clinic to meet the standards of the Association. Available funds will be furnished cardiac clinics approved by the technical committee.

**Selection of a demonstration area.** The northeastern district, consisting of 10 cities and 55 towns, will be chosen for a demonstration area. There are 18 hospitals in the 10 cities, and 1 in each of 7 towns. The total bed capacity is 2008. This area had a total population of about 600,000 in 1940, with 240,000 persons over the age of forty. The distribution of the population in this district ranges from a town of about 800 to a city of approximately 100,000. The establishment of relations with the local and state heart-association officials will be made at the earliest opportunity. The Massachusetts Department of Public Health will appraise the association of program plans and discuss the most effective methods of co-operation. Goals will be established as a part of the program for co-operative projects.

**Survey of the facilities in the demonstration area.** The facilities for diagnosis, treatment and care of cardiac disease should be ascertained and made use of. Information regarding the presence of heart disease and various environmental factors regarding living conditions that may be detrimental to the well-being of the patient will be ascertained by spot surveys similar to those conducted in cancer.

**Establishment of a demonstration heart registry.** In the demonstration area a heart registry will be started. This registry will be of great assistance to the profession. It will elicit facts on incidence and permit evaluation studies of the most worthwhile parts of the program, the degree to which patients follow the recommendations of the professions and many epidemiologic facts. It will enable physicians, who so desire, to make use of the part of the program discussed below under public health services for cardiac patients.

**Inauguration of a state-wide educational program in heart diseases for the laity.** After the indoctrination of the medical profession in the basic principles of control is well underway, a state-wide educational program for the laity should be inaugurated. Preparation for this activity could begin at an earlier date. The scope of education in heart diseases shall be determined by the Advisory Committee and then put into concrete form by the Department. Use will be made of all the educational mediums, such as lectures, radio, pamphlets, charts, exhibits, newspaper articles and movies.

**Development and extension of public-health services for cardiac patients in local health departments.** The local health organization in the demonstration area should furnish such follow-up and other services for cardiac patients as are consistent with the disease and requested by the attending physician. Such a program will be designed to increase the effectiveness of the practicing physician, through health education, and making available such services as rehabilitation, nutrition, nursing and epidemiology. Co-operation with the local heart association will increase the effectiveness of the program.

**Personnel training.** The contemplated expansion of the heart program will necessitate more personnel trained in public health and heart disease. A personnel-training program will be started on a small scale. This program will be designed to give public-health training to physicians, health educators, nurses and other public-health workers commensurate with the needs of the program.

**Statistical studies.** Statistical studies to measure the effectiveness of the program will be frequently done, as well as other statistical studies on heart diseases similar to those found useful in cancer and diabetes control.

Throughout the program every effort will be made to avoid duplication of effort and to furnish the utmost co-operation among the various groups involved. The Heart Disease Epidemiology Study, the Heart Demonstration Program, Rheumatic Disease Program and Division of Hospitals will co-ordinate their efforts to accomplish the greatest results. Early liaison will be established with the New England Heart Association and local affiliates.

## APPENDIX NO 11

## REPORT OF THE COMMITTEE ON BENEVOLENCE

This committee was appointed to implement the suggestion that the Society give thought and take action in regard to aid for physicians who are incapacitated through no fault of their own. It has also been suggested that in certain cases we might assist widows and orphans of physicians.

These functions are not new among doctors in Massachusetts. They have been performed for nearly a hundred years by the Massachusetts Medical Benevolent Society. Because this organization was especially designed for these purposes your committee decided at its first meeting that it would be undesirable to duplicate such activities. Instead, it is hoped that we may actively co-operate with the Massachusetts Medical Benevolent Society and together with it render a single amplified service.

Your committee believes that this could be accomplished if a new standing committee to be known as the Committee on Benevolence were first established. This committee would then represent the Council and could deal with the Benevolent Society in the following manner:

The Committee on Benevolence would ask the Committee on Finance and the Council for an annual budget of not more than \$10,000. The Benevolent Society would make an annual estimate of its needs as applied to Massachusetts Medical Society members. The Committee on Benevolence would then pay the Benevolent Society the amount estimated, within the annual budgetary limit of \$10,000. All applicants would apply to the Benevolent Society, and the dispensing of benevolence would be entirely in the hands of this group.

At the end of each year, any money paid to the Benevolent Society by the Benevolent Committee, but not used, would stand at the credit of the Committee on the Benevolent Society's books and would be applied to the following year. The amount of such credit would be shown in a statement made to the Committee by the Benevolent Society on or before December 31 of each year. If, on the other hand, the needs were to rise above the Benevolent Society's estimate during the year, the Committee on Benevolence might authorize further payments to the Benevolent Society up to the amount of the annual budget.

If the actual needs did not absorb the annual budget—that is, if they were less than \$10,000—the balance would be earmarked in a Committee on Benevolence account, to be invested by the Treasurer in liquid securities, which, with their interest, would provide a Benevolent Fund. This Benevolent Fund could be drawn upon at the discretion of the Committee on Benevolence if in any given year extraordinary demands for relief created a need above and beyond the budget allotment for that particular year.

For example, the Benevolent Society estimated a need of \$8000, this amount would be given to them. If they used but \$7000, a balance of \$1000 would remain on their books to the credit of the Benevolent Committee, and the next year's estimate would be correspondingly reduced. If the Benevolent Society found that it was going to need more than the \$8000 estimated, the needed amount could be advanced by the Benevolent Committee up to, but not

beyond, the \$10,000 originally budgeted. If the Benevolent Society used just the \$8000 estimated, the remaining \$2000 or whatever was left unpaid from the annual budget for any given year would be invested in the Benevolent Fund and thus held in reserve for future emergency.

Your committee feels that this proposal will provide a flexible working arrangement and will at the same time permit the development of a permanent fund for the future. For these reasons, it recommends that this proposal be adopted.

If this proposal is adopted your committee further recommends that a temporary committee on benevolence be appointed to operate until such time as the by-laws may be amended to authorize a permanent arrangement.

## APPENDIX NO 12

## REPORT OF DELEGATES TO HOUSE OF DELEGATES OF AMERICAN MEDICAL ASSOCIATION

The House of Delegates met in Chicago June 21 to 24, inclusive. All members of the Massachusetts delegation or their alternates attended. The distinguished service award was given to Dr. Isaac A. Abt, of Chicago, at the first session. The Judicial Council presented a very careful revision of the Code of Ethics that was adopted unanimously. A special committee on the constitution and by-laws, which has been working for two years, presented a revision, which was also adopted after considerable discussion. These actions were time consuming but necessary. Several distinguished guests addressed the House—Admiral Swanson, surgeon general of the Navy, the president of the British Medical Association and General Hawley, co-ordinator of the Blue Cross and Blue Shield plans.

Component societies were urged to appoint their delegates to the House before January 1 so that the Speaker can appoint reference committees at least a month before the meeting of the House. Our society should take cognizance of this rule, since otherwise delegates will not be given reference-committee appointments.

The House voted to change the method of selecting candidates for the distinguished service award for general practitioners. Hereafter each county or district society will be asked to nominate one of its members, if it sees fit, to the state society. The state society will then select one of these nominations to be sent to the American Medical Association headquarters. Three of these will be selected by the Trustees to be voted upon by the House at its interim session.

The House went on record in favor of one year's rotating internship for every graduate of medicine and requested the Council on Medical Education and Hospitals to activate this procedure.

It was also announced that the Council on Medical Education and Hospitals was undertaking a survey and revision of medical education with special reference to the curriculum of medical schools.

Also contemplated is a foundation for the solicitation and distribution of funds to help finance medical schools and medical education.

The Council on National Emergency Medical Services suggested certain basic principles to guide the American Medical Association under the threat of national emergency, which were unanimously adopted. It affirmed that the services of physicians must be carefully conserved and judiciously allocated in time of war to ensure adequate medical, health and sanitary care for all Americans, whether in or out of uniform. It recommended, among other things, a single physical examination of recruits and inductees and deferment of properly selected and duly registered premedical and medical students and essential teachers. The call of medical officers to military duty should be in the following order: those educated at Government expense, those who did not serve in World War II, and those who served least in World War II. State and county societies should use every effort to induce such men to volunteer.

MASSACHUSETTS MEDICAL SOCIETY

Vol. 2:9 No 23

A resolution that received considerable publicity sought to amend the constitution of the American Medical Association so as to prohibit the exclusion of certain classes of physicians from membership in component county societies. It was pointed out that the American Medical Association has never excluded physicians on the basis of race but that the component medical society is the sole judge of whom it elects to membership provided the applicant shall meet the medical requirements for membership.

From testimony presented at several hearings concerning the American Red Cross blood bank it was evident that there has been some confusion and misunderstanding between local chapters of the Red Cross and the medical profession at local levels. The House of Delegates, recognizing the professional ability of the physicians constituting the Advisory Committee of the American Red Cross and the efforts they have made in behalf of this program, as well as the efforts of a similar committee, approved by the House of Delegates of the American Medical Association in January, 1948, felt that this intimate co-operation would be continued but that even greater effort and co-operation would be necessary in the future. It therefore recommended that the Advisory Committee be increased to nine members with definite instructions to meet at stated intervals, and to report from time to time to the House.

Resolutions pertaining to what is somewhat loosely known as the "practice of medicine by hospitals" have been introduced annually to the House of Delegates for several years. They have dealt largely with the specialties of anesthesiology, radiology and pathology. The House has repeatedly taken the position that these specialties are the practice of medicine and not hospital practice and that these departments should not be used to finance other departments of the hospital. The sore still festers. The House of Delegates has no police power to implement its decisions.

To clarify this troublesome problem the trustees of the American Medical Association appointed a committee of five under the chairmanship of Elmer Hess, of Erie, Pennsylvania. I was asked to serve on this committee. The full committee held many meetings at Chicago and heard representatives of the various specialties. The subject is so broad and has so many ramifications, and practice differs so much in different parts of the country that the committee could not reach any definite opinion to the time at its disposal. It was asked to be continued and that the Bureau of Legal Medicine and Legislation of the American Medical Association be instructed immediately to make a study of the various state laws defining the legal status of corporations attempting to practice medicine in the various states, defining in each instance the difference in the various state laws concerned with the problem. The committee will continue at work and will be glad of any suggestions or comments sent to Dr. Elmer Hess, Erie, Pennsylvania, or to me at 51 Chestnut Street, Salem, Massachusetts.

More resolutions than usual were presented, but all received meticulous hearings in the various reference committees and the reports they rendered to the House were so carefully considered and worded that they were usually adopted without lengthy debate. On the whole one must be impressed with the smoothly running machinery of the House of Delegates under the skillful guidance of the Speaker, Dr. Roy Foots, who is retiring this year after serving several years. He will be succeeded by Dr. Francis F. Borzell, of Philadelphia, who has been the vice-speaker for several terms.

WALTER G. PHIPPS

ity of existing agencies to deal with them. Trained personnel is scarce therefore, it became one of the primary purposes under the federal Mental Health Act to train more skilled workers for work in the field of psychiatry. An amount of \$1,450,000 was appropriated for use in this country to train doctors, nurses, social workers and other members of the psychiatric team. A fund of \$100,000 was established for the entire country, to be used for research fellowships and \$470,000 was set up for research. Money for training and research has been allotted by federal committees in Washington to centers of training and research throughout the country on the basis of need and the quality of supervising personnel available. It is to be regretted that Congress made a substantial cut in the amount of money originally set up to do the work.

The need for trained workers in psychiatry is tremendous. The money made available is far below the need and what could be spent to advantage. There are many excellent training centers and research institutions that could have been participating but the lack of funds which were not appropriated, made it impossible for them to co-operate. There are many excellent men applying for training in psychiatry who cannot follow the long course because of lack of funds.

A total of \$3,550,000 was appropriated in the United States for psychiatric community service. This money is allotted directly to states and federal funds are matched at the rate of \$2.00 for \$1.00. The share of Massachusetts was \$101,200 which is expended under the supervision of the Department of Mental Health.

The following projects have been carried out in the Commonwealth with the money granted:

Assistance to certain overcrowded clinics for the emotional problems of children so that more children were helped and the waiting time for such help was reduced. This resulted in better and earlier community adjustment.

Regular psychiatric advisory service to the three state training schools for delinquent children. Two of these schools are for boys, and one for girls. This service is pertinent to the study of aggression and the cause of community rehabilitation of children whose aggressive acts have exceeded the limitations of social acceptance.

Regular psychiatric advisory service to several of the more important and active courts, all of which try substantial numbers of children as well as adults. This is a humane and economical effort to reduce hospital examinations and to give advisory service to the presiding justices and their probation officers "on the spot" prior to disposition.

Supervisory service to organize and promote more fully the preparation or training program for nurses, licensed attendants and attendants. This is a fundamental need aimed to offer a fair degree of orientation to these groups from all fields of medicine and public health. It is one of the most important considerations. A central film library dealing with psychiatric subjects to assist in teaching has been established in the Department of Mental Health.

During the war, as a matter of necessity, it became important to bring into the mental hospitals certain general practitioners from the community. Their purpose was to do routine physical examinations, blood tests, conduct employee choices and give inoculations, thereby freeing the scarce resident psychiatric doctors to utilize more fully their own skills to the greater advantage of patients. These physicians became better oriented in psychiatric work, and the community reaped the benefit of this experience. This program has been greatly expanded.

Of particular importance in the long-range program has been the training, on a part-time basis, of general practitioners from the smaller communities. These doctors were assigned in four mental hospitals for training in psychiatry. There was no intention to make specialists of the family physicians but rather to help them meet demands for more information regarding incipient mental illnesses and emotional disturbances.

Assistance was given to teaching hospitals with outpatient work in psychiatry. Grants for personnel and supplies were made for the training of personnel who might later be able to operate such facilities.

Some aid was given also to local psychiatric clinics.

APPENDIX NO 13

REPORT OF THE SUBCOMMITTEE ON MENTAL HEALTH

The Committee on Mental Health met on August 12, 1948, with Drs. Barton, Taddell and Malamud and Dr. William C. Inman, invited as a consultant, present.

Your committee recommends that this report be made accessible to the members of the Society in order that they may know how federal funds are being spent in the Commonwealth to procure mental health. The demands for psychiatric help for children and for adults, both in and out of institutions, far exceeds the capacity

### State Hospitals

Our medical colleagues, in particular, and the public in general, should be aware of the plight of the state hospitals. Mental hospitals have suffered severely during recent years from a shortage of trained personnel. This shortage has been made worse by the provision of salaries that will not attract workers to the Commonwealth, since the surrounding states offer higher wages in competition. Hospitals are extremely overcrowded, making management of patients difficult. There is need for new construction. Adequate funds must be appropriated for operation.

Appropriation increases have not realistically adhered to patient-care standards and have not kept pace with the rising costs of things that must be bought.

Doctors and their patients must exert pressure on the Legislature to make adequate provision for the care of the mentally ill, the feeble-minded and the epileptic, in our state hospitals.

### Massachusetts Psychiatric Society

It was recommended that the Massachusetts Psychiatric Society (a district society of the American Psychiatric Asso-

ciation) be invited to meet jointly at the annual meeting of the Massachusetts Medical Society and to arrange a program of general interest on a psychiatric topic.

It seems highly desirable that there be less separation among specialty groups with a greater awareness of common medical problems. Instead of suggesting the creation of a new section on nervous and mental diseases that would hold special sessions at the annual meeting, it seems desirable to invite the existing state psychiatric society to convene in joint session and to provide a suitable program from which all would profit as a part of the Massachusetts Medical Society's annual scientific program.

### Education of the Public

This committee understands that the Massachusetts Medical Society has sponsored a radio series designed to educate the public on health needs. It would appear advantageous to have some of the programs devoted to the topic of mental health.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

### CASE 34491

#### PRESENTATION OF CASE

A forty-one-year-old housewife was admitted to the hospital because of multiple fractures.

Six years before entry she began to have attacks of vomiting, which were attributed to gall-bladder disease. She became pregnant and suffered from toxemia but managed to deliver a full-term infant. The baby had convulsions for three weeks after birth. Three years before entry her menses ceased and she had had hot flashes. During the same year a laparotomy was performed, with removal of a chronically inflamed gall bladder containing stones. Soon after operation she began to notice definite malaise, generalized pains, easy fatigability, irritability and attacks of chest pain, dyspnea and palpitation. She was treated by a physician with Lugol's solution without improvement. She then developed swellings of the bones of the lower limbs and some deformity and later had a spontaneous fracture of the right tibia and fibula when getting up from a chair. She was hospitalized for one month. The bones were reported to be soft—"they could not tell the difference between tissues and bones." Finally an exploration of the neck

was carried out and a tumor nodule 2.5 cm in diameter was removed from below the right lobe of the thyroid gland. This was reported as "parathyroid adenoma." She apparently had postoperative tetany, which responded to hytakerol and calcium. She improved considerably, and by the next year she was able to get about, using only a high sole to correct for the shortening of the right leg. However, she never completely regained her strength, and x-ray studies showed cysts forming in the right femur. Six months before entry another neck exploration was done, and the right lobe of the thyroid gland was removed as well as two nodules on the right side. The pathological report was "chronic interstitial thyroiditis." She did not improve, and two months later the neck was again explored, but no parathyroid tumor was found. A biopsy removed from the left side was reported as showing "epithelial hyperplasia of the parathyroid gland." The next week while still in the hospital she fractured the right femur while getting on the bedpan. The following week the mediastinum was explored, with removal of a "parathyroid adenoma showing suspicious epithelial hyperplasia." She was transferred to this hospital by plane. On the way she fractured the left femur while getting on the bedpan.

Over the past three years she had had polyuria, polydipsia and moderate constipation. The fingernails became "much stronger."

Physical examination revealed nodular tender swellings of the ribs anteriorly and flattening of the ribs posteriorly, bony thickening and irregularity of the left iliac crest and a fracture deformity of the left thigh. The right lower limb was in a plaster cast, with Steinmann pins incorporated above and below the fracture of the femur. The tongue and mucous membranes were dry, and both corneas showed abortive but definite band keratopathy and a "fish-egg" appearance to the conjunctiva.

The temperature was 99.2°F, the pulse 110, and the respirations 25. The blood pressure was 110 systolic, 82 diastolic.

The hemoglobin was 11.6 gm, and the white-cell count 8800, with 68 per cent neutrophils. The serum calcium was 15.4 mg, and the phosphorus 3.6 mg per 100 cc, the potassium 2.6 milliequiv per liter, and the alkaline phosphatase 20.6 Bodansky units. The serum nonprotein nitrogen was 37 mg per 100 cc and the carbon dioxide content was 24.4 milliequiv per liter. The serum protein, chloride and prothrombin time were normal. A twenty-four-hour specimen of urine contained 359 mg of calcium. Albuminuria was noted in only one of several urine specimens.

X-ray films of the jaws showed that the lamina dura was missing. There was marked decalcification of all visualized bones of the lower limbs, especially in the shafts of the femurs, with fractures. A plain film of the abdomen showed a staghorn renal calculus on the left side.

An operation was performed on the eighteenth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. WALTER BAUER: On the basis of the history and the laboratory findings it appears that this forty-one-year-old woman was suffering from hyperparathyroidism of at least three years' duration. The problem, as I see it, is to determine, if possible, the nature of the hyperparathyroidism. Was it due to hyperplasia of the parathyroid glands? If so, was it the result of chronic renal disease? Surely we have little evidence favoring such an interpretation. Was the hyperparathyroidism due to an excess of the parathyrotropic hormone from a parathyroid adenoma or some other condition? I think this case might be easier to interpret if we knew whether or not calcium, phosphorus and phosphatase determinations were done prior to admission to this hospital and whether or not these values were altered following removal of the "parathyroid tumors." Obviously they were not influenced for long following removal of the mediastinal parathyroid adenoma. One would like very much to know whether this first parathyroid adenoma was removed with ease or whether the surgeon, by any chance, had difficulty in resecting it. One would also like to know whether the two nodules removed from the right side of the neck at the time of the hemithyroidectomy were examined and if, by chance, they showed any evidence of parathyroid tissue. I take it that we do not have any knowledge of the nature of these nodules, nor do we know what was biopsied on the left side of the neck, later reported as showing "hyperplasia of the parathyroid gland."

DR. JOSEPH C. AUB: When was the last operation before she came in?

DR. BAUER: About four months before admission to this hospital. I would like to know whether she had a hypercalcemia, a hypophosphatemia and an increase in the alkaline phosphatase prior to the first operation. If so, did these values return to normal? They would not necessarily have to.

DR. BENJAMIN CASTLEMAN: At the time of the first operation the serum calcium was 16 mg per 100 cc. The final levels before she came here ranged from 14 to 16 mg, essentially unchanged by the operative procedures.

DR. BAUER: The patient continued to have a hypercalcemia from the time she first came under observation?

DR. CASTLEMAN: Yes.

DR. BAUER: May we see the x-ray films?

DR. STANLEY M. WYMAN: The films of the teeth show absence of the lamina dura. All the visualized bones are markedly osteoporotic, and there is some tendency to cyst formation, particularly in the shaft of the right femur. Old fractures of the right lower leg are seen in this view. There are stones in the pelvis and calyces of the right kidney. The lungs appear clear, and there is no evidence that I can see of a definite mass in the mediastinum or hilar region. It is the picture of marked bone atrophy with cyst formation and fractures.

DR. BAUER: We can say that the x-ray evidence is consistent with the diagnosis of hyperparathyroidism. From what Dr. Castleman tells us this patient apparently continued to have hypercalcemia despite the removal of the two tumors, both of which were interpreted as "parathyroid adenomas."

On reading this record I was intrigued by these quotations, "epithelial hyperplasia of the parathyroid gland" and "parathyroid adenoma, showing suspicious epithelial hyperplasia." Largely on the basis of these two statements I wondered whether, in this case, we might be dealing with a person who had cancer of the parathyroid gland. I have never seen such a case, and I have only looked up one article, namely, the one presented by Dr. Norris\* from this hospital. He reviews the literature and calls attention to 16 cases that he thinks might readily be termed cancer of the parathyroid gland. He then points out some of the difficulties in cases of this type as opposed to a lone adenoma and the cases of hyperparathyroidism due to generalized hyperplasia. In 12 cases the tumor was readily felt in the neck, and in 9 the patient was aware of its presence. It is of further interest that these nodules had been present for some time—in 1 patient as long as thirty-five years, and in others, two, three, five, eight and ten years. In 5 cases the tumor was actually observed to enlarge under observation. I inquired about the ease with which the first "adenoma of the para-

\*NORRIS, E. H. Carcinoma of parathyroid glands. *Internat. Abstr. Surg.* 86:1-21, 1948.

thyroid gland" was removed, thinking that this would be of help to me concerning the presence of cancer of a parathyroid gland. It is apparent that resection of this type of parathyroid tumor is much more difficult because of invasion of the surrounding tissue. All cases had hypercalcemia. One patient was operated on twice, and on each occasion following removal of a "tumor," the serum calcium returned to normal only to become elevated at a later date. In another case the hypercalcemia returned to normal following each of the three operations. Finally, this type of lesion can metastasize or spread locally. The metastases most commonly seen have been in the lungs, although in 1 case the liver and, in another, the bone were involved. This brings up the question whether or not a parathyroid adenoma can become malignant. From the evidence that Dr. Norris has collected it appears that such degeneration can and does take place. Certain precautions should always be taken when one is dealing with a patient of this type. The surgeon should first locate all four glands—occasionally there are more than four—before attempting removal of any tissue. It is important to have present a pathologist who is capable of diagnosing parathyroid lesions. He must tell the surgeon whether he is dealing with a lone adenoma, a hyperplastic gland or cancer of the parathyroid gland. I do not know how difficult it would be to make a diagnosis of carcinoma of the parathyroid gland on a frozen section. It is conceivable that it might be an extremely difficult job, but if any of the gross characteristics are observed, certainly it would behoove the surgeon to do as radical a resection as possible if he hoped to obtain a complete cure, that being of course the only way of curing such a lesion because it does not respond to x-ray therapy. Therefore, largely on the basis of the pathologist's referring to the presence of "epithelial hyperplasia" in two of three specimens revealing parathyroid tissue, I shall make a diagnosis of carcinoma of the parathyroid gland rather than hyperplasia of the parathyroid glands.

DR. OLIVER COPE: We were very much helped in this case by the fact that the blocks of tissue previously resected were sent along with the patient, and Dr. Castleman and Dr. Mallory obtained adequate sections and gave us a diagnosis beforehand.

#### CLINICAL DIAGNOSIS

Carcinoma of parathyroid gland

#### DR. BAUER'S DIAGNOSIS

Carcinoma of parathyroid gland

#### ANATOMICAL DIAGNOSIS

*Carcinoma of parathyroid gland*

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: We thought that this was a definite carcinoma of the parathyroid gland. It was growing with sufficient rapidity to have mitotic figures, which are unusual in adenoma, and in the second specimen, although not in the first, there was definite invasion.

DR. COPE: The initial problem presented by this patient was whether she had hyperparathyroidism or a carcinoma elsewhere with metastases invading the entire skeleton. Rapidly spreading bone metastases may mimic hyperparathyroidism from the chemical point of view, in such patients the serum calcium is elevated, and there is an excessive excretion of calcium in the urine. These findings were present in this patient, and the serum phosphorus level was normal. This last can exist in hyperparathyroidism if there is impairment of renal function. Because of the presence of carcinoma in the parathyroid adenoma already removed, hyperparathyroidism was the diagnosis, and it seemed right to attempt a radical excision of the parathyroid tissue. The operation was divided into three stages. The left side of the neck was exposed at the first stage because that was the side opposite where the large tumor had been found, and it was important if possible, to save the normal parathyroid tissue before doing a radical excision and attempting to excise all the hyperfunctioning carcinomatous tissue. A cluster of carcinomatous lymph nodes was found just above the upper end of the thoracic duct on the left—a common finding from carcinoma on the right side of the neck spreading in the lymphatics. The second operation was the exploration of the right side, it was disappointing. Only one large lymph node, swollen with carcinoma, was found. No other parathyroid tissue was encountered. We hoped that enough tissue—metastases in lymph nodes—could be found in the mediastinum to account for the continued hyperactivity. The third operation was, therefore, a mediastinal exploration, but only one small carcinomatous lymph node could I find. Removal of this small amount of carcinomatous tissue did not alter the function as judged by the absence of changes in the blood levels of calcium and phosphorus. The only assumption left to us, since there was no evidence of metastases in the lungs, was that somewhere in the bones or in the liver there must be carcinomatous tissue. That is a presumption. Dr. Lerman and Dr. Koch have been trying to inactivate the patient's parathyroid hormone by sensitizing her to the crude parathyroid extract. So far they have not been able to demonstrate inactivation. She has returned to the city from which she came, with incurable disease as far as our present abilities go.

## CASE 34492

## PRESENTATION OF CASE

A fifty-four-year-old man was admitted to the hospital because of crampy abdominal pain and diarrhea.

He had been well all his life until three years preceding admission, when he went to another hospital because of crampy pains in the lower abdomen and diarrhea without gross blood in the stool. A barium meal was said to demonstrate a duodenal ulcer, and on a dietary regime the symptoms disappeared entirely. Four weeks before entry to this hospital the same type of pain, again associated with three or four loose stools daily, returned. This time he was unable to obtain relief by changing his diet. The original episode had been accompanied by a 36-pound weight loss, which he subsequently regained, and the current attack with a 10-pound weight loss.

The family and past histories were irrelevant. The system review revealed nocturia of three or four times for the past six years without other genitourinary complaint.

Physical examination revealed a well developed, well nourished man who did not appear to be ill. The heart and lungs were normal. On deep inspiration the liver was felt two fingerbreadths below the costal margin. The prostate was enlarged to one and a half times the normal size and was smooth and symmetrical.

A urinalysis was negative. The white-cell count was 8000, and the hemoglobin was 15.5 gm (photoelectric-cell technic). Two x-ray examinations of the colon demonstrated a large, polypoid mass, measuring slightly more than 4 cm in diameter in the transverse colon (Fig 1). A colocolic intussusception, 10.1 to 12.7 cm in length, was observed, the tumor initially being in the transverse colon near the hepatic flexure, but partial reduction occurred during filling so that it took a final position near the splenic flexure. Two other rounded defects in the colon near the hepatic flexure were seen on one examination, measuring 1 and 2 cm in diameter, respectively. There was a questionable, small, polyp-like defect in the sigmoid region.

On the fourth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR CLAUDE E. WELCH: Let us see the x-ray films before starting the discussion.

DR STANLEY M. WYMAN: I think you can all see the large, somewhat lobular, but relatively smooth mass lying in the lumen of the bowel with a sleeve of intussusception running around it. Also, there is an increase in the number of folds over the region of the tumor, which is evidence of intussusception. The fluoroscopist noted that in the beginning the mass lay in the general region of the

splenic flexure, and as the barium column progressed it forced the mass proximally and, I think, in effect reduced the intussusception rather than caused it. There is no definite pattern of mucosal destruction that one can see in any of the films. All one can say is that there is a round, somewhat lobular, rather smooth, intraluminal mass, which has caused intussusception of the colon and during the examination was partially reduced. The small, questionable areas described in the protocol lie in the sigmoid. In view of the obviously poor condition of

FIGURE 1

the bowel as far as preparation is concerned, these areas cannot be taken too seriously.

DR WELCH: Dr Wyman's report and description of the x-ray film here are going to force me to change my original diagnosis as I will point out later.

It is fair to state that the first attack of pain three years before entry was not due to duodenal ulcer but was caused by the same type of disease for which the patient was admitted. This long interval suggests a benign rather than a malignant lesion. The loss of weight with subsequent complete recovery is also very suggestive of that diagnosis. There is nothing else remarkable in the history or physical findings.

About ten years ago I looked up the intussuscepting lesions of the large bowel in this hospital, stimulated by a patient of Dr Arthur W. Allen who entered with carcinoma extruding from the anus. At operation the tumor was found to arise from

the midsigmoid Dr Allen did a resection and an easy anastomosis. During a ten-year period I was able to find records of 18 intussuscepting lesions of the colon. In this group the final diagnosis was carcinoma in 13 cases, lipoma in 3, benign polyp in 1 and hemangioendothelioma in 1. Two thirds of the cases, therefore, were cancer, and the remainder of the patients had intussusception because of benign tumors.

The description of the x-ray films in the protocol at first suggested to me that the patient had benign polyps at the outset and that the polyp in the transverse colon had, after three years, developed into low-grade carcinoma. I think that is less likely now because the bowel was poorly prepared, and the suggestive polyps mentioned in the protocol are much more typical of fecal matter on the x-ray films that Dr Wyman has shown us. The surface of the mass is also quite smooth in the x-ray film. In other words, I now do not believe we are dealing with carcinoma, and the absence of other findings in the bowel inclines me definitely toward the diagnosis of lipoma since it is the most common simple benign tumor that produces intussusception in the colon.

I might state also that there are no other diagnostic features that would give help unless proctoscopy was done and polyps demonstrated. So far as stool examinations are concerned, intussusception will lead to strongly positive guaiac reactions in both benign and malignant tumors.

I will rest on the diagnosis of lipoma as the intussuscepting tumor in the transverse colon.

DR ROY E. MABREY: This is a patient of mine who had received x-ray study at another hospital three years before admission, when the diagnosis of duodenal ulcer was made. A barium enema was not done at that time. When I saw him he complained of low abdominal pain, crampy diarrhea and weight loss. Sigmoidoscopy was done, and nothing found to suggest polyposis. I then asked

for a barium enema, which revealed the findings discussed above.

I explored him, and at the time of operation I found a mass in the transverse colon. The transverse colon was redundant so that there was wide mobility of the tumor mass. On the serosal surface there were three or four grayish plaques, which I believed were carcinoma invading the serosa, and I went ahead and did a wide resection of the transverse colon with end-to-end anastomosis.

#### CLINICAL DIAGNOSIS

Carcinoma of transverse colon

#### DR WELCH'S DIAGNOSIS

Lipoma of transverse colon, with intussusception

#### ANATOMICAL DIAGNOSIS

*Submucous lipoma of transverse colon, with previous intussusception*

#### PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: The resected specimen was unusual in that the tumor, a benign lipoma, did not seem to be as big as the x-ray shadow suggests. I suppose a large part of the x-ray shadow is due to the intussusception, which was not present when we received the specimens. The tumor itself was less than 3 cm. in diameter and was only slightly elevated above the surrounding mucosa, most of the tumor being located in the submucosa. The central third of the mucosa over the tumor was ulcerated, disclosing grayish-yellow fat. This ulceration was almost certainly due to repeated attacks of intussusception that were occurring time and time again, causing gangrene of the mucosa.

Had he had any blood in the stools as far as you know?

DR MABREY: No.

## THE MASSACHUSETTS MEDICAL BENEVOLENT SOCIETY

THE Massachusetts Medical Benevolent Society, the oldest of its kind in continuous existence in the United States, was first organized at a meeting of physicians held in Boston on March 19, 1857. Its formal Article of Association reads "Whereas it sometimes happens that worthy members of the medical profession become reduced in circumstances, we, whose names are underwritten (all being residents of Massachusetts), do hereby associate ourselves as a body corporate for the relief of such, or of their families, should they need assistance." After fourteen years of activity as a voluntary association it was legally incorporated on

May 8, 1871, and has continued active to the present day. Funds are raised and invested, annual dues are levied upon the members and the sum thus accumulated, increased from time to time by gifts and legacies, has been held in trust. For ninety years the Society has annually devoted its entire income to the charitable relief of unfortunate physicians and their widows or minor children, whom circumstances have made dependent upon the pecuniary aid of others. Such has been the quiet but constant beneficence of this peculiarly characteristic medical organization.

With the growth in numbers of physicians in the Commonwealth, however, the legitimate needs of assistance have outrun the ability of the Benevolent Society to meet them. For some time, the individual members and groups within the Massachusetts Medical Society have endeavored to fill some of these needs by their own charitable activities. Obviously it is desirable that such assistance to physicians should be under a single administration, combining and correlating the work of both organizations. To this end, an arrangement has recently been formulated and adopted whereby financial relief to deserving destitute physicians in the Commonwealth shall be administered by a "Board composed of representatives of the Massachusetts Medical Society and of the Massachusetts Medical Benevolent Society." Each society retains its separate identity, but the funds of both, available for needed assistance to indigent physicians, are to be allocated and disbursed under a joint management. This seems to be an eminently just and desirable arrangement, which should meet with general approval.

It has always been an established point of honor in the profession of medicine that its members and their families should freely receive professional service in sickness. It should be felt as an equally honorable duty among physicians to see that none of their professional brethren, in old age or adversity, suffer from destitution or personal hardship.

## LOCAL HEALTH UNITS

ELSEWHERE in this issue of the *Journal* Archibald and his associates point out some critical deficiencies in the distribution of health services in Massachu-

setts To those long accustomed to regarding the Commonwealth as a leading state in point of health facilities, it is somewhat of a shock to be informed that there is no complete, statewide coverage by local health units properly governed, financed and staffed to render basic health services to all citizens. The authors present a precise enumeration of existing facilities and no less carefully define the shortcomings in quality and distribution. The most important step in the solution of the problem is stated to be enlightenment of the public concerning the need for new laws and increased facilities to keep Massachusetts abreast of progress in public health, the small communities, which cannot afford these facilities and are unwilling to relinquish autonomy to the extent of forming co-operative units to meet their joint requirements, present a particularly difficult problem. Adequately trained physicians, nurses, sanitarians and accessory personnel, in sufficient numbers to conduct a modern full-time, health organization, must be provided. And, finally, the legislature must be persuaded to appropriate sufficient funds to enable local health departments to do a creditable job.

That Massachusetts is not the only state that has failed to furnish basic health services to all citizens was revealed as long ago as September, 1947, when the National Conference on Local Health units presented a study of public-health conditions throughout the country. The six vital functions, defined at the conference and applied by Archibald et al. to Massachusetts in particular, are as follows: vital statistics, control of communicable disease, environmental sanitation, public-health laboratory services, maternity, infant and child health services, and health education so far as it is not covered in schools and colleges.<sup>1</sup> The National Health Council has also offered suggestions for improving and extending health services at the community level: joint co-operation of official and voluntary health agencies, professional societies, consumer groups and members at large to publicize existing inadequacies and promote efforts at correction.<sup>2</sup>

What may be considered the raw materials necessary for effective action are thus at hand. It remains for those most interested to exert every

effort to attain adequate distribution of health services. In view of the ever-present threat of governmental interference in the free practice of medicine, there is an ominous overtone to the statement of Archibald and his co-workers: "Until such local health units become a reality, a sound public-health program cannot be administered in an efficient, economic and competent manner." The medical and public-health professions should exert every effort to achieve the goal envisaged. Massachusetts, the cradle of many liberties, can do much to continue the free status of public-health practice: every effort to overcome the present shortcomings in health services helps to hold off the heavy, blighting hand of political pressure and dictation.

#### CURE GUARANTEED OR MONEY BACK

A DRUG manufacturing firm, nationally known, has this fall suddenly released a barrage of newspaper advertising that leaves no possible doubt as to its ethical standards in this instance. Among reputable pharmaceutical manufacturers direct advertising to the public simply is not done. So far as the acceptance of full-page weight-reduction advertisements with notarized testimonial letters is concerned, it can only be said that each newspaper will adhere to its own standards.

In this day and generation and in what might be considered good journalistic society, the flamboyant advertising direct to the public of drugs of any sort is bad taste. When the advertising matter contains testimonial letters, before-and-after-treatment photographs, money-back guarantees and certification as to safety by noted physicians (names not given), the total result is another disheartening blow to those who have worked diligently in the interests of health, the protection of the public, and the better distribution of good medical care.

The advertisement in question makes certain concessions to modern ethical considerations, showing, at least, that the advertiser is aware of

their existence. The statements are made, for instance, that the advertised product is not for glandular obesity, and that endorsement by the purchaser's physician is recommended. If the advertisers had not shown this awareness of current medical ethics, their lapse might be more readily understood.

The medical profession, as is to be expected, incurs the suspicion of self-interest when it criticizes the practice of medicine by others than its own members. Let it be admitted that an element of honest professional self-protection exists. Let it also be recognized that the physician in treating a patient assumes a responsibility that no manufacturing druggist is capable of assuming.

He assumes, in particular, the responsibility of determining to the best of his ability that the advice he offers is suited to the needs of the individual patient. He attempts, when permitted to practice his profession according to its accepted precepts, to make as accurate a diagnosis as possible before prescribing treatment. This cannot be done under the system of self-medication recommended in the advertisement under discussion and sanctioned by the newspapers that accept it.

## NEW ENGLAND HEART ASSOCIATION PENICILLIN FUND

SUBACUTE bacterial endocarditis, a complication of cardiovascular disease that has been hitherto almost universally fatal, represents another conquest of the penicillin era. In this disease particularly of the young, the mortality rate has been changed by adequate treatment with penicillin from practically 100 per cent to the vicinity of only 25 per cent.

Adequate treatment, however, consists of an enormous amount of penicillin — approximately a million units a day for a period of thirty days — a most expensive therapeutic procedure and quite beyond the resources of many patients. In this contingency and in order that no patient in New England may be deprived of suitable treatment, the New England Heart Association has set aside a special portion of the fund donated by the public last year, to provide free penicillin for those patients with subacute bacterial endocarditis who cannot otherwise procure it.

This fund is under the supervision of a special committee that has issued recommendations and established criteria as follows:

The diagnosis of subacute bacterial endocarditis is to be established by at least two positive blood cultures, although the committee may approve a request, under exceptional circumstances, when the clinical data seem adequate even with sterile blood cultures.

The treatment shall consist of a million units per twenty-four hours, in divided intramuscular doses every three hours, by continuous intramuscular drip or by slow continuous intravenous infusion unless modifications seem advisable under exceptional circumstances.

Application forms for free penicillin under the terms of this offer have been sent to all New England hospitals and are in the hands of each member of the Heart Association.

The funds for the program are limited, but, in the words of the announcement, "within its resources this association is determined that no victim of bacterial endocarditis in New England shall succumb because of a lack of adequate treatment with penicillin."

## BOOK REVIEW

*Hodgkin's Disease and Allied Disorders*. By Henry Jackson, Jr., and Fredenc Parker, Jr. Oxford Medical Publications, 4°, cloth, 177 pp., with 15 plates. New York: Oxford University Press, 1947. \$6.50.

This monograph admirably summarizes existing knowledge of a group of conditions of increasing clinical importance. The authors discuss Hodgkin's disease, reticulum-cell sarcoma, lymphocytoma and lymphoblastoma, lymphosarcoma, giant-follicle lymphoma and plasmocytoma; they advise discarding the term "endothelioma" as used by some for a member of this group.

All phases of each group, including excellent clinical descriptions, are presented. There are numerous well reproduced illustrations, particularly valuable as giving a clear idea of a varying pathological histology. Since, as the authors point out, prognosis in each patient depends very largely upon histologic appearances, biopsy study of these patients is of very great clinical import as a probable index of duration of life, some of the patients, particularly those with the histologic characteristics of Hodgkin's paraneoplasia or of giant-follicle lymphosarcoma, will live a long time in reasonable comfort, whereas others will die in a short time whatever the treatment. Incidentally, treatment for each group is thoroughly and well described.

Jackson and Parker face the often discussed problem whether Hodgkin's disease is or is not to be regarded as a neoplasm by subdividing the cases into three types: Hodgkin's paraneoplasia, Hodgkin's granuloma and Hodgkin's sarcoma. In their own words "paraneoplasia bears little or no resemblance to a true tumor", regarding granuloma type "the fact that the Reed-Sternberg cells are frequently scattered, isolated and often separated widely by cells of other types favors an inflammatory process rather than a neoplasm," whereas "on the clinical side [many features] are all more characteristic of an infectious process than of a tumor", they state that "Hodgkin's sarcoma has all the characteristics of a true neoplasm." However, they

admit that in time one type of Hodgkin's disease can change to another

The "allied disorders" included by Jackson and Parker are considered to be neoplasms either malignant or potentially malignant. Of these giant-follicle lymphoma long may behave as a benign neoplasm.

This monograph, written by a clinician and a pathologist long interested in these conditions, will prove useful to both pathologists and clinicians. The reviewer commends it to both groups of potential readers as a source of valuable information.

## NOTICES

### NEW ENGLAND DIABETES ASSOCIATION

A joint meeting of the New England Diabetes Association with the Middlesex South, Middlesex North, Norfolk, Norfolk South and Suffolk district medical societies will be held in Sanders Theater, Cambridge, on Monday, December 6, at 8 00 p m.

#### PROGRAM

Introductory remarks by the chairman, Dr W Richard Ohler

The Purpose of Diabetes Week Dr Howard F Root, chairman of the Diabetes Detection Committee, American Diabetes Association

Important Physiologic Facts Dr DeWitt Stettin, Jr, of the Public Health Research Institute, New York

Clinical Management of Diabetes (each speaker will talk for ten minutes)

Diagnosis of Diabetes Dr Joseph W Rosenthal, Norfolk District

General Management of Diabetes Dr David Hurwitz, Norfolk District

Management of Diabetes during Acute Illnesses and Surgical Operations Dr James H Townsend, Middlesex South District

Treatment of Diabetic Acidosis Dr Reed Harwood, Norfolk District

Peripheral Vascular Disease Dr E Everett O'Neil, Norfolk District

Crippling Complications of Diabetes Dr Howard F Root, Suffolk District

All the speakers will answer questions submitted either in writing beforehand or from the floor, followed by an address on the subject "After Fifty Years" by Dr Elliott P Joslin, Suffolk District

Membership in the New England Diabetes Association is open to any physician in New England. Application may be made to the Secretary, 330 Mt Auburn Street, Cambridge

### JOSEPH H PRATT DIAGNOSTIC HOSPITAL

30 Bennet Street, Boston

Lecture Hall, 9-10 a m

#### MEDICAL CONFERENCE PROGRAM

Friday, December 3 — Congenital Neurologic Cases Drs Clarence W Houghton and Nils E Svibergson

Wednesday, December 8 — Pediatric Clinicopathological Conference Drs James M Baty and H E MacMahoo

Friday, December 10 — To be announced

Tuesday, December 14 — The Relation of Opacities of the Lens to General Medicine Dr Josef Igersheimer

Friday, December 17 — Albumin in the Treatment of Hypoproteinemia Dr Sam T Gibson

Tuesday, December 21 — Journal review

Friday, December 24 — Craniopharyngioma, Ophthalmic Type, due to Pituitary Tumors (Demonstration and Discussion of Cases Operated on by Transphenoidal Methods) Dr Oscar Hirsch

On Tuesday morning, December 7, from 9 to 10 o'clock and on Wednesday mornings, December 1, 15 and 22, from 9 to 10 o'clock, Dr S J Thannhauser will give medical clinics on hospital cases. On Thursday mornings from 9 to 10 o'clock clinics will be given by Dr William Dameshek. On Friday, December 10, a therapeutic conference will be held with

round-table discussion from 2 to 4 o'clock (Dr Robert P McCombs, moderator). On Friday, December 10, Dr Merrill Sosman will conduct an x-ray conference from 4 to 6 o'clock. On Saturday mornings from 9 to 10 o'clock surgical clinics will be given by Dr C Stuart Welch. Medical Rounds are conducted each weekday except Saturday by members of the hospital staff from 12 to 1.

All conferences will be discontinued from December 24, 1948, through January 3, 1949.

All exercises are open to the medical profession.

### HARVARD MEDICAL SOCIETY AND BOSTON CITY HOSPITAL HOUSE OFFICERS' ASSOCIATION

A meeting of the Harvard Medical Society and Boston City Hospital House Officers' Association will be held in the Dowling Amphitheater of the Boston City Hospital on Tuesday, December 14, at 8 p m.

#### PROGRAM

Case Report Chronic Renal Acidosis with Osteomalacia Dr Beverly T Towery

Observations on Aureomycin Drs Harvey S Collins, E Buist Wells and Maxwell Finland

Nontuberculous Spinal Epidural Infections Dr A Price Heusner

Clinical Physiology of Vitamin B<sub>12</sub> Dr William B Castle (based on work done in collaboration with Dr Lionel Berk)

Subsequent meetings will be held on January 11, February 8, March 8, April 12 and May 10, 1949.

### NATIONAL GASTROENTEROLOGICAL ASSOCIATION 1949 AWARD CONTEST

The National Gastroenterological Association announces an annual cash prize award contest for 1949. One hundred dollars and a certificate of merit will be given for the best unpublished contribution on Gastroenterology or allied subjects. Certificates will also be awarded physicians whose contributions are deemed worthy.

Contestants residing in the United States must be members of the American Medical Association. Those residing in foreign countries must be members of a similar organization in their own country. The winning contribution will be selected by a board of impartial judges, and the award is to be made at the annual convention banquet of the Association in October, 1949.

Certificates awarded to other physicians will be mailed to them. The decision of the judges will be final. The Association reserves the exclusive right of publishing the winning contribution, and those receiving certificates of merit, in its official publication, *The Review of Gastroenterology*.

All entries should be limited to 5000 words and should be typewritten in English, prepared in manuscript form and submitted in five copies accompanied by an entry letter; they should be received not later than April 1, 1949. Entries should be addressed to the National Gastroenterological Association, 1819 Broadway, New York 23, N Y.

### APPOINTMENTS IN VETERANS ADMINISTRATION TUBERCULOSIS HOSPITALS

One hundred full-time doctors are needed by the Veterans Administration for duty in its tuberculosis hospitals.

Applicants should address their inquiries to the Chief Medical Director, Veterans Administration, Washington 25, D C.

The openings are scattered throughout the nation among Veterans Administration hospitals specializing in the treatment of tuberculous veterans and in Veterans Administration general medical and surgical hospitals operating tuberculosis departments.

The salary scale for full-time doctors in the Department of Medicine and Surgery ranges between \$4479 and \$10,305 annually for jobs now open.

During the past year, 18,222 tuberculous veterans were admitted to Veterans Administration hospitals for treatment. Discharges during the same period totaled 18,701.

(Notices concluded on page xiii)

## IT DOES HAPPEN HERE

*Severe rickets still occurs—even in sunny climates*

Vitamin D has become such an accepted practice in infant feeding that it is easy to think that rickets has been eradicated. However, even deforming rickets is still seen, as witness the above three contemporary cases from three different sections of the United States, two of them having well above the average annual sunshine hours for the country. In no case had any antiricketic been given during the first two years of life. *It is apparent that sunlight did not prevent rickets.* In other cases of rickets, cod liver oil was given inadequately (drop dosage) and even this was continued only during the winter months.

*To combat rickets simply, inexpensively, effectively—*

## OLEUM PERCOMORPHUM

This highly potent source of natural vitamins A and D, if administered regularly from the first weeks of life, will not only prevent such visible stigmata of rickets as pictured above, but also many other less apparent skeletal defects that might interfere with good health. What parent would not gladly pay for this protection? And yet the average prophylactic dose of Oleum Percomorphum costs less than one cent a day. Moreover, since the dosage of this product is measured in drops, it is easy to administer Oleum Percomorphum and babies take it willingly. Thus there is assurance that vitamin D will be administered *regularly*.

### OLEUM PERCOMORPHUM WITH OTHER FISH-LIVER OILS AND VIOSTEROL

Potency, 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10 cc and 50 cc bottles, and as capsules in bottles containing 50 and 250

## THE EFFECT OF INJURY TO THE SPINAL CORD AND CAUDA EQUINA ON THE SEXUAL POTENCY OF MEN\*

DONALD MUNRO, M D, † HERBERT W. HORNE, JR. M D ‡ AND CAPTAIN DAVID P. PAULL, M C A U S ‡

BOSTON AND FRAMINGHAM, MASSACHUSETTS

PATIENTS who are paralyzed as the result of an injury to the spinal cord or cauda equina have to face many difficult physical and psychologic problems. One of the most difficult of the psychologic ones is that which has to do with their loss of sexual ability. To discuss it at all with their doctors requires mutual understanding and confidence. Such confidence presupposes knowledge on the part of the physicians — that is knowledge of the effect of a cord injury on the various aspects of sexual and possibly married life. Unfortunately, such basic information is conspicuous by its absence. Doctors, therefore, either admit their ignorance or make up explanations and prognoses out of whole cloth.

Because of the confusion between what has been demonstrated in animals and deduced in man, all sorts of legends about the effect of spinal-cord injuries on the sexual act in man have come to be accepted. One hears, for example, that lesions of the conus will cause impotence, that transection at any level of the cord will always have the same effect, and that priapism has prognostic significance and the like. Impotence has not been distinguished from sterility, and this medical ignorance has become a matter of concern to prospective spouses. The fact appears to be that as far as we can find out, except as noted below, competent physiologic study of the effect on the sexual capacity of man of partial and transverse injuries of the spinal cord, as well as injuries of varying degree to the cauda, has not been made.

The concentration of paralytic patients with cord injuries at certain veterans' hospital centers offered a unique opportunity to study this aspect of the sterility problem in men provided that the

patients would co-operate. Such co-operation was forthcoming at Cushing Veterans Administration Hospital at Framingham, Massachusetts. This paper is a report of an investigation on the relation between spinal-cord and cauda-equina injuries and sexual potency that has been carried out on these volunteers. A paper on sterility will follow.

### NEUROANATOMY AND PHYSIOLOGY

Despite the traditions and misinterpretations that have sprung up over the years the description of the neuroanatomy and neurophysiology of the activities of the generative apparatus as given by Starling<sup>1</sup> and Sherrington<sup>2</sup> are the basis of all later work. So far as the male is concerned they point out that in animals the sexual reflexes of erection and ejaculation are independent of suprasegmental connections. Erection takes place reflexly as the result of the active dilatation of the vessels of the penis and contraction of the ischiocavernosus muscle, with resultant compression of the dorsal veins of the penis. The vasa deferentia and the seminal vesicles in the cat, for example, are described as being supplied by the sympathetic nerves via the inferior mesenteric and hypogastric plexuses. Starling<sup>1</sup> says that "stimulation of these nerves excites strong contraction of the whole musculature of the vasa deferentia and seminal vesicles, which may be strong enough to cause emission of semen from the penis." The sympathetic system is not the only source of neural impulses, however, because the ischiocavernosus and bulbocavernosus and constrictor urethrae muscles, which not only are involved in the erection of the penis but also assist in the emission of the semen, are supplied by somatic neurones through the internal pudic nerves. The bladder is supplied through the parasympathetic system. They give the origin of these various connections as being in the lumbar and sacral portions of the cord.

So far as man is concerned, Woolsey<sup>3</sup> says no more than that "Priapism is common in high (cord) lesions especially when severe." Frazier and Allen<sup>4</sup> have no comments on this subject. Head and Riddoch<sup>5</sup> also have nothing to say about this aspect

\*From the Paraplegia Service, Cushing Veterans Administration Hospital, Framingham, Massachusetts, and the Department of Neurosurgery, Boston City Hospital.

Presented at the annual meeting of the New England Surgical Society, New Haven, Connecticut, October 1, 1948.

The conclusions and opinions expressed herein are the authors' own and do not necessarily represent those of the Veterans Administration or the United States Army.

†Assistant professor of neurosurgery, Harvard Medical School, associate professor of neurosurgery, Boston University School of Medicine, chief, Department of Neurosurgery, Boston City Hospital.

‡Assistant resident, Free Hospital for Women, formerly resident in surgery, Cushing Veterans Administration Hospital.

§Resident in surgery, Cushing Veterans Administration Hospital.

of cord injuries, nor does Wilson<sup>6</sup> Grinker<sup>7</sup> makes the statement that "fracture (of the first lumbar vertebra) [*sic*] produces loss of sexual function" Fulton<sup>8</sup> follows Sherrington, and Cobb and Coleman<sup>9</sup> deal with the return of sexual function in patients that recovered from spinal-cord injuries only from the point of view of time Kuntz<sup>10</sup> writes that in man the testicles, seminal vesicles, vasa deferentia and epididymis all receive their innervation from the sympathetic system The prostate and prostatic urethra, as well as the corpora cavernosa penis, are innervated by both the sympathetic and the parasympathetic and the corpora cavernosa urethrae and the penile urethra through the communications with the internal pudic nerves in addition He also notes that the voluntary muscles employed in the act of ejaculation—that is, the compressor urethrae and ischiocavernosus and bulbocavernosus muscles—are supplied through the branches of the internal pudic nerves The preganglionic and visceral afferent sympathetic fibers are described as components of the tenth and higher thoracic (up to the sixth) nerves The parasympathetic and internal pudic central connections are said to be through the second, third and fourth sacral segments Kuntz states further

Our knowledge of the role of nerve impulses in the regulatory control of the functions of the male sex organs is based mainly on the findings of the early physiologists The results of animal experimentation however clearly indicate that reflex erection is mediated through centers in the lumbar and sacral segments of the spinal cord and another in the lumbar cord which mediates reflex ejaculation

In general, his conclusions are in agreement with those of Starling and Sherrington cited above, but he leaves the impression that he predicates an ejaculatory center in the lumbar portion of the cord in man He does note however, that "In man voluntary inhibition also plays an important role in sexual excitability and under normal conditions is the controlling factor in sexual behavior"

White and Smithwick<sup>11</sup> quote Kuntz and the older physiologists but in addition point out that Simeone<sup>12</sup> demonstrated in man that if those sympathetic nerves which, when stimulated, cause contraction of the vasa deferentia and the seminal vesicles were paralyzed viable spermatozoa no longer reached the seminal vesicles They also quote Learmonth<sup>13</sup> to the effect that after removal of the superior hypogastric plexus or injury to the first lumbar ganglions the power of ejaculation is lost although the operation does not impair the power of erection or the sensation of orgasm Thus, an abdominal sympathectomy would produce this result They state that in man the central site of the parasympathetic neuron cells is in the anterior horns of the second, third and fourth sacral segments and that the sympathetic preganglionic cells lie in the lower thoracic and upper lumbar levels of the intermediolateral column The somatic connec-

tions are through the anterior horns and the posterior and lateral columns of the second, third and fourth sacral segments

It may be concluded from this evidence that in animals the act of erection is reflex and accomplished by engorgement of vessels of the penis aided by contraction of certain periurethral muscles The nerves involved are the sympathetic and the somatic, and there is said to be a center for erection in the lumbar and sacral portions of the cord Ejaculation takes place reflexly as the result of contraction of the musculature of the vasa deferentia and seminal vesicles aided by voluntary contraction of periurethral muscles The nerves involved are the sympathetic and the somatic, and there is said to be a center for ejaculation in the lumbar portion of the cord The sympathetic connections for these two acts are through the lumbar portion of the cord

In conformity with these data the present opinion appears to be that in men erection takes place as the result of parasympathetic stimulation of the appropriate arterioles, with resultant engorgement of the corpora cavernosa and corpus spongiosum Associated with this there is compression of the efferent veins of these structures by at least the bulbocavernosus and ischiocavernosus muscles The reflex is initiated by either tactile stimuli locally or as the result of psychic stimuli The neural impulses pass both ways over the parasympathetic nerves and the somatic internal pudic nerves The central-nervous-system center lies in the second, third and fourth sacral segments "Ejaculation is not a necessary accompaniment of erection [It is] essentially a reflex reaction" In normal healthy persons the discharge of seminal fluid is elicited only by stimulation of the glans There is thought to be a summation of impulses, which occurs in the spinal cord "When such summation has reached the threshold level a sudden discharge of afferent impulses takes place which calls forth sudden contraction of the smooth musculature of the entire sexual apparatus resulting in the propulsion of seminal fluid into the urethra"<sup>10</sup> Afferent impulses reach the spinal cord over the internal pudic nerves, and efferent impulses travel over the sympathetic nervous system by way of the upper lumbar communicating rami and the hypogastric nerves The presence of seminal fluid in the urethra sets up another reflex with resulting contraction of the constrictor urethrae, bulbocavernosus and ischiocavernosus muscles—all striated and voluntary muscles innervated by the somatic internal pudic nerves The spinal-cord segments that are involved are the second, third and fourth sacral and the upper lumbar In the course of the ejaculatory act the prostate is stimulated, its secretion is added to the semen in the prostatic urethra, and the internal vesicle sphincter contracts, blocking off the bladder<sup>14</sup> Sexual orgasm is associated with

ejaculation and constitutes the sensations caused thereby. It is not known how or where these sensations arise. It need not be assumed that they reach the cerebral cortex. They do, however, give rise to reactions in other visceral organs and the excitation apparently spreads throughout the autonomic nervous system. They also give rise to somatic reflexes in addition to those activating the penurethral muscles and produce spastic contractions of the extensor muscles of the lower extremities.<sup>10</sup>

### MATERIAL

Eighty-four of the paraplegic and paraparetic patients at Cushing Veterans Administration Hospital volunteered for this investigation. Their ages ranged from twenty-one to forty years. In addition certain data on priapism collected over the years by one of us from a personal series of some 320 civilian injuries of the spinal cord and cauda equina have been included. Table 1 shows the distribution of the Veterans Administration cases by level and diagnosis. Seventy of these 84 patients were interviewed personally. Information regarding the other 14 was obtained by letter. Patients diagnosed as suffering from a transection have been divided into two groups, depending upon the accuracy of verification of the diagnosis. In those diagnosed as Anatomic-Visualized Transection (Tr-A) the injury has been actually seen at laminectomy to be one in which there is a complete separation of the cut ends of the cord. In those diagnosed as Clinical-Not Visualized Transection (Tr-C) either the cord injury has not been seen or, if seen, the continuity of the cord was found to be either grossly intact or maintained by intervening scar tissue. The character and length of the clinical course taken by the patients, however, have justified the diagnosis of transection. In both instances, only patients with a complete sensory and voluntary motor loss of function below the level of the cord injury are included as cord transections. Patients diagnosed as suffering from a Partial Cord Injury (P) are those in whom it has been possible to demonstrate some degree of retention of either sensation or voluntary motion, or both in the body and extremities below the level of maximal cord injury. The same diagnostic criteria have been applied to patients with cauda equina (CE) injuries.

The problems of erection, ejaculation and the patient's ability to impregnate his wife were studied in relation not only to the type and level of cord injury but also to how these functions had been affected by anterior dorsolumbar rhizotomy. The significance of certain analogous functions in the interpretation of loss or retention of sexual capacity has also been considered from the point of view of the innervation of the reproductive organs and has been investigated in terms of anal reflex and

type of bladder response to cystometric studies.<sup>15</sup> The figures for these various data are included in Tables 2 and 3.

### Effects of the Type of Cord and Cauda-Equina Injury

*On erections.* Sixty-two or 74 per cent, of the 84 patients had erections after injury. It made no difference so far as the presence of erections was concerned whether the spinal cord or cauda equina was transected or the seat of a partial injury only. One patient with a partial lesion at the level of the

TABLE 1 *Distribution of Cases by Diagnosis and Level of Injury*

DIAGNOSIS	LEVEL OF INJURY				TOTAL
	CERVICAL	THORACIC	LUMBO-SACRAL	CAUDA EQUINAL	
Transection					
Anatomic visualized	0	27	2	0	29

Partial injury	5	1	11	6	23
Totals	6	54	17	7	84

fifth lumbar and first sacral segments and another with a transected cauda equina had no erections. Otherwise the level of injury had no effect on this phenomenon.

*On ejaculations.* Only 8 or 7 per cent of the 84 patients had ejaculations after injury. Only 1 patient with a verified anatomic transection of the cord or cauda equina had an ejaculation. Two patients with clinically diagnosed transection of the thoracic cord, however, as well as 4 patients with partial lesions of the cord and 1 with a partial lesion of the cauda equina did have ejaculations after injury. So far as our experience goes both a transection and a partial injury of the cord will diminish but not eliminate the possibility of ejaculations.

*On ability to impregnate.* Two patients succeeded in impregnating their respective wives after injury. One is reported in detail below. He unquestionably had a transection. There is still a total loss of all sensation and voluntary motion below the sixth thoracic dermatome, his bladder and bowel are reflex and he has involuntary flexor-adductor-extensor muscle spasms of both legs, his abdomen and his back. His clinical condition has not changed for three and three-fourths years. He is able to have intercourse, and has no sensation of orgasm but has an increase in the spasms of his legs and abdomen during ejaculation. He impregnated his wife nineteen months after his injury. The other patient who succeeded in impregnating his wife had a partial injury of the cord at the level of the fifth cervical dermatome. In addition a patient with an anatomic transection at the eleventh and twelfth dorsal segments claims to be able to have intercourse.

From these figures it can at least tentatively be concluded that erections occur after an injury to the cord or cauda equina, regardless of whether either is transected or the seat of only a partial injury, that it is possible for a patient with a transected cord to have ejaculations, that as far as this small series goes, he will have slightly less than 1 out of 10 chances of having ejaculations regardless of the kind of injury, and that neither a transection

be considered competent. For one thing, there are too many uncontrolled psychologic factors with unpredictable influences on such a function.

*On erections* An indication of the effect of this operation on erections can be obtained, however, by a comparison of the known occurrence of this function in patients with and without rhizotomy (Table 2). Twenty-nine, or 34 per cent, of the 84 patients in this series had had anterior rhizotomies,

nor a partial injury of the cord is necessarily a bar to the patient's ability to impregnate his wife.

#### *Effect of Anterior Dorsolumbar Rhizotomy*

Some patients have claimed that the frequency of their erections has been altered for the worse after an anterior dorsolumbar rhizotomy. On the other hand, others have said that the operation has had no such effect, and one has unequivocally stated that whereas before operation he had been unable to produce an erection, erections not only occurred spontaneously but also could be elicited by local stimulation after operation. The operation if properly done divides all the lumbar together with the tenth, eleventh and twelfth thoracic and first sacral anterior roots. Since the division is carried out intrathecally the autonomic as well as the somatic connections made by those roots between the periphery and the central nervous system may be cut. On the other hand, the somatic and parasympathetic segmental nerve supply to the pelvic and reproductive organs is completely spared. It is anatomically possible for either of the above claims to be correct, provided that the observations are competent. In this instance, however, the observations by the patients cannot

22 having suffered from transections and 7 being classed as partial lesions of the cord. All the rhizotomies were done on patients with injuries to the thoracic portion of the cord. Twenty-four, or 83 per cent, had erections before and after operation. Five patients had erections before but not after a rhizotomy. In 3 marked uncontrollable oozing of blood accompanied in 2 by extensive adhesive arachnoiditis and difficulty in identifying the roots to be sectioned may be considered adequate cause for an abnormally extensive denervation with resultant loss of erections. No reason is apparent or can be found to account for the loss of erections in the other 2. Fifty-six, or 66 per cent, did not have a rhizotomy, and 36 (64 per cent) of these patients had erections. Failure to have an erection after rhizotomy, therefore, cannot be traced mathematically to the effect of the operation per se.

Of the 7 patients with partial transections who had had rhizotomies, 1 had been operated upon elsewhere. He had sensation but is said to have had no motion at any time below the level of injury, which was at the eleventh thoracic segment. One had sensation and motion below the cord-injury level at the fourth thoracic segment but

had such severe spasms that rhizotomy with its flaccid paralysis was preferred to the retention of motion with its necessary accompaniment of spasm. In another with an injury at the eighth thoracic segment the voluntary motion was limited to slight activity in the toes only. Sensation was present but reduced. The other 4 patients never had any voluntary motion below the level of the cord injury at any time. Sensation was present

*On ejaculation* The effect of anterior dorso-lumbar rhizotomy on the occurrence of ejaculations is less apparent. Eight of the 84 patients had ejaculations. Five of these had partial injuries at the fifth cervical, twelfth thoracic, second and fifth lumbar segments and the cauda equina, respectively, and 3 had transections at the second, sixth and eighth thoracic segments, respectively. None of these had had a rhizotomy. Twenty-eight

but impaired in these cases. The levels of the injuries were the first thoracic segment in 2 cases and the seventh and eighth thoracic segments in the other 2.

The levels of injury in the patients with transected cords who had erections were the second (1 case), second and third (1 case), third (2 cases), third, fourth and fifth (1 case), fourth (1 case), fifth (1 case), sixth (2 cases), sixth and seventh (1 case), seventh and eighth (1 case), eighth (3 cases), ninth (2 cases), ninth and tenth (1 case), tenth (1 case) and twelfth (1 case) thoracic segments. Two others — both transections, one at the tenth and the other at the tenth and eleventh thoracic segments — did not have erections either before or after rhizotomy. One patient with a transection at the fifth dorsal segment had no erections after a second rhizotomy.

It should be noted that there were examples of loss of both motion and sensation and loss of motion with retention of sensation among the patients who had erections after rhizotomy and that virtually all the thoracic segments of the cord were involved. It appears that the proper performance of an anterior dorsolumbar rhizotomy will not affect the occurrence of erections.

other patients had rhizotomies but have not had ejaculations at any time either before or after the operation. They include the 22 thoracic transections and the 7 partial lesions described in detail above. It is impossible to decide on this evidence whether an anterior dorsolumbar rhizotomy, if properly performed, will or will not prevent ejaculations. What evidence there is seems to favor the view that the operation will not affect their occurrence.

*On pregnancy* Neither of the patients that had produced a pregnancy had had a rhizotomy.

SEGMENTAL INNERVATION OF THE MALE ORGANS OF GENERATION

“Reflex erection in animals is mediated through centers in the lumbar and sacral segments of the spinal cord and ejaculation through another in the lumbar cord.”<sup>10</sup> In man the demonstration of an anal reflex establishes the integrity of the internal pudic nerves — a somatic connection — and their sensory and motor distribution. The presence of a reflex bladder confirms this and also demonstrates the integrity of the parasympathetic plexuses and their central and peripheral connections. These neural pathways are known to have their central

connections in the sacral portion of the cord. It is impossible on the available evidence to be certain of the functions mediated by the sympathetic connections to the pelvic and genital organs in man even though there is increasing evidence that, in some patients at least, disorganization of sympathetic responses throughout the body is connected with distention of the bladder.<sup>16</sup> These neural pathways are known to have their central connections in the lumbar portion of the cord. If the above statements hold true and experimental evidence in animals can be applied to man, erections in human beings should occur whenever the lumbar and sacral segments and their somatic and anatomic connections can be shown to be uninjured. They should be absent when the reverse is true—that is, when the anal reflex is absent, and the bladder is atonic or autonomous or the sphincter atonic.

Six cervical, 40 thoracic (29 transections and 11 partial injuries) and 2 lumbar injuries (1 transection at the second and 1 partial injury at the first lumbar segment) had an anal reflex and either normal or reflex bladders (Table 3). All these patients had erections. On the other hand, 4 patients with transections at the third, sixth and seventh, tenth and tenth and eleventh thoracic segments, 1 with a partial injury at the first lumbar segment and 1 with a partial cauda-equina injury also had anal reflexes and reflex (5) or autonomous (1) bladders but did not have erections. It is thus apparent that with intact somatic and parasympathetic neural connections between the pelvic and reproductive organs and the sacral segments erections were present in 48 and did not occur in 6 cases. Moreover, despite evidence of both transection and partial injury to the thoracic and lumbar segments of the cord erections did occur.

Eleven patients who did not have an anal reflex and had atonic (1) or autonomous (10) bladders had erections as follows: 1 with a partial injury at the twelfth thoracic segment, 1 with a transection at the first lumbar segment, 4 with partial injuries at the first, second, third and fifth lumbar segments, and 5 with partial lesions of the cauda equina. Thus in 11 cases in which the evidence is unquestionably in favor of at least partial denervation of the pelvic and reproductive organs by major damage to their central connections, including virtually all the lumbar segments as well as the cauda equina, erections were nevertheless present. Twelve other patients—3 with transections at the fifth and sixth, sixth and eleventh thoracic segments, respectively, 1 with a partial injury at the twelfth thoracic segment, 3 with transections at the first thoracic segment, and 5 with partial injuries at the twelfth thoracic and first lumbar, first, second and third lumbar and fifth lumbar and first sacral segments gave evidence of interrupted parasympathetic and

somatic connections in that they had no anal reflex and atonic (1) and autonomous (11) bladders. They also had no erections. Attention is again called to the 28 patients with transections of the thoracic segment and the 7 with partial injuries of the thoracic segments who had rhizotomies. In all the patients with transections the pelvic and reproductive organs were cut off not only from all suprasegmental connections but also from the motor side of the lumbar cord. All but 1 of these patients had an anal reflex, and all but 3 (2 autonomous and 1 chemical cystitis) reflex bladders. All but 5 had erections. The same observation held true in the partial injuries so far as the anal reflex and the bladder went. Moreover, sensation in the body and extremities below the upper level of cord injury was present to some extent. All these patients had erections. On this evidence, therefore, it appears that in man erections may or may not occur in the presence of intact somatic and parasympathetic segmental connections between the central nervous system and the pelvic and reproductive organs. Furthermore, an intact lumbar cord and its motor connections are not necessary for their production. Clinical absence of such connections as evidenced by an absent anal reflex and an atonic or autonomous bladder is not necessarily a bar to the presence of erections.

The same criteria can be used to measure the integrity of these neural connections in relation to the occurrence of ejaculations. As noted above, ejaculations were absent in all but 8 cases. One patient with a partial lesion of the fifth cervical segment, 3 with transecting lesions of the second, sixth and eighth thoracic segments, 1 with a partial lesion of the twelfth thoracic segment, 2 with partial lesions of the second and fifth lumbar segments, and 1 with a partial lesion of the cauda equina had ejaculations. None had had a rhizotomy. The patient with the cervical lesion and the 3 with thoracic transections had reflex, but all the rest had autonomous bladders. Six of these patients had had an anal reflex, which was absent in the others. The patients with partial injury at the fifth cervical and transection at the sixth thoracic segment impregnated their wives. Patients with injuries similar in level and pathology and with both absent and present anal reflexes, as well as both reflex and autonomous bladders and with and without rhizotomies, did not have ejaculations. If it is true that to have an ejaculation the periurethral muscles must be innervated and at least reflexly active by way of the internal pudic nerves and if there is no other strictly anatomic factor involved, only patients with totally destructive lesions of the sacral or at most the lumbosacral segments of the cord or with transecting or totally destructive lesions of the cauda equina should be unable to have ejaculations. Thus, none of these patients in this series

who had ejaculations would necessarily be deprived of that ability (since they had only partial lesions) It is impossible to be certain in any given cord injury, however, how far below the level of maximum damage the lesion has extended A level at the first lumbar segment, for example, may have produced changes that are undemonstrable clinically at any point down to the tip of the conus Such a hypothesis would account for the fact that 2 patients with signs of transection at the tenth and eleventh thoracic segments, respectively, and 1 with a partial lesion at the twelfth thoracic segment had absent anal reflexes, autonomous bladders and no ejaculations At least one of them (at the eleventh thoracic segment) was known to have an extensive atrophy of all the cord below the level of transection On the other hand, 2 patients with verified transections at the sixth and seventh and tenth and eleventh thoracic segments, as well as 1 with a clinical transection at the tenth thoracic segment, also had no ejaculations but *did* have an anal reflex and reflex bladders It appears that, unlike the function in animals, the ability to have an ejaculation in man does not rest solely on an intact upper lumbar segment of the cord

PRIAPISM

Priapism "persistent abnormal erection of the penis, usually without sexual desire"<sup>17</sup> There is a medical tradition — undocumented to be sure — that priapism may be expected constantly to accompany severe cervical cord injuries In times past, this relation has been considered to be of diagnostic significance An analysis of 320 injuries of the spinal cord and cauda equina demonstrates that these beliefs are not in accordance with the facts A note regarding the presence of priapism was made in 221 male patients of the total series of 320 There were 122 injuries of the cervical segments, 46 of the thoracic, 21 of the lumbosacral and 34 of the cauda equina Priapism was present in 22 or 10 per cent. It was most common in the cervical group, appearing in 17 cases, or 14 per cent It was also present in all the other groups as follows thoracic, 3 out of 46, or 6.5 per cent, lumbosacral, 1 out of 21, or 5 per cent, and cauda equina, 1 out of 34, or 3 per cent It is undoubtedly of pathologic significance when it does occur It is apparent from these figures that priapism may occur in association with a spinal-cord or cauda-equina injury at any level It occurs most frequently as an accompaniment of cord injuries of the cervical segment but not frequently enough to be of any diagnostic significance

CASE REPORT

Because of its importance to other paraplegic patients the following account of a paraplegic patient's successful impregnation of his wife is included The details have been furnished by the

couple, and the text that follows has been reviewed by them and has their approval

This patient, now 27 years of age, was injured in October, 1944, by a bomb fragment, which struck him in the region of the sixth and seventh thoracic vertebrae As a result he developed a complete motor and sensory paralysis below the level of the xiphoid A laminectomy was performed in September, 1945, and the cord was described in the report of this operation as being discolored and closely adherent to the surrounding scarred dura but without obvious anatomic transection There has been no return of function since the injury

Before and after this laminectomy he had moderately severe leg and abdominal spasm, for which rhizotomy had been recommended and refused

Three months after the injury his urethral catheter, which he had worn till then, was removed He has been able to void since then by manual compression of the bladder but maintains nevertheless, varying amounts of residual urine A transurethral resection of the internal sphincter was advised but refused

About 1 month after injury he began to have spontaneous erections lasting from 1 to 20 minutes They had no relation to cerebral activity The patient then discovered that erections could be caused by local stimulation of the penis About 10 months after injury he attempted masturbation for the first time After this stimulation he obtained a brownish-red ejaculate A week later he repeated the procedure with essentially the same result Since then ejaculations have been described as being normal in appearance, substance and quantity During ejaculation, the patient's spasms increase momentarily, but no other sensation occurs

He was married to a nurse, aged 25 years, in May, 1946 Intercourse was timed to correspond with his wife's periods of intermenstrual pain (Mittelschmerz) His wife's last menstrual period prior to delivery began on May 31, 1946, and she was delivered of a normal, full-term child on March 1, 1947

DISCUSSION

When the material that has been collected as the result of this study (Table 4) is applied to the few observations hitherto made on man and to the deduc-

tions made from animal experiments, it is evident that except for certain details the mechanism of erection and ejaculation as described by Kuntz is correct.

Erections

It is apparent from our series and from earlier studies of bladder innervation that erection takes place on a purely segmental-reflex basis and that suprasegmental connections are unnecessary In paraplegic patients the afferent sensory impulses that initiate the reflex are caused by tactile stimula-

tion of the glans and travel to the second, third and fourth sacral segments by way of the internal pudic nerves. Efferent impulses leave these same segments by way of the parasympathetic supply and cause dilatation of the arterioles of the penis, with distention and congestion of the corpora cavernosa and spongiosum. In addition, efferent impulses leave the same segments over the internal pudic nerves to cause contraction of the periurethral muscles, with resultant compression of the venous drainage channels of the penis.

Our series indicates that destruction of the sacral segment of the cord or transection and destruction of the cauda equina and the pelvic parasympathetic plexuses are the only neurologic, anatomic lesions that will prevent the occurrence of erections. Associated with such absence will be an autonomous bladder, an absent anal reflex and possibly atonic urethral sphincters. Erections occur in the presence of all other cord injuries, whether partial or transecting, and regardless of the level involved.

### *Ejaculations*

Our series indicates that ejaculation is basically a complex purely spinal segmental reflex function. Suprasegmental connections are not necessary for the act. Our findings differ from those of Kuntz and others in that we believe our evidence indicates that destruction or maintenance of the low thoracic and high lumbar sympathetic central connections is the important link in this particular neurologic chain. In this connection we have demonstrated that ejaculations were absent in 28 low thoracic and upper lumbar transections between the sixth thoracic and third lumbar segments. Moreover, of those patients in whom ejaculations were present the injury, except in 1 patient with a transection at the eighth thoracic segment, was outside this area. Two patients, 1 with a transection of the sacral segment and another with a transection of the cauda equina, as well as a patient with a partial lesion at the fifth lumbar segment, had no ejaculations. Otherwise identical cord injuries produced ejaculations in 1 case but not in another.

We interpret these data to mean that to prevent ejaculations the cord damage must be between the sixth thoracic and third lumbar segments and must be extensive within these limits. Since it may be accepted as fact that the impulses that control the first part of the ejaculatory act travel over the sympathetic nervous system, we believe that it is not so much the cord damage in general that acts as a preventive but rather its location and extent within the cord. In support of this contention, in part at least, we call attention to the fact that although no patient with a transection who had had ejaculations had had an anterior dorsolumbar rhizotomy, there were 54 patients who had not had a rhizotomy, as well as 28 who had, that had no ejaculations either before or after the operation.

Such rhizotomies divide all efferent sympathetic connections from the eleventh dorsal through the first sacral segment, and may effectively prevent ejaculation. On the other hand, the tremendous overlap of the sympathetic supply is well known and might serve to maintain neurologic connections between the central nervous system and the smooth musculature of the seminal vesicles, the vasa deferentia and the ejaculatory ducts in spite of such widespread sympathetic denervation.

The second step in ejaculation is also basically reflex, is initiated, according to Kuntz and others, by the sensory impulses set up by the presence of semen in the posterior urethra and sets off efferent impulses, which innervate the periurethral muscles and which result in the actual ejaculation of the semen from the meatus. These afferent and efferent impulses travel over the internal pudic nerves by way of the second, third and fourth sacral segments. As would be expected, the patients with transections of the sacral segments and the cauda equina had no ejaculations.

Our evidence indicates that ejaculations will be prevented by a destructive lesion of the sacral segments of the cord or a transecting lesion of the cauda equina. If the damage is extensive enough and properly placed in the cord ejaculation will also be prevented by either transecting or partial injuries of the cord between the sixth thoracic and third lumbar segments, depending upon the degree of destruction of the sympathetic components in this area of the cord. Complete detachment of the sympathetic system from the anterior aspect of the cord between the eleventh thoracic and first sacral segments may or may not prevent ejaculation, the evidence being inconclusive at present. There is no "center" for ejaculation in the lumbar portion of the cord or anywhere else.

### *The Orgasm*

We have no data on the occurrence of an orgasm in connection with ejaculation except in the case reported above in detail. This suggests that a thoracic transection will do away with the sensation of orgasm and that orgasm of the male is not essential for successful impregnation.

### *Sterility*

To impregnate successfully, the semen must have an adequate count of viable motile spermatozoa. The question arises whether or not spinal-cord injuries affect this aspect of the problem. It is known that the spermatozoa are stored in the seminal vesicles, having been transferred there by the ciliary action of the vas deferens. It is not known whether muscular contractions are necessary in addition. In any event, it appears to be true that any strictly neural activity that takes place does so by way of the sympathetic system, which is known to supply the vasa, the vesicles, the prostate and ejaculatory

ducts. A more detailed study of this aspect of the problem will follow in a later paper.

### CONCLUSIONS

It seems reasonable to conclude until more extensive studies can be made that, unless he has a destructive lesion of the sacral cord, a transection of the cauda equina or injury to the cord between the sixth thoracic and third lumbar segments extensive enough to interrupt completely the thoracolumbar sympathetic outflow, a patient can and should be potent—that is, he should be able to have erections and to ejaculate—and that unless other abnormalities prevent it, he will be fertile and capable of producing pregnancy.

## OBSERVATIONS ON THE ETIOLOGIC RELATIONSHIP OF ACHYLIA GASTRICA TO PERNICIOUS ANEMIA\*

### X Activity of Vitamin B<sub>12</sub> as Food (Extrinsic) Factor

LIONEL BERK, M.D.,† WILLIAM B. CASTLE, M.D.,‡ ARNOLD D. WELCH, M.D.,§ ROBERT W. HEINLE, M.D.,||  
RUDOLF ANKER, Ph.D. || AND MARTIN EPSTEIN, M.D.\*\*

BOSTON, MASSACHUSETTS, AND CLEVELAND, OHIO

IT HAS been shown that various foods—for example, beef skeletal muscle,<sup>1</sup> milk<sup>2</sup> and eggs<sup>3</sup>—contain a heat-stable, unidentified substance,<sup>4</sup> the so-called extrinsic factor. When such a source of extrinsic factor as beef muscle is ingested by a patient with pernicious anemia, untreated or in relapse, it produces little or no hematopoietic effect unless normal human gastric juice is also administered, either simultaneously or at least within six hours.<sup>5</sup> The very small amount of the gastric secretion of the patient with pernicious anemia thus apparently supplies little or none of the heat-labile

substance, possibly an enzyme,<sup>6-8</sup> that is responsible for the activity of the so-called intrinsic factor of normal human gastric juice when administered with beef muscle. Gastric juice when given without opportunity for contact with beef muscle or with components of an unrestricted diet possesses no hematopoietic power.<sup>5</sup> Despite claims to the contrary,<sup>9</sup> incubation of mixtures of beef muscle and gastric juice does not produce the heat-stable, antipernicious-anemia principle of liver *in vitro*.<sup>6</sup> Although there is reason to believe that contact between beef muscle and gastric juice at or near a neutral reaction within the intestinal tract is required for hematopoiesis,<sup>6</sup> attempts to concentrate hematopoietic substances from incubated mixtures of beef muscle and gastric juice have given inconsistent results at best. These observations are compatible with the theory that the patient with pernicious anemia requires intrinsic factor to utilize extrinsic factor at some stage in the production of the antipernicious-anemia principle of liver, but that a direct reaction between extrinsic and intrinsic factors does not necessarily occur.

Extrinsic factor is presently recognizable only by virtue of its hematopoietic potency upon oral administration in pernicious anemia with normal

human gastric juice. Consequently, we have assumed as a working hypothesis that the greatly increased hematopoietic activity in pernicious anemia of liver<sup>10</sup> and of relatively crude liver extracts<sup>11</sup> when ingested with normal human gastric juice indicated the presence of both the extrinsic factor and the antipernicious-anemia principle. Recently, however, we have found that refined liver extracts when given by mouth are also potentiated in their hematopoietic activity by gastric juice, as shown by the following observation, which as conducted according to the methods referred to below.

A patient with pernicious anemia and an initial red-cell count of 2,540,000 was given 1 cc of solution of liver extract, purified (Lederle), containing

neutralized normal human gastric juice to each patient. The methods of dietary control, of obtaining normal human gastric juice and of blood study employed in these observations have previously been described,<sup>1, 5</sup> as has the interpretation of successive reticulocyte responses.<sup>15</sup> Particular attention was paid to administering the gastric juice at times as widely separated as possible from meals to minimize possible contact between the patient's food and the gastric juice. As an additional control on any hematopoietic effect of the gastric juice on the food, 3 patients (Cases 102, 103 and 104) received gastric juice during the first period twelve hours before each dose of vitamin B<sub>12</sub>.

As shown in Table 1, in each case a reticulocyte response was observed during Period II. Except in

TABLE 1 *Potentialization of Hematopoietic Activity of Orally Administered Vitamin B<sub>12</sub> by Normal Human Gastric Juice*

CASE No	TEN-DAY PERIOD No	RED CELL COUNT		RETICULOCYTE PEAK		DAILY THERAPY*
		INITIAL $\times 10^6$	FINAL $\times 10^6$	%	day	
101	I	1.56	1.91	5.7	8	5 gamma of vitamin B <sub>12</sub> † at 8 p m
	II	1.82	2.72	9.3	7	5 gamma of vitamin B <sub>12</sub> and 150 cc. of gastric juice at 8 p m
102	I	1.79	1.74	2.5	10	5 gamma of vitamin B <sub>12</sub> † at 8 a m. at 8 p m. 125 cc. of gastric juice
	II	1.65	2.45	16.7	7	5 gamma of vitamin B <sub>12</sub> and 150 cc. of gastric juice at 8 p m.
103	I	1.62	2.12	none	none	5 gamma of vitamin B <sub>12</sub> † at 8 a m. at 8 p m. 150 cc. of gastric juice
	II	1.90	2.54	3.8	8	5 gamma of vitamin B <sub>12</sub> and 150 cc. of gastric juice at 8 p m.
104	I	2.16	1.93	none	none	5 gamma of vitamin B <sub>12</sub> † at 9 a m. at 9 p m. 125 cc. of gastric juice
	II	2.14	2.10	3.8	10	5 gamma of vitamin B <sub>12</sub> and 125 cc. of gastric juice at 9 p m.
	III	1.91	2.57	14.0	8	5 gamma of vitamin B <sub>12</sub> intramuscularly

\*Given orally unless otherwise indicated.

†Suspended in 125 or 150 cc of physiologic saline solution.

15 USP units (injectable), daily by mouth for ten days. A reticulocyte peak of 3.4 per cent was attained on the seventh day. During a second consecutive ten-day period, the simultaneous administration of normal human gastric juice with the same amount of liver extract produced a second reticulocyte peak of 6.6 per cent at an initial red-cell level of 2,980,000. In other patients it was shown that hydrolysis of liver extracts with dilute sulfuric acid, which apparently destroyed most of the antipernicious-anemia principle, also prevented the material from being potentiated by normal human gastric juice.

With the isolation<sup>12</sup> of crystalline vitamin B<sub>12</sub>, which behaves so far as is now known like the classic antipernicious-anemia principle of liver,<sup>13, 14</sup> the effect of normal human gastric juice on the activity of the pure substance when orally administered could for the first time be tested. Accordingly, 5 microgm of vitamin B<sub>12</sub>\* dissolved in 125 or 150 cc of physiologic saline solution was given daily by mouth during a first ten-day period to 4 patients with untreated pernicious anemia. Immediately thereafter in a second ten-day period, the same amount of vitamin B<sub>12</sub> was given by mouth simultaneously with 125 or 150 cc of previously

Case 104, this was accompanied by a significant increase of red cells and indicates the greater hematopoietic effect of vitamin B<sub>12</sub> given simultaneously with normal human gastric juice. The reticulocyte peaks were not marked in Period II of Cases 103 and 104. However, no hematopoietic effect whatever was noted during Period I, and significant clinical improvement did not begin until the reticulocyte response appeared in Period II of the observations on these 2 patients. In Case 104, during Period III, 5 gamma of vitamin B<sub>12</sub> was given intramuscularly daily. This resulted in a striking second reticulocyte response.

## CONCLUSIONS

These observations indicate that the hematopoietic activity in pernicious anemia of orally administered vitamin B<sub>12</sub> is potentiated by the simultaneous administration of normal human gastric juice but, as with liver extracts, is not so great as the activity of the vitamin B<sub>12</sub> when given parenterally. It is suggested, therefore, that the food (extrinsic) factor may be identical with or closely related chemically to the antipernicious-anemia principle of liver, which is itself presumably identical with vitamin B<sub>12</sub>. It is further suggested that the gastric

\*Kindly supplied for clinical use by Dr. Augustus Gibson of Merck and Company Incorporated Rahway, New Jersey.

(intrinsic) factor is necessary for the optimal utilization of the relatively small amounts of vitamin B<sub>12</sub> or of chemically related substances present in various foods

Preliminary microbiologic findings with the use of *Lactobacillus leichmanni* (A T C C 4797) in an untreated patient with pernicious anemia suggest that the fecal elimination of vitamin B<sub>12</sub> is of such magnitude that either the vitamin derived from the food, or more probably that synthesized by intestinal bacteria, is not absorbed in sufficient amounts to abolish the deficiency (Since this manuscript was submitted for publication Bethell and his associates<sup>16</sup> have reported the results of microbiologic observations demonstrating large daily fecal excretions of vitamin B<sub>12</sub> in 4 cases of untreated pernicious anemia, and from this fact have drawn similar conclusions) Other observations suggest that material soluble in 70 per cent alcoholic extracts of beef muscle, a classic source of extrinsic factor, when prepared in a form suitable for parenteral administration, possesses both microbiologic activity as vitamin B<sub>12</sub> and hematopoietic activity upon intravenous injection in pernicious anemia. It is therefore possible that the function of the intrinsic factor of normal human gastric juice is to facilitate the absorption by the intestine of vitamin B<sub>12</sub> or of chemically related compounds in the food, rather than to react with the extrinsic factor as hitherto assumed

#### DIPHThERITIC MYOCARDITIS\*

NORMAN H BOYER, M D,† AND LOUIS WEINSTEIN, M D‡

BOSTON

DIPHThERIA has shown a striking rise in incidence over the entire world in the last five years. Although the rate of occurrence in the United States as a whole has remained at a static level during this period, some parts of the country have experienced a disturbing increase. In Massachusetts, for example, the number of cases has risen from 123 in 1941 to 439 in 1946 and 440 in 1947. This change, together with the prevalence of the disease in the armed forces in various areas of the world during the war, has aroused again an interest in the study of this infection. The purpose of this report is to re-emphasize the important effects of diphtheria on the heart as determined by electrocardiographic examination.

\*From the Haynes Memorial and the Evans Memorial, Massachusetts Memorial Hospitals, and the Department of Medicine, Boston University School of Medicine.

†Assistant professor of medicine, Boston University School of Medicine, visiting physician, Medical Service, Massachusetts Memorial Hospitals, Physician-in-charge, Cardiac Clinic, Massachusetts Memorial Hospitals.

‡Assistant professor of medicine, Boston University School of Medicine, instructor in infectious diseases, Harvard Medical School, physician and chief of service, Haynes Memorial and assistant member, Robert Dawson Evans Memorial, Massachusetts Memorial Hospitals.

The cases of diphtheria reported below occurred mainly in 1946 and 1947, some patients observed in the preceding two years and a few admitted in the early part of 1948 are included. During this period 140 patients with diphtheria were admitted to the Haynes Memorial Hospital (the Infectious Disease Department of the Massachusetts Memorial Hospitals), electrocardiograms were taken at periodic intervals in all cases. Casual electrocardiographic examination through the course of the disease was shown to be wholly inadequate because it was observed that changes might occur in the first few days of the disease or not until after several weeks and were not infrequently very transient. It became evident that, to demonstrate short-lived variations from the normal, electrocardiograms had to be made almost daily from the time of admission to the hospital until convalescence was well established. This point deserves special emphasis because without fre-

quently repeated studies a true estimate of the occurrence of diphtheritic myocarditis cannot be made. That such a practice is not widely adopted is borne out in the report of Kay and Livingood<sup>1</sup> on the cardiac complications of diphtheria of the skin. These investigators recommended that tracings be taken in mild cases about every two weeks until three weeks after the cutaneous lesions have begun to heal and every week or ten days until about seven weeks after the onset of the lesions in patients with severe cutaneous diphtheria.

In the beginning, our failure to appreciate the need for frequent electrocardiograms necessitated the elimination of 47 patients from our series because of too few tracings. Arbitrarily, five records

aberrations of the ST segments or T waves. Usually several, or all, of these abnormalities occurred simultaneously or appeared in successive records on the same patient. Particular care was taken to exclude any unusual findings that might reasonably be attributed to tachycardia during the early toxic phase of diphtheria or to serum reactions.

Figure 1 illustrates Grade 1 changes in 3 patients. These consist of lowering or flattening of the T waves with sagging of the ST segments, although they may occur in all leads, they were considered significant only when present in Leads 1 and 4.

Figure 2 shows Grade 2 alterations in 2 cases. In the first (G C), the ST segments were displaced, and there was slight prolongation of the PR inter-

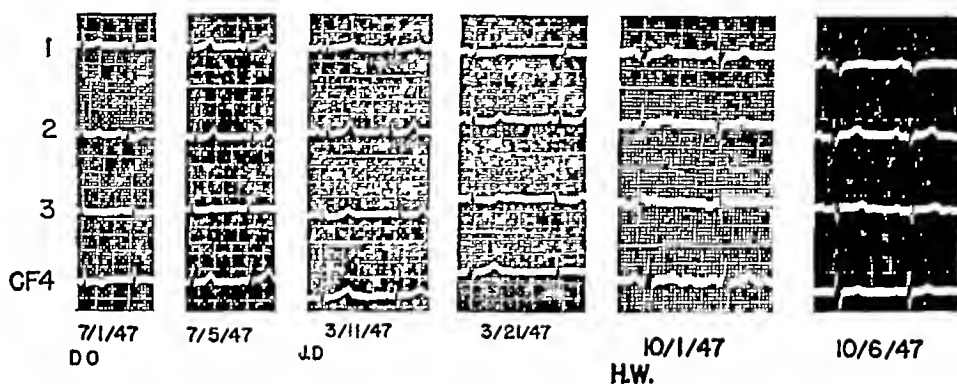

FIGURE 1 Grade 1 Changes

*D O*, a twenty-three-year-old woman, was admitted to the hospital on the third day of disease. She received 50,000 units of antitoxin. On the sixth day of illness the ST segments showed slight sagging. By the fourteenth day changes in the T waves had become maximal and are shown over the date "7/1/47". Four days later the record was normal and remained so. There were no other signs of cardiac involvement.

*J D*, a fifteen-year-old boy, was admitted to the hospital on the tenth day of disease, he received 20,000 units of antitoxin. The record on the fourteenth day of disease was considered within normal limits. On the eighteenth day ST-segment changes appeared and were maximal on the twenty-fifth day. The electrocardiogram was slightly abnormal at discharge on the fifty-third day. There were no other signs of cardiac involvement.

*H W*, a forty-eight-year-old woman, was admitted to the hospital on the fourth day of disease. She was given 20,000 units of antitoxin. The record on the fifth day of the disease was considered normal. Minor T-wave changes appeared on the ninth day and had become maximal on the twelfth day. Changes persisted until the twenty-fourth day. No other signs of cardiac involvement appeared.

taken during the course of the illness were considered the minimum adequate number, although it is almost certain that in some cases this was wholly inadequate for discovering transient changes. The cases were unselected, so that both severe and mild ones were included.

The degree of electrocardiographic abnormality was graded from 1 to 4. Grade 1 consisted of prolongation of the PR or QT intervals, or slight alterations in the ST segment or T wave. Grade 2 variations were either more marked or consisted of a combination of those classified as Grade 1. Grade 3 was made up of records showing the same changes as those in Grade 2 (but more intense), whereas the designation of Grade 4 was reserved for cases of complete auriculoventricular block, bundle-branch block, ventricular tachycardia or very marked

val. This was the only case of reciprocal displacement of the ST segments. In all the others the ST segments were directed downward in all the affected leads.

Figure 2 exemplifies the characteristic change in the ST segments and T wave, which is very similar to that produced by digitals. In addition there are "splintering" without widening of the QRS complex and development of deep S waves in Leads 2 and 3.

The electrocardiograms characteristic of Grade 3 are presented in Figure 3. The earliest detectable abnormality, prolongation of the QT interval, appeared on the seventh day of the disease. This was soon followed by progressive sagging of the ST segments and an increasing degree of inversion of the T waves in Leads 1, 2 and CF<sub>4</sub>, which per-

sisted until the patient's death on the forty-seventh day after the onset of diphtheria. Aside from some increase in heart size, there were no signs of cardiac involvement, such as murmurs or gallop, and no congestive phenomena. Autopsy showed very marked generalized fibrosis, but, by that time, all the inflammatory cellular reaction had subsided.

Figure 4 is an example of Grade 4 since it demonstrates complete auriculoventricular block, there are also marked ST-segment and T-wave changes. This patient died of bronchopneumonia on the forty-seventh day. The record taken on the day before death showed considerable improvement. Histologic examination of the myocardium revealed widespread fibrosis, however.

Grade 4 electrocardiograms of 4 patients are illustrated in Figure 5. These tracings reveal the most severe abnormalities — namely, ventricular tachycardia, complete auriculoventricular block, and widened QRS complexes. The widened QRS complexes in patients R H and R G may have been due either to bundle-branch block or to origin of the impulse somewhere below the junctional tissue. The only patient who developed auricular

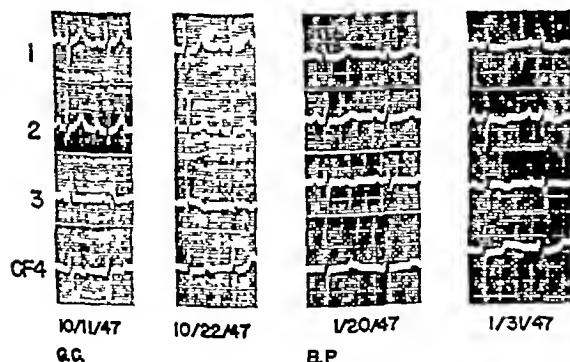

FIGURE 2 Grade 2 Changes

G C, a five-year-old girl, was admitted to the hospital on the third day of disease. She received 20,000 units of antitoxin. The record labeled "10/11/47" was taken on the fourth day of disease and was normal. Maximal ST changes were recorded on October 22. Two days later the ST segments had returned to normal, but the QT interval was prolonged. A record on October 30 was normal. There were no other signs of cardiac involvement.

B P, an eleven-year-old girl was admitted to the hospital on the sixth day of disease. She was given 50,000 units of antitoxin. The first record to be made (marked "1/20/47") was on the eleventh day of disease. The QT interval was prolonged, but otherwise the record was normal. Two days later ST-segment changes appeared and became maximal. The record became normal on the thirty-eighth day of disease. From the twenty-first to the twenty-third day gallop rhythm, an apical systolic murmur and frequent premature beats were present.

fibrillation (preceded by flutter) was G C. She also had complete auriculoventricular block since the ventricular rate was 115 and regular. The voltage of the QRS complexes decreased markedly from that found in earlier records, and comparatively deep S waves appeared in Lead I.

Table 1 indicates the relative frequency of electrocardiographic abnormalities during the course of diphtheria. Seventeen (18.2 per cent) of the 93 patients showed normal records throughout. It should be noted, however, that the average number of records per patient in this group was only seven, and only 4 of the 17 patients had more than eight. In view of the transient nature of the changes with myocardial involvement, it seems probable that, had more tracings been made, significant variations

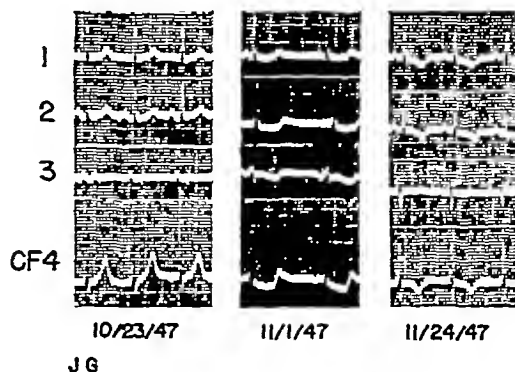

FIGURE 3 Grade 3 Changes

J G, a fifty-two-year-old man, was admitted to the hospital on the fourth day of disease. He received 100,000 units of antitoxin. The record dated "10/23/47" was made on the fifth day of disease and was normal. Two days later the QT interval was prolonged, and auricular premature beats appeared. Progressive ST-segment changes appeared and reached their maximum on November 1 — shown above. As the ST segment changes regressed progressive T-wave inversion appeared, reaching maximum inversion on November 24. These changes persisted until death on the forty-seventh day of disease. The heart size was increased on both physical and x-ray examination, but there were no other signs of cardiac involvement. Concomitantly widespread polyneuropathy appeared, and, terminally, signs of bronchopneumonia. Histologic examination showed extremely marked, generalized fibrosis and some muscle fragmentation, but no acute degeneration or inflammatory cellular reaction. The coronary arteries revealed slight intimal thickening but were patent throughout.

would have been detected in cases in which no cardiac dysfunction was apparent.

An almost equal number of patients (16.3 per cent) showed electrocardiographic findings that were neither clearly normal nor abnormal. The main difficulty lay in the interpretation of T-wave changes in Lead CF<sub>4</sub>. Since only one chest lead was taken, alterations in the T waves from day to day could often be attributed to difference in the position of the exploring electrode. Arbitrary standards were adopted as follows: an inverted T wave in Lead CF<sub>4</sub> was accepted as normal if the R/S ratio was less than 1. If the R exceeded the S wave by 50 per cent or more an inverted T wave was considered abnormal. Records that did not fall into either of these categories were considered borderline. Questionable T-wave changes in Lead CF<sub>4</sub> accounted for 9 of the 15 borderline cases. In the remainder the QT interval, ST segments or T

waves showed changes that were probably, although not certainly, significant

Sixty-one patients (65.5 per cent) showed incontestable abnormalities, of these, the majority (65.5 per cent) were slight (Grade 1) and usually transient

The relative frequency of individual abnormalities is illustrated in Table 2. Multiple deviations from the normal were more usual than isolated

(12.5 per cent) who had no laboratory evidence of myocarditis were twenty years of age or older, whereas 30 (50 per cent) of those with abnormal records were over twenty years of age. As well as could be ascertained from the small number of cases in each of the grades of myocardial disease, age did not seem to determine the degree of electrocardiographic aberration.

On the whole the onset of electrocardiographic abnormalities was earlier than has been usually thought, the average being eleven and a half days after the inception of the diphtheria. These figures include patients with abnormal records on admission, the day of admission being counted as the day the electrocardiogram became abnormal. Since 34 per cent were abnormal on admission, with an average duration of disease of nine and three-fourths days, it is apparent that the true average time of onset is less than the above figure indicates. The exact time of the first occurrence of myocardial disease was not known in about a third of the patients, since the electrocardiograms were abnormal on entry into the hospital. The earliest abnormal record was encountered on the third, and the latest on the forty-seventh day of the disease.

The interval between the onset of diphtheria and the institution of antitoxin therapy was not greatly different in the various groups (Table 4). The average delay was only a little greater for patients with abnormal electrocardiograms, but was especially notable in those who developed Grade 4 changes. However, of the 9 patients in the latter category, 2 were not admitted to the hospital until the seventeenth and twenty-first days respectively, these cases weight the average of the group heavily.

The development and evolution of electrocardiographic abnormalities did not appear to be related to the type of organism (Table 5). Gravis strains predominated in patients with Grade 4 findings, the small number of cases makes such an observation of dubious significance, however.

The over-all mortality (Table 6) was 14.4 per cent for the series. There were no deaths among the patients who had normal or borderline electrocardiograms. The number of deaths rose steadily with increase in intensity of the electrocardiographic aberrations, being 5 per cent in the patients with Grade 1, 14 per cent in those with Grade 2, 40 per cent in those with Grade 3 and 78 per cent in those with Grade 4 changes.

#### DISCUSSION

Significant electrocardiographic abnormalities appeared to be much more common in the cases of diphtheria in this series than in those reported in other studies. The usual incidence of myocarditis has been thought to be between 10 and 20 per cent.<sup>2,3</sup> Begg,<sup>4</sup> however, found changes in the electrocardiographic records in 84 per cent of 103 selected cases of severe diphtheria. This figure is

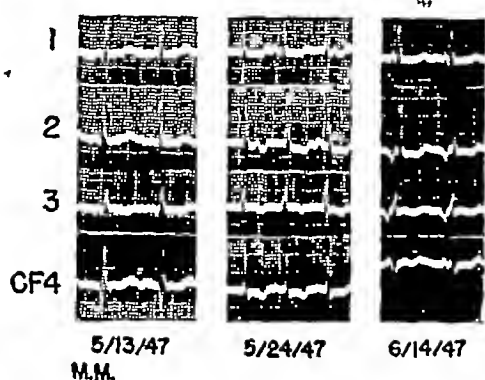

FIGURE 4. Grade 4 Changes

*M.M.*, a fifty-five-year-old woman, was admitted to the hospital on the seventh day of disease. She was given 100,000 units of antitoxin. The record dated "5/13/47" was made the day after admission—the eighth day of disease—and showed prolongation of the QT interval (the precordial lead was reversed). ST-T changes and complete auriculoventricular block appeared in the next few days and remained constant until June 3, when the block disappeared and ST-T reverted toward normal. On the day before death the record dated "6/14/47" was made, showing considerable change toward normal. There were no other signs of cardiac involvement. On the thirty-seventh day of disease polyneuritis developed, with regurgitation of food and inability to swallow. Aspiration pneumonia followed, and death occurred on the forty-seventh day. At autopsy the myocardium showed diffuse fibrosis.

ones, although variations in the ST segment or T waves, or both, not infrequently occurred alone. It is noteworthy that 1 patient, who showed Grade 4 changes (ventricular tachycardia) for a short period, had only minor electrographic findings before and after the period of rapid pulse. This was the only one of the group of patients with myocarditis of the most severe degree who survived.

Data regarding the relation of age to the occurrence of abnormal electrocardiograms are presented in Table 3. About a third of the patients were twenty years of age or over, and two thirds were younger. The average age of those showing significant findings was two and a half times that of those with normal records. Furthermore, the age range was much narrower for those with normal or borderline tracings. The oldest patient with a normal electrocardiogram was thirty years of age, the oldest with borderline variations was thirty-three years, and the oldest with distinct abnormalities seventy-two years old. Only 4 of those

in close agreement with that obtained in our group, which included both severe and mild cases. Frequent electrocardiograms appeared to provide the only certain means of detecting myocarditis,

of 3 patients displayed no abnormalities at any time.

The pathological characteristics of fatal diphtheritic myocarditis have recently been reviewed

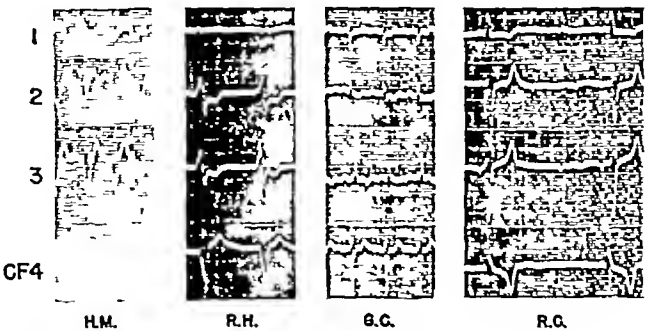

FIGURE 5 Grade 4 Changes

*H. M.*, an eight-year-old boy, was admitted to the hospital in the third week of disease with palatal paralysis and gallop rhythm. The electrocardiogram on admission showed complete auriculoventricular block, with a ventricular rate of 80 and marked ST-T changes. Just before death the record demonstrated ventricular tachycardia.

*R. H.*, an eleven-year-old boy, was admitted to the hospital on the seventeenth day of disease. He was given 10,000 units of antitoxin. Ventricular tachycardia was present on admission. On the day of death the above record was obtained.

*G. C.*, a nine-year-old girl, was admitted to the hospital on the fifth day of disease. She received 60,000 units of antitoxin. The electrocardiogram on the day after admission showed ventricular tachycardia, which persisted for four days. On the next day complete auriculoventricular block, with a ventricular rate of 110 and marked ST changes but with normal QRS complexes, was present. On the following day auricular flutter appeared, followed shortly by auricular fibrillation. After five days the auricular fibrillation disappeared and was replaced by complete auriculoventricular block and progressive QRS changes up to the time of death on the thirty-fifth day.

*R. C.*, a twelve-year-old boy, was admitted to the hospital on the fifth day of disease. He was given 40,000 units of antitoxin. On admission the heart was enlarged, and the rate was 35 per minute. Complete auriculoventricular block and widened QRS complexes were present.

since reliable physical signs of heart disease were never present in patients with the lesser grades of deviation from the normal and those with a high degree of electrocardiographic abnormality often revealed surprisingly little on examination of the cardiovascular system.

As has been stated above, it is possible that many of the normal or borderline cases did not belong

by Gore.<sup>5</sup> The essential features are muscle degeneration and cellular infiltration in the early and diffuse fibrosis with loss of muscle fibers in the later

stages. Progressive fibrosis begins after the third week.<sup>6</sup> Clinicopathological correlation in our cases revealed the following facts. There were no deaths in the group with normal or borderline records.

In those with Grade 1 changes there were 2 deaths, only 1 of which came to autopsy. This patient died of pneumonia due to *Klebsiella pneumoniae* fourteen days after having become ill with diphtheria, autopsy revealed only slight to moderate myocar-

shown in Figure 3. Autopsies were performed in 6 of the 8 fatal cases classified as Grade 4. All showed a high degree of myocardial damage, either acute degenerative or fibrotic, depending upon the duration of the illness.

The view that diphtheritic myocarditis may give rise to difficulty years after recovery has been expressed<sup>5, 6</sup> and denied<sup>7</sup>. The demonstration of marked changes in the heart muscles in fatal cases makes it difficult to escape the conclusion that patients who do not die but who have electrocardiographic abnormalities of relatively the same degree as some of those who expire have lost a fair portion of their myocardium. Even if, for the sake of discussion, the minor degrees of departure from

the normal are considered to be due to reversible processes (the one autopsy in the Grade 1 group refutes this), and if the patients that make up Grade 4 are given a hopeless prognosis for survival past the acute stage of the disease, there still remain the Grade 2 and 3 groups, over three fourths of whom live. Pathological examination of the fatal cases in Grades 3 and 4 revealed severe cardiac damage. Reversibility of the electrocardiographic changes cannot be considered as indicating a return to normal of the myocardium. Figure 4 presents the records of a patient who died of bronchopneumonia on the forty-seventh day of diphtheria. The electrocardiogram taken just before death showed reversion toward normal, and yet at autopsy there was a severe degree of myocardial fibrosis. Despite the marked destruction of muscle fibers the abnormalities had decreased from Grade 4 with complete auriculoventricular block to Grade 2, or perhaps even Grade 1, at the time of death.

Although the evidence indicates that recovery is complete enough in the young patient, it seems illogical to assume that such hearts have a normal reserve for later life, should hypertension or coronary-artery disease make its appearance. The fifteen-year to twenty-year follow-up study of 100 cases reported by Thompson, Golden and White<sup>7</sup> has the objection that the subjects, ranging in age from sixteen to forty-six years, were still young. The obvious drawback in older persons is, of course, that any abnormality may be attributed to coronary-artery disease alone.

The fact that the electrocardiogram returns to normal despite loss of muscle substance and fibrosis is a good demonstration if any more are necessary, of the limitations of the method.

The management of diphtheritic myocarditis revolves mainly about constant and skilled nursing care and maximum rest of the heart. Both quinine and digitalis have theoretical disadvantages, and their place in the therapy of this disease is not clearly defined. The length of time for which the patient should remain completely inactive is a controversial point. Some clinicians believe that bed rest should be continued until the electrocardiogram has become normal again. Since this may require four to six months or longer, it seems unnecessary to insist on rest in bed for a long period particularly since antitoxin and penicillin rid the patient of the injurious agent rapidly and scar formation in the myocardium is usually well established after the third week.<sup>5</sup> In cases in which the electrocardiographic abnormalities have not disappeared completely, it is probably wise to prohibit severe or prolonged effort for several months.

#### SUMMARY

Of 93 patients with diphtheria who had had at least 5 electrocardiograms during the course of the disease, 61 showed abnormal tracings. The remainder were about equally divided between equivocal or borderline changes and normal records.

The degree of abnormality was classified as Grade 1 through 4. Grade 1 changes were found in 40, Grade 2 in 7, Grade 3 in 5, and Grade 4 in 9 patients.

Although the mortality rose sharply with increasing degrees of abnormality, the pathological data available indicated that the anatomic lesions in the heart varied quantitatively rather than qualitatively and that even the lesser degrees of electrocardiographic change were associated with irreversible myocardial lesions.

Neither the type of organism nor delay in antitoxin therapy appeared of any importance in determining the development or degree of electrocardiographic abnormality. The determining factors appeared to be the extent and severity of the local diphtheritic lesion.

Information obtained from autopsied cases showing all types and degrees of normal electrocardiographic patterns indicated that recovery is probably associated with loss of muscle substance and is therefore, never complete. This apparently holds true even in the face of a return of the electrocardiogram to normal.

# THE TREATMENT OF RUPTURED LIVER WITH ABSORBABLE HEMOSTATICS\*

## Report of Three Cases

GEORGE W. PAPEN, M.D.,† AND STANLEY MIKAL, M.D.‡

BOSTON

**S**URGERY of the liver has lagged behind surgical operations on the other abdominal viscera, mainly because of the difficulty of controlling hemorrhage. However, with the recent development of absorbable hemostatic substances in the form of sponges and packs, control of hemorrhage from the liver can be obtained. The purpose of this paper is to present 3 cases of traumatic rupture of the liver in which hemorrhage was controlled with oxycel and gelfoam.

### HISTORICAL REVIEW

In 1888 Langenbuch,<sup>1</sup> with mass ligatures, controlled severe liver hemorrhage following partial resection.

Kousnetzoff and Penski,<sup>2</sup> in 1896, devised a special needle for liver suture. The needle was large, curved, wedge-shaped and blunt tipped. It was passed through the liver with a continuous suture. The suture was subsequently cut up into single mattress sutures and tied. If any large vessels continued to bleed from the cut liver surface they were circumstitched and ligated.

Ceccherelli and Bianchi,<sup>3</sup> in 1894, reported on the use of decalcified bone plates in controlling hemorrhage from the liver. They placed the bone plates on the upper and lower surfaces of the liver and secured them with through-and-through sutures. In a similar manner, Payer used magnesium plates, and Segale ivory rods.<sup>4</sup>

Terrier and Auvray,<sup>5</sup> in 1898, used a continuous-chain-suture technic for hepatic hemostasis, with good results.

In 1902 Beck<sup>6</sup> employed a Nélaton rubber catheter for elastic compression around the cut surface of the liver, together with iodoform gauze as a tampon. The catheter and gauze were brought out through the abdominal wound and removed in four to six days. Later, in the same year, he reported the use of split bands of abdominal wall consisting of fascia, peritoneum and muscle, which were attached to the abdominal wall at one end, the other being used as suture material.

Kocher,<sup>7</sup> in 1902, applied crushing stomach clamps to the cut liver edge. The clamps were brought out through the abdominal wound and removed in forty-eight hours.

In 1905, Cullen<sup>8, 9</sup> used an overlapping-mattress-suture technic with a modified Kousnetzoff needle for controlling hepatic hemorrhage.

Gillette<sup>10</sup> passed five or six sutures of catgut through the entire liver substance, brought them through the chest wall around a rib and tied the sutures on the skin. In 1905 he reported 2 such cases with recovery.

Boljarski,<sup>11</sup> in 1910, used isolated omentum and catgut sutures for control of liver bleeding.

Cushing<sup>12</sup> used striated muscle in neurosurgery as a hemostatic plug and later applied it to liver biopsies, reporting the results in 1911. Striated muscle controlled hemorrhage because thrombokinase liberated by the damaged muscle aided in blood clotting and also the muscle plug by its bulk caused hemostatic compression of the liver sinuses.

In 1915 Grey<sup>13</sup> used sheep's fibrin in small blocks for hemostasis, and Harvey, in 1918,<sup>14</sup> used beef fibrin in small sheets for similar purposes.

Seegers and his co-workers<sup>15, 16</sup> discovered thrombin in 1938 and used it as a hemostatic agent in human beings and animals in the following year.

Ingraham et al.,<sup>17-21</sup> in 1944, used human fibrinogen foam and fibrin foam for hemostasis in neurosurgery and showed the value of these substances in general surgery. They found these products absorbable, nonirritating and more effective in combination with thrombin.

In 1943 Frantz<sup>22</sup> employed oxidized cellulose (oxycel) to arrest hemorrhage from brain, liver, kidney and spleen in animals. The oxidized cellulose was prepared from gauze or cotton and subjected to an oxidation process, which produced cellulosic acid. Hemostasis was a result of the action of this acid, and no advantage was obtained by the use of thrombin with oxycel because thrombin became inactive in an acid medium. The oxycel turned black on contact with blood and was completely absorbed in three or four weeks. It was probably absorbed by phagocytosis and by dissolution as small particles into the blood stream, which were excreted subsequently by the kidneys. Tissue reaction to the oxycel was minimal.<sup>22-25</sup>

Light and Prentice,<sup>26, 27</sup> in 1945, used a gelatin sponge (gelfoam) for hemostasis in surgery. The gelatin sponge was made from ordinary commercial gelatin by the introduction of air into a gelatin solution to obtain a porosity. This sponge was then heated in an oven until dry. The hemostatic

\*From the First Surgical Service, Boston City Hospital and the Department of Surgery, Tufts College Medical School.

†Clinical professor of surgery, Tufts College Medical School; surgeon-in-chief, First Surgical Service, Boston City Hospital.

‡Senior assistant resident, First Surgical Service, Boston City Hospital.

action of the gelatin sponge was twofold: it acted as a tampon and also liberated thromboplastin from damaged platelets that entered its foam structure and became traumatized by contact with the walls of its interstices. Gelfoam was hemostatic when used with or without thrombin and was absorbed in fifteen to twenty-four days with minimal tissue reaction.

Levitski<sup>25</sup> chose a hemostol plug for hemostasis. The hemostol plug was made from relatively fresh coagulated human plasma. He used 100 parts of citrated plasma from blood three to five days old and added 5 parts of calcium chloride to coagulate the plasma. The coagulated plasma was transferred to a sponge, and the serum squeezed out of it. The hemostol plug was inserted into the liver wound for three to five minutes, after which hemostasis and adherence took place. This plug of coagulated human plasma was completely absorbed, and the tissue reaction to it negligible.

In 1946, Lowry<sup>29</sup> used synthetic adhesive tape in treating wounds of the liver. After resecting sections of rabbit livers, he applied two strips of Scotch tape, in the form of an envelope, to the liver. The entrapped clot acted as a plug and controlled the hemorrhage. Small localized encapsulated abscesses or caseous residues surrounded by fibrous tissue were usually found at the end of a month of such treatment.

Jenkins,<sup>30, 31</sup> in 1947, applied gelfoam by a blanket technic to control wounds from the liver in animals; he also applied it to the aorta by a cuff technic and to the vena cava and the heart by a patch technic.

#### INCIDENCE

Thöle<sup>32</sup> collected 752 cases of liver injury and found that a third were due to internal injuries (patient run over by wheel, blow to abdomen and so forth), whereas two thirds were penetrating injuries, such as stab and gunshot wounds. Of Krieg's<sup>33</sup> 60 cases, 83 per cent were of the penetrating type, and only 17 per cent of the subcutaneous type. Anderson<sup>34</sup> found that the liver was injured in 10 per cent of all open wounds of the abdomen, and in 19.5 per cent of internal abdominal injuries. During World War II, Fox<sup>35</sup> reviewed 270 thoraco-abdominal wounds in an American combat hospital in Italy and reported 27 per cent involvement of the liver. The liver was drained in 18 per cent, packed with gauze in 9.7 per cent, sutured in 2.8 per cent and packed with muscle in 1.6 per cent. Of these cases, subphrenic abscesses developed in 6 per cent, intrahepatic abscesses in 1 per cent, subhepatic abscesses in 4 per cent, and biliary peritonitis in 0.7 per cent.

#### MORTALITY

Among 829 patients with wounds of the liver in World War II, Madding<sup>36</sup> reported a mortality of 27 per cent, regardless of the type of treatment.

According to Boljarski,<sup>37</sup> the mortality for penetrating wounds was 30 per cent, whereas that for internal injuries was 88 per cent.

Thöle<sup>32</sup> found the operative mortality in penetrating and internal injuries of the liver to be 39 per cent during the first six hours after injury, 50 per cent after six to twelve hours, 67 per cent after twelve to twenty-four hours and 86 per cent after twenty-four hours.

Boljarski's<sup>37</sup> figures likewise indicate the value of early operation. He reported an operative mortality of 15 per cent during the first three hours after injury and one of 50 per cent twenty-four hours after injury.

Death during the first seventy-two hours after hepatic trauma is usually due to hemorrhage and shock. After the fourth day, it is due to biliary septic peritonitis. Hemorrhage from liver rupture or penetration is severe because the hepatic veins are thin walled, contain very little elastic tissue and have no valves. Bleeding is also prolonged because of the massaging effect of the diaphragm and the admixture of bile with blood, which delays clotting.

#### AMOUNT OF LIVER NECESSARY FOR LIFE

Mann<sup>38</sup> (1927) removed as much as 50 per cent of liver tissue in animals without any serious impairment of liver function. He also demonstrated that liver tissue has remarkable powers of regeneration and recuperation. Ireneus and Puestow,<sup>39</sup> in 1944 removed as much as 90 per cent of liver tissue in dogs in successive intervals with survival. They also showed that the functional reserve of liver is unimpaired after massive blood loss from partially hepatectomized animals. In 1947 Martin<sup>40</sup> disclosed that in dogs the usual functional liver tests, such as bromsulfalein excretion, galactose tolerance, prothrombin time and alkaline phosphatase are not affected to any appreciable extent after massive trauma to the liver when as much as 50 per cent of the liver was damaged.

#### CLASSIFICATION OF LIVER TRAUMA

Liver trauma may be classified according to cause or effect. The classifications of Vance<sup>41</sup> are as follows: percutaneous or penetrating (stab or gunshot wounds), and internal or nonpenetrating (blow or wheel compressing abdomen). Movnihan<sup>42</sup> lists the following as the results of pathologic conditions: rupture of the liver, with laceration of Glisson's capsule, subcapsular hemorrhage, and central rupture with hematoma formation and subsequent development of an abscess or cyst.

#### CASE REPORTS

**CASE 1 (B.C.H. 1258525).** D.L., a 19-year-old boy, was admitted to the hospital on August 26, 1947, with a history of having fallen from a horse-drawn wagon, whose wheels ran over his chest. The patient complained of pain in the right lower lateral portion of the chest wall, right shoulder and right upper quadrant.

In a similar manner, Payer used magnesium plates, and Segale ivory rods.<sup>4</sup>

Terrier and Auvray,<sup>5</sup> in 1898, used a continuous-chain-suture technic for hepatic hemostasis, with good results.

In 1902 Beck<sup>6</sup> employed a Nélaton rubber catheter for elastic compression around the cut surface of the liver, together with iodoform gauze as a tampon. The catheter and gauze were brought out through the abdominal wound and removed in four to six days. Later, in the same year, he reported the use of split bands of abdominal wall consisting of fascia, peritoneum and muscle, which were attached to the abdominal wall at one end, the other being used as suture material.

Kocher,<sup>7</sup> in 1902, applied crushing stomach clamps to the cut liver edge. The clamps were brought out through the abdominal wound and removed in forty-eight hours.

In 1905, Cullen<sup>8,9</sup> used an overlapping-mattress-suture technic with a modified Kousnetzoff needle for controlling hepatic hemorrhage.

Gillette<sup>10</sup> passed five or six sutures of catgut through the entire liver substance, brought them through the chest wall around a rib and tied the sutures on the skin. In 1905 he reported 2 such cases with recovery.

Boljarski,<sup>11</sup> in 1910, used isolated omentum and catgut sutures for control of liver bleeding.

Cushing<sup>12</sup> used striated muscle in neurosurgery as a hemostatic plug and later applied it to liver biopsies, reporting the results in 1911. Striated muscle controlled hemorrhage because thrombokinase liberated by the damaged muscle aided in blood clotting and also the muscle plug by its bulk caused hemostatic compression of the liver sinuses.

In 1915 Grey<sup>13</sup> used sheep's fibrin in small blocks for hemostasis, and Harvey, in 1918,<sup>14</sup> used beef fibrin in small sheets for similar purposes.

Seegers and his co-workers<sup>15,16</sup> discovered thrombin in 1938 and used it as a hemostatic agent in human beings and animals in the following year.

Ingraham et al.,<sup>17-21</sup> in 1944, used human fibrinogen foam and fibrin foam for hemostasis in neurosurgery and showed the value of these substances in general surgery. They found these products absorbable, nonirritating and more effective in combination with thrombin.

In 1943 Frantz<sup>22</sup> employed oxidized cellulose (oxycel) to arrest hemorrhage from brain, liver, kidney and spleen in animals. The oxidized cellulose was prepared from gauze or cotton and subjected to an oxidation process, which produced cellulosic acid. Hemostasis was a result of the action of this acid, and no advantage was obtained by the use of thrombin with oxycel because thrombin became inactive in an acid medium. The oxycel turned black on contact with blood and was completely absorbed in three or four weeks. It was probably absorbed by phagocytosis and by dissolution as small particles into the blood stream, which were excreted subsequently by the kidneys. Tissue reaction to the oxycel was minimal.<sup>22-25</sup>

Light and Prentice,<sup>26,27</sup> in 1945, used a gelatin sponge (gelfoam) for hemostasis in surgery. The gelatin sponge was made from ordinary commercial gelatin by the introduction of air into a gelatin solution to obtain a porosity. This sponge was then heated in an oven until dry. The hemostatic

showing the value of absorbable hemostatics in ruptured livers in human beings. In all cases relatively complete hemostasis was obtained three to five minutes after the laceration had been packed with oxycel and gelfoam and gentle pressure applied. No delayed secondary liver hemorrhage ensued postoperatively. Pulmonary complications such as atelectasis and hydrothorax were common sequelae, and thoracentesis was frequently resorted to. In Case 1, in which the peritoneal cavity was drained, a temporary biliary fistula and subhepatic abscess developed, and thoracotomy with rib resection was required. Postoperative biliary peritonitis or fistula never developed when the abdomen was closed without drainage. Hence, primary closure of the abdomen without drainage is advocated instead of that with drainage.

These cases present relatively simple technics of obtaining hemostasis in bleeding livers. The patient in Case 1 was treated by simple packing and compression of the lacerated liver with oxycel and gelfoam, the patient in Case 2 by loose suture of the oxycel to the liver capsule, and the patient in Case 3 by packing of the lacerated liver with oxycel and suturing of the capsule of the liver to the diaphragm and abdominal wall to prevent the suction effect of the diaphragm on the liver. All three of these methods proved satisfactory in the control of hepatic hemorrhage.

It may be added that though the abdominal approach was used in these cases, some surgeons would choose the thoracic method because of the greater exposure of the dome of the liver obtained. However, when there is trauma to an abdomen, a hollow organ as well as a solid organ may be ruptured. To differentiate hollow-organ perforation and solid-organ rupture is often difficult, and the two frequently occur simultaneously. Hence, if jejunum, ileum or colon is perforated and the liver ruptured, an abdominal approach will give better exposure to these structures situated in the middle or lower portion of the abdomen. If greater exposure of the superior surface of the liver is required, a combined abdominothoracic incision is indicated.

### SUMMARY

A brief history of control of liver hemorrhage in surgery is presented, and 3 cases of traumatic rupture of the liver in human beings successfully treated with oxycel and gelfoam are reported.

The treatment recommended for large or jagged lacerations of the liver is packing of the laceration with absorbable hemostatic sponges (gelfoam, oxycel, fibrin foam or fibrinogen foam).

These hemostatic packs may be held in place by simple pressure, suture to the liver capsule or suture of the liver capsule to the diaphragm and abdominal wall.

Closure of the abdomen without drainage is advocated because it lessens the chance of external infection along the drainage pathway.

Physical examination showed that the patient was in shock, but alert and responsive. There was dullness with decreased breath sounds at the right base, and the ninth, tenth and eleventh ribs in the right midaxillary line were tender. The heart sounds were feeble and rapid. The right upper quadrant was tender but nonspastic. There was slight tenderness in both lower quadrants. The liver edge was tender but not displaced below the right costal margin.

The blood pressure was 40/30, the pulse 125, and the respirations 50.

The patient was given 1500 cc. of 5 per cent glucose in physiologic saline solution, 500 cc. of whole blood and 2 units of plasma; the blood pressure rose to 110/80 1 hour after admission. Gas-gangrene and tetanus antitoxin was also given prophylactically. X-ray examination of the chest and abdomen was negative for pneumoperitoneum, pneumothorax and hemothorax. The red-cell count was 3,500,000, with a hemoglobin of 7.5 gm. and a white-cell count of 25,000. The urine was normal. Abdominal exploration was decided upon, the preoperative diagnosis being rupture of the liver.

Under spinal anesthesia the peritoneal cavity was entered, and at least 1500 cc. of free blood was aspirated. A large, 10-cm., stellate-shaped laceration was found on the dome of the right lobe of the liver. The lacerated liver was packed with two squares of gelfoam and three strips of oxycel, and hemostasis was obtained. Two drains were placed in the peritoneal cavity, one in the subhepatic and the other in the suprahepatic space. The abdomen was closed in layers with No. 1 chromic catgut and No. 28 steel-wire stay sutures.

The patient was placed on gastric suction for 3 days. An x-ray film of the chest on the 4th postoperative day revealed fluid in the lower right pleural cavity. On the 5th postoperative day the drains were removed, and he was allowed out of bed. The right side of the chest was tapped, and 1000 cc. of serosanguineous fluid was obtained on the 15th postoperative day. A repeated chest tap 4 days later yielded 150 cc. of foul-smelling pus, from which a hemolytic *Staphylococcus aureus* and *Proteus vulgaris* were cultured.

A diagnosis of subphrenic abscess was made, and on the seventeenth day a thoracotomy was performed, 200 cc. of pus being evacuated from the right subphrenic space. Culture of the thoracotomy fluid revealed *Pseudomonas aeruginosa* and enterococci. The thoracotomy drain was removed 1 week later. The patient received penicillin for approximately 1½ months and was discharged 50 days after admission with a slight amount of purulent drainage from the chest wound.

**CASE 2 (BCH 1267897)** B M, a 26-year-old man, was admitted to the hospital on November 25, 1947, with a history of having been struck by an automobile and dragged approximately 50 feet. He complained of moderately severe right-sided chest pain. This pain was aggravated by deep breathing and was relieved when the patient lay on the right side.

Physical examination showed a conscious and co-operative man who was in shock. There was decreased expansion of the right lung, but the lung fields were clear to percussion and auscultation. The heart sounds were distant and thready. Both upper abdominal quadrants were tender, but there was no muscle spasm. Intestinal peristalsis was audible.

The blood pressure was 60/0, the radial pulse was absent, and the respirations were 36.

X-ray examination revealed no pneumothorax, hemothorax or pneumoperitoneum. Examination of the blood disclosed a red-cell count of 4,010,000, with a hemoglobin of 13.5 gm., and a white-cell count of 20,000. The urine was normal. Plasma, whole blood and gas-gangrene and tetanus antitoxin were given. The blood pressure rose to 100/60. The preoperative diagnosis was rupture of the liver. Abdominal exploration was decided upon.

An upper right-rectus-muscle-splitting incision was made in the abdomen under spinal anesthesia, and whole blood was transfused into the veins of an arm and leg simultaneously. The peritoneum was opened, and about 2 liters of free blood was found in the peritoneal cavity and aspirated. Large jagged lacerations were found in the domes of the right and left lobes of the liver. Oxycel gauze was packed into these lacerations and sutured loosely to the liver with No. 0 chromic catgut. The abdominal wall was closed in layers with No. 1 chromic catgut and four silk stay sutures without drainage.

The patient remained on intestinal suction for 5 days and was sustained on 3000 cc. of fluids administered intravenously

each day. The patient was able to walk on the 2nd postoperative day. X-ray examination showed some haziness present in the left-lower-lung field on the day after operation, but this rapidly cleared by the 10th day. All sutures were removed on the 11th postoperative day. The patient received penicillin intramuscularly for 12 days and was discharged as improved 15 days after admission.

**CASE 3 (BCH 1276872)** N S, a 27-year-old Negress, was admitted to the hospital on February 27, 1948, after having been struck by an automobile. The patient was in shock and complained of severe constant pains in the right shoulder, right lateral portion of the chest and right upper quadrant. These pains were aggravated by breathing.

Physical examination showed the patient to be alert, oriented and co-operative but apprehensive. The skin was cold, clammy and ashen gray. There was splinting of the right side of the chest. The right leaf of the diaphragm was elevated, and the right tenth, eleventh and twelfth ribs in the midaxillary line were tender. The chest revealed no pneumothorax or hemothorax. The heart sounds were weak and rapid. The liver edge was felt 2 fingerbreadths below the right costal margin and was very tender. There was marked tenderness in the right upper quadrant with bilateral rectus-muscle spasm. Intestinal peristalsis was absent. At the junction of the middle and upper thirds of the right leg there was a bony deformity with crepitation, indicating a fracture site.

The blood pressure was 60/40, the pulse 120 to 150, and the respirations 50.

Examination of the blood disclosed a red-cell count of 3,470,000, with a hemoglobin of 10.5 gm., and a white-cell count of 22,150. A specimen of urine was negative for blood.

The patient was given 1500 cc. of 5 per cent glucose in physiologic saline solution, 300 cc. of plasma and 300 cc. of whole blood. The blood pressure rose to 110/70, and the pulse dropped to 112. The right lower quadrant was tapped with a spinal needle, and free blood was obtained from the peritoneal cavity. Because of the patient's response to shock therapy 7 hours after admission, abdominal exploration was decided upon, the preoperative diagnosis being rupture of the liver and questionable rupture of a hollow viscus.

Under spinal anesthesia, while blood was being transfused into one arm and leg, an upper-right-rectus-muscle-splitting incision was made in the abdomen. When the peritoneum was incised, about 1 liter of blood poured out from the peritoneal cavity. The blood was sucked out from the liver and a 12.7-cm. stellate laceration was palpated on the dome of the right lobe of the liver. The stellate laceration was sponged out with dry gauze and packed with four strips of oxycel gauze and held with moderate pressure until hemostasis occurred. The liver capsule was subsequently sutured to the inferior surface of the diaphragm and a portion of the anterior abdominal wall to prevent a suction effect of the diaphragm on the liver. The abdomen was closed without drainage, No. 1 chromic catgut being used as suture material and No. 28 steel wire for stays.

On the third postoperative day the fractured right lower leg was reduced under spinal anesthesia and set in a mid-thigh-to-toes plaster cast. On the 5th postoperative day chest films revealed development of fluid in the right-lower-lung field. The skin sutures and steel stays were removed on the 8th and 11th days after operation. The right side of the chest was tapped on the 26th postoperative day, and serous fluid obtained. Culture of this fluid was negative. Repeated check of x-ray films of the chest revealed clearing of the fluid in the right base. Two months after operation, the cast on the right leg was removed, and a brace applied. The patient received penicillin intramuscularly for 6½ weeks and was ambulatory after the 11th postoperative day. She was discharged 67 days after admission as improved.

## DISCUSSION

The use of absorbable hemostatics in liver surgery is a new procedure. Very little is known of their application to human beings, since most of the literature deals with their use in animals. The cases presented above may be of significance in

It is the consensus of those working in this field that in only a small group of patients are quantitative tests of pulmonary function, particularly divided functions, necessary, but that in the borderline cases they are of tremendous practical help.

Cournand and Richards<sup>19</sup> have reviewed the subject of pulmonary insufficiency and adapted many of the previous laboratory studies to the purposes of clinical medicine. Drawing on their own experience and that of others, they have distinguished between the ventilatory and respiratory aspects of pulmonary function with symptoms of dyspnea and cyanosis respectively. Dyspnea is usually dependent upon a mechanical fault, which in turn may result in a physicochemical imbalance. The two factors may be combined, and they may or may not have cardiocirculatory complications. In the study of ventilatory insufficiency, Cournand and Richards have recommended the following maximum breathing capacity, — that is, maximum voluntary ventilation per unit of time (normally, 154 liters per minute for male and 100 liters per minute for female patients), breathing requirement, and breathing reserve, which equals maximum breathing capacity minus the actual ventilation per minute in any given physical state. The authors have considered the ratio of breathing reserve to maximum breathing capacity a useful index of pulmonary function that could be correlated with observed dyspnea in their cases. Their own experience and that of others suggested that a decrease in arterial oxygen saturation and a decrease in the rate of oxygen removal from the inspired air (ventilatory equivalent) were the most useful indicators of respiratory insufficiency. In a group of 31 thoracoplasty patients, it was apparent that by far the greater part of the subject's loss of pulmonary function existed prior to operation. Of some practical interest was the fact that when the reserve was less than 85 per cent of maximum breathing capacity, a difficult postoperative course was likely. In a review of the published experience of many authors,<sup>20-23</sup> it is apparent that maximum breathing capacity

is the clinical cornerstone of external spirometric methods, replacing the time-honored but

unreliable vital capacity, bronchspirometry, or internal spirometry, has had extensive clinical application, chiefly in the field of collapse therapy.<sup>24-26</sup> Here, the limitations imposed by "stenosis breathing" have

rendered interpretation of results difficult. Norris, Long and Oppenheimer<sup>26</sup> have recently attempted to minimize this factor by using a single-lumen endobronchial catheter to replace the double-lumen catheter of Zavod<sup>27</sup> or Gebauer,<sup>28</sup> which, in turn, replaced the bronchoscopic method of Jacobaeus. The differential uptake of oxygen, usually in conjunction with the ventilatory function of each lung has been the basis of most studies. The analogy

to split renal-function studies is obvious, but the validity of interpretation is not so clear.

Vaccarezza et al<sup>29</sup> have recently described 15 cases of marked discrepancy between clinicoradiologic and bronchspirometric findings. The difficulties of determining function on the basis of the x-ray film are obvious, but it is of interest that the authors accept the laboratory data as their frame of reference when it is apparent, on review of the protocols submitted, that artifacts, particularly those arising from bronchial secretions blocking the airway, may have greatly modified results. In so complex a function as respiration, quantitative measurements must be interpreted with caution. Wright and Woodruff<sup>30</sup> have discussed the complexities of bronchspirometry and have demonstrated many of the variables involved in its clinical application. Wright<sup>31</sup> has recently reported a case of chronic tuberculous empyema in which, after decortication and expansion of the lung, there was only slight increase in ventilation of that lung, and the development of incomplete arterial oxygen saturation. This case is of interest as a qualitative measure of physiologic loss to offset a radiologic gain.

Pulmonary edema has been the subject of a monograph by Drinker,<sup>32</sup> who defends the thesis that pulmonary edema and related phenomena depend more upon alterations and permeability of lung capillaries than upon complicated pressure relations in the pulmonary circulation. Anoxia a cause of increased capillary permeability throughout the body, is considered to be equally effective in the lungs, but the capillary membrane is dependent upon the oxygen of the alveolar air rather than upon that in the blood stream. By blocking the alveoli, "anoxia begets anoxia" as, in shallow breathing, anoxemia, by depressing the respiratory center, leads to further anoxemia.

Eaton<sup>33</sup> has approached the problem of pulmonary edema consequent upon acute blood loss. He had noted an increase in pulmonary lymph flow and histologic evidence of edema in dogs suffering acute loss of 25 per cent of blood volume from the femoral artery. Experimentally, a disproportionate rise of pulmonary-artery pressure seemed to be a significant change in a cycle of progressive circulatory imbalance, which included low systemic arterial pressure and elevated peripheral venous pressure. This fact was interpreted as evidence of an obstruction to normal circulation existing in the lung or the left side of the heart, or both. From this point of departure, efforts were made to measure "pulmonary moisture" under experimental conditions of hemorrhage and replacement. It became obvious that replacement by intravenous saline solution of blood lost led to more consistent and greater increases in "pulmonary moisture" than did replacement by blood. The clinical application of this is apparent.

## MEDICAL PROGRESS

### THORACIC SURGERY

J GORDON SCANNELL, M D \*

BOSTON

THIS report concerns the following aspects of advances in thoracic surgery anatomy of the lung, physiologic considerations, chest injuries, cancer of the lung, tuberculosis, coccidioidomycosis, suppurative disease, bronchiectasis, the esophagus, congenital atresia, and miscellaneous considerations

#### ANATOMY OF THE LUNG

In recent years, significant progress has been made in precise descriptive anatomy of the lung. Advances have been made along two broad lines: accurate topographic description of the bronchopulmonary segment, and reduction of the complexities of bronchovascular anatomy to a reasonable schedule.

Although there is quite general agreement among anatomists and surgeons regarding the disposition of the segments, there is less agreement about their terminology. Boyden,<sup>1</sup> has accepted the nomenclature of Jackson and Huber<sup>2</sup> as the most accurate and simplified currently available. This terminology is based upon the position of the segment within the lobe, rather than upon its relation to the chest wall or adjacent structures. British authors—Brock,<sup>3</sup> Foster-Carter,<sup>4</sup> Appleton<sup>5</sup> and others—have inclined toward the latter view. Brock has published an extremely useful volume on the anatomy of the bronchial tree, which, together with the papers of Jackson and Huber (1943), and Boyden (1945), covers the subject admirably. Boyden<sup>6-10</sup> has also embarked upon a thorough quantitative study of bronchial variations and related bronchovascular patterns.

By way of summary the following schedule of the bronchopulmonary segments is appended, Huber's terminology, Boyden's system of enumeration and, parenthetically, Brock's nomenclature being used.

#### Right Upper Lobe

- 1 Apical (*apical*)
- 2 Anterior (*pectoral*)
- 3 Posterior (*subapical*)

#### Right Middle Lobe

- 4 Lateral (*lateral*)
- 5 Medial (*medial*)

#### Left Upper Lobe

- 1 + 3 Apical-posterior  
(*apical-subapical*)
- 2 Anterior (*pectoral*)
- 4 Superior lingular
- 5 Inferior lingular

#### Right Lower Lobe

- 6 Superior (*apical*)
- 7 Medial basal (*cardiac*)
- 8 Anterior basal (*anterior basal*)
- 9 Lateral basal (*middle basal*)
- 10 Posterior basal (*posterior basal*)

#### Left Lower Lobe

- 6 Superior (*apical*)
- 7 + 8 Anteromedial  
basal (*anterior basal*)
- 9 Lateral basal (*middle basal*)
- 10 Posterior basal (*posterior basal*)

As technical experience with excision of the lung has increased, the need for precise knowledge of the associated vascular arrangement within the lung has become apparent. The surgical contributions of Churchill and Belsey,<sup>11</sup> Kent and Blades<sup>12</sup> and Miskall and Cornell<sup>14</sup> are well known. Recently, Overholt<sup>15</sup> has discussed the subject in surgical detail relative to segmental resection. Regarding bronchovascular anatomy, the studies of Boyden and his associates<sup>6-7</sup> and also of Appleton<sup>16</sup> are of great importance. Complex by necessity, they are available reference material for future clinical developments. In Boyden's work the prevailing bronchovascular pattern and common variations therefrom are discussed in detail and suitably illustrated. The segmental nature of the pulmonary arterial supply, corresponding in general to the bronchial segments, but with considerable variation at the level of the hilus, has been confirmed. The veins, on the other hand, have been shown to be intersegmental. The major clinical application of these studies has been in the technics of segmental resection.

Liebow et al.<sup>17</sup> have reported an excellent and relatively simple method of preparing lungs by the injection of various colored plastics. Particularly in the study of abnormalities of bronchial-artery supply, as well as the production of exquisite anatomic specimens, the method should be of great value. Cauldwell and his associates<sup>18</sup> have described the complexities of the bronchial-artery supply on the basis of 150 cadaver dissections. There is obviously a rich collateral circulation at the level of the lobar bronchus, and great variation in both origin and distribution of the main bronchial-artery trunks.

#### PHYSIOLOGIC CONSIDERATIONS

The measurement of pulmonary function, either total or of each lung separately, continues to have its greatest clinical application in collapse therapy.

\*Instructor in surgery Harvard Medical School assistant in surgery Massachusetts General Hospital

and partial obstruction of the airway. They have postulated a somatovisceral reflex, accounting, in part at least, for changes in the underlying lung following painful injuries to the chest wall. Experimental support is found in the work of deTakats et al,<sup>46</sup> who noted, in the dog, bronchial spasm and increased bronchosecretory activity after trauma to the chest wall, as well as after experimental pulmonary embolization and intra-abdominal manipulation. Daniel and Cate<sup>47</sup> have produced "wet lung" in anesthetized dogs by blunt trauma and tangential bullet wounds of the thoracic cage. Effects of this trauma could be intensified by intravenous infusions of saline, which also produced "wet lung" in dogs breathing low concentrations of oxygen. The effects of excision of large portions of the pulmonary sympathetic supply upon the development of generalized "wetness" were not conclusive, but suggested that the condition was, in part, a reflex phenomenon. Interference with respiratory motion and decrease in effective cough have seemed to many to offer adequate explanation of the pulmonary moisture and collapse following thoracic injury, and reason enough to employ intercostal block in their relief.

To render oxygen administration effective, Army technical bulletins<sup>48</sup> have been explicit in recommending the free and prompt use of tracheal suction or bronchoscopic aspiration. Samson and Brewer<sup>49</sup> have recently reviewed their experiences in this regard and outlined practical suggestions to improve inadequate tracheal-bronchial drainage following trauma to the chest. The technics of tracheal aspiration and the importance of forced cough after the airways have been cleared are carefully explained.

One of the definite departures from prewar practice has been in the treatment of hemothorax. On the theoretical ground of controlling continuing bleeding from a lacerated lung, aspiration of blood with air replacement had been recommended. During the war, however, it was found that continuing intrapleural hemorrhage was rarely of pulmonary origin, that prompt re-expansion of the lung was desirable and that prompt needle aspiration of massive hemothorax, the blood obtained being used for autotransfusion if necessary, should be carried out. The use of whole blood in chest wounds, when it is of obvious importance to restore the oxygen-carrying capacity, as well as the volume of circulating blood, was established.

The late effects of intrapleural bleeding with clotted hemothorax or chronic hematoma of the pleural space were responsible for one of the more dramatic surgical developments of the war—namely, pulmonary decortication. Samson and Burford<sup>50</sup> have presented an excellent general review of the subject and have given a detailed account of the technic of operation. They have emphasized the fact that the fundamental lesion

is not of the pleura itself but of a false membrane overlying the pleura. The aim of the procedure is early restitution of pulmonary function, and the avoidance of the late, crippling effect of extensive fibrothorax. They, in common with most authors who have written on this subject, limit their procedure chiefly to the visceral pleura and are not concerned with the parietal peel. In the uninfected clotted hemothorax, decortication was carried out four to six weeks after trauma if there appeared, by x-ray examination, to be lateral pulmonary compression of 50 per cent or more, if there were obvious limitations of chest expansion and if there was clinically significant shortness of breath. It was believed that prior to three weeks after injury, the peel was not sufficiently tough to permit satisfactory removal, and that after that time fibrous changes were found in the lung. In cases of infected hemothorax, the time of operation was advanced to about two weeks after trauma. Signs of increasing toxicity, mounting fever or rapid increase in the size of the hemothorax were considered presumptive evidence of infection. In 125 cases in which operation was performed, there were no deaths and no serious sepsis, and less than 25 per cent of patients had residual empyemas, the great majority of which were small and basal in location. The authors estimated that approximately 1500 early decortications had been done in the armed forces with an operative mortality of less than 2 per cent.

Tuttle, Langston and Crowley<sup>51</sup> have also reported essentially similar experiences with early decortication for chronic traumatic hemothorax and have described in detail the pathological changes encountered in this condition. Of 89 cases of uninfected (not grossly infected), and 51 grossly infected hemothoraces, a total of 140 cases, the results were good in 77.1 per cent, fair in 18.6 per cent and poor in 4.3 per cent, there were no deaths. Their criterion for "good" was exacting—namely, that the lung after the operative procedure expanded completely in forty-eight hours. A "fair" result meant that the ultimate result was good, but somewhat delayed. In the cases of infected organizing hemothorax (51 cases), primary healing of the empyema occurred in 49.1 per cent, eventual healing in 45.1 per cent and chronic empyema in 5.8 per cent. Penicillin was not always available during the course of this study and was used in 77 of the 140 patients. It is of interest that all 25 patients who experienced primary closure of the empyema space after decortication received penicillin. Sanger<sup>52</sup> has argued that perhaps the importance of penicillin has been overrated in decortication for empyema, admitting, however, that it has given the surgeon courage to proceed in the presence of severe infection. He believed that the mechanical removal of the culture medium upon which the organisms could grow and the re-expansion of the

Collateral ventilation has been restudied by Baarsma and Dirken<sup>34</sup> spirometrically, confirming, in rabbits, the previous work of Van Allen and his associates in dogs. The Dutch authors have also extended their studies to man.<sup>35</sup> In a limited series of observations, using an occluding catheter with an inflatable cuff, no collateral ventilation was apparent on occlusion of a lobar bronchus, but definite collateral ventilation was demonstrated upon occlusion of a segmental bronchus in the lower lobe. Lindskog (who contributed much to the early studies in this field) and Alley<sup>36</sup> have recently observed in dogs that the intravenous administration of histamine results in the abrupt cessation of collateral respiration that persists for variable periods of minutes. This effect is abolished by prior administration of benadryl. It seems important to extend these observations to other agents in common clinical use and to changes in the physiologic state of the patient.

Perhaps the physiologic advances that have the greatest bearing on thoracic surgery have been consequent upon the recent development of the cardiac-catheterization technic. First introduced by Forssman in 1929, much of its recent development is attributable to the efforts of Courmand and his associates.<sup>37</sup> Furthermore, effective teamwork between physiologist and surgeon has been particularly apparent in the combined efforts of Bing et al.<sup>38</sup> on the one hand and Blalock and his co-workers on the other. McMichael,<sup>39</sup> in Great Britain, and Dexter and his associates,<sup>40</sup> in Boston, have also contributed significantly to the subject. The use of the method is by no means limited to these few centers, and the literature on the subject is extensive.

The earliest of recent efforts were directed toward accurate measurement of cardiac output utilizing the Fick principle, which, stated simply, is that cardiac output equals oxygen intake divided by arteriovenous oxygen difference. Heretofore, inaccuracies had arisen from the inability to obtain true mixed venous blood. By sampling directly from the auricle, the ventricle or the pulmonary artery this source of inaccuracy could be obviated.<sup>37</sup> By further development of the Fick principle, direction and amount of flow in abnormal circulatory shunts could be estimated.<sup>38-40</sup> By study of pressure changes in the ventricles, pulmonary arteries, peripheral arteries and other portions of the circulatory system, more accurate study of hemodynamics is now possible, and precision methods of the experimental laboratory can be applied to clinical problems. Changes in the pulmonary circulation under physiologic and pathologic conditions are at present under the closest scrutiny.<sup>38-40-41-43</sup>

Although cardiac catheterization has been a relatively safe procedure, there are hazards attendant upon its use. Cardiac irregularities during catheterization are not uncommon, there is always

the hazard of air embolism in the presence of a right to left shunt, and intimal damage though presumably rare, remains a possibility. However with proper indications, there can be little doubt of the clinical and experimental value of the method.

### CHEST INJURIES

In the war the principles underlying the management of serious injuries to the chest were tested against a tremendous volume of experience. Many concepts, proved valid after much extensive trial, are directly applicable to the severe chest injuries encountered in civilian practice and in the casualties of heavy industry and high-velocity automobiles.

Churchill<sup>44</sup> has presented, in general terms, the management of thoracic casualties in the military theater to which he was consultant. He has emphasized the importance of distinguishing two phases of chest trauma: the serious disturbance of cardio-respiratory physiology that demands prompt and intelligent treatment, and the problem of infection, which requires fully as intelligent but less urgent attention. More specifically, he suggests, "the urgent physiologic disturbances that attend wounds of the chest can be controlled by needle aspiration of air and blood, aspiration of blood and mucus from the tracheobronchial tree, novocaine injection of intercostal spaces, insertion of a catheter with a flutter valve for pressure pneumothorax, oxygen therapy and transfusions, and débridement of sucking wounds with hemostasis of intercostal vessels and approximation of deep structures of the chest wall to close the pleural opening." In the emergency treatment of such wounds, however, an occlusive dressing of petrolatum gauze and adhesive strapping was not only adequate but also preferable to an airtight closure in that it could act as an escape valve in case a persistent bronchial leak were present.

Of the measures detailed above, some have important application to trauma as seen in civilian life. Significant among these is the use of intercostal block for the relief of pain, as opposed to the time-honored but physiologically unsound, overgenerous use of morphine and tight adhesive strapping. The latter should be reserved for minor rib fractures, and possibly also for a few cases of paradoxical motion of the chest wall resulting from anterior and posterior fractures of the ribs. In such cases, when the paradoxical motion is of an intolerable degree, open operation may be necessary. By permitting the patient to cough effectively and breathe actively, intercostal block is instrumental in maintaining a clear airway so essential to the patient. Some authors, notably Burford and Burbank,<sup>45</sup> on the basis of considerable first-hand experience with thoracic casualties, have argued that the "wet lung of trauma" may depend on more than mechanical interference with the chest bellows.

histology of fragments in the sputum, with careful study of the characteristics of the individual cells.

More recently, there has been widespread interest in the cytologic study of sputum by the Papanicolaou technic or its modifications. At the recent Quebec meeting of thoracic surgeons, Watson et al.<sup>66</sup> reported their experience in the study of pulmonary neoplastic disease. In 400 cases studied at The Memorial Hospital, 236 patients had carcinoma, and of these, 141 (60 per cent) had positive sputums. False-positive reactions occurred in 4 of an over-all group of 1200 cases. In 3 cases the specimen came from a patient subsequently found to have bronchiectasis, and the confusing cells were probably fragments of papillomatous growths of the bronchial mucosa such as have been previously described.

In 1946 Herbut and Clerf<sup>67</sup> reported 83 cases studied, in which 38 patients had carcinoma — 30 with positive sputums, or 79 per cent positive reactions. No false-positive tests were reported. These authors stressed the desirability of studying bronchial washings obtained at time of bronchoscopy by saline irrigation and aspiration of specific limbs of the bronchial tree, rather than sputum, which is more dilute and whose source is less specific. A preliminary survey of the experience with pulmonary cases at the Massachusetts General Hospital yields the following figures.<sup>68</sup> In a total of 157 cases studied in 1946, 56 patients were shown to have carcinoma of the lung. One hundred and nineteen had sputum studies, with false-negative reactions in 37.9 per cent and false-positive reactions in 6.0 per cent. In 81 cases cytologic examination of bronchial washings was performed, with 56 per cent false-negative and 1.8 per cent false-positive tests. In the following year, 123 cases were studied with either or both methods. Fifty-four patients had cancer. Examinations of the sputum were performed in 74 cases, with 25.7 per cent false-negative and no false-positive reactions. In 60 cases of bronchial aspiration there were false-negative tests in 66.0 per cent and no false-positive tests. Strieder<sup>69</sup> reports the experience at the Boston City and the Massachusetts Memorial Hospitals, as follows: in 170 cases studied bronchoscopically, 48 patients had carcinoma proved histologically, and 6 had unequivocal clinical evidence of carcinoma. Positive smears were obtained in 40, or 74 per cent of the 54 cases. False-positive reactions occurred in 3 cases, or 1.8 per cent. Bronchoscopy was positive in 29 of the 54 cases, or 54 per cent.

A review of the reported experience at large makes it apparent that theoretically and in practice, cytologic examination of the sputum will give a higher percentage of positive results than bronchoscopic biopsy. Added to the other data obtained in a given case, it may be an important bit of evidence, when positive, on which the decision to operate may be based. Particularly in the early and ob-

scure case, it may be of great value in strengthening the surgeon's hand. It is also apparent that the incidence of false-negative reactions is sufficiently high so that a negative examination cannot be strongly considered in ruling out carcinoma — 18 per cent in Wandall's<sup>65</sup> series, 43 per cent in that of Gower,<sup>64</sup> 21 per cent in that of Herbut and Clerf,<sup>67</sup> 36 per cent in that of Graham,<sup>68</sup> 40 per cent in that of Watson et al.,<sup>66</sup> and 26 per cent in that of Strieder.<sup>69</sup>

Other than the introduction of cytologic methods, little has been added to the diagnostic devices of the expert consultant in carcinoma of the lung. The value of bronchoscopy is well known, but Churchill's<sup>62</sup> statement should be emphasized:

The purpose of bronchoscopy extends beyond the removal of a fragment of tissue to confirm the histologic diagnosis. Unless the examination is carried out by an operator who is accustomed to make his observations in terms of the feasibility of a surgical attack on the lesion, the bronchoscopy may have to be repeated by one who is

Bronchography is rarely indicated in diagnosis of cancer of the lung, and except under unusual circumstances may complicate further x-ray studies and clinical management of the case. It should be emphasized that x-ray study implies a real responsibility of the roentgenologist in assisting in the management of the patient, and not merely the routine chest film. Were it not for the great number of cases in which the observation is not made until late, it would seem superfluous to recall the importance of a careful palpation of the neck for metastases to lymph nodes. Simple biopsy of these may not only lead to the diagnosis but also determine the whole plan of management and save the patient prolonged hospitalization, often at considerable distance from home.

In summarizing the problem of early diagnosis and the management of the patient, Churchill<sup>62</sup> writes as follows:

This review of the responsibilities of the expert consultant makes it obvious that he should have at his command a number of diagnostic techniques that range from careful case history taking and physical examination, to thoracotomy for biopsy of a doubtful lesion. These responsibilities must be faced in logical sequence and carried through without delay. On the other hand, the consultant may indulge in certain assumptions relative to his responsibility that are not altogether warranted. Attention is called to these because they may retard the development of that close relationship between practitioner and specialist that is desired to promote progress in cancer control. They also directly influence the extent to which the patient will respond to the educational efforts that urge him to consult a physician in regard to early symptoms.

One of these assumptions is that the expert must invariably exclude any possibility of cancer, however remote, by resorting to major diagnostic techniques without regard to whether the clinical problem under consideration indicates their use. Another false assumption is that a presumptive clinical diagnosis always must be extended to histological confirmation despite the fact that the course of management is obviously not going to be altered by the reading of the microscopic slides. Finally, in deciding on the course that the management of an advanced case is to take, surgical exploration is oftentimes proposed as the

incarcerated lung were of more importance than chemotherapy, which, however, seemed to be of greatest effect in preventing invasive infection. As a result it now appears not only possible but also, in many cases, advisable to convert a localizing empyema into a generalized pleural contamination to re-expand the lung, thereby reversing the field completely so far as the classic treatment of empyema is concerned.

One of the casualties of the war has been the sanctity of the diaphragmatic barrier. For many years the transthoracic route to the structures of the upper abdomen has been employed, but not with the zeal and general enthusiasm that is now apparent.<sup>53</sup> It seems reasonable to suppose that the wide experience with thoracoabdominal wounds in the recent conflict has done much to break down the old pattern of thought, which divided the body neatly at the midriff. Space does not permit a review of the many excellent reports of experience in large thoracic centers and general hospitals in the Army and Navy.<sup>54-60</sup> In a sense, these reports are the source material from which broader concepts of the management of serious thoracic injury have been derived.

Blades<sup>61</sup> has recently summarized the opinion of many others that the advances in the treatment of chest injuries during the war were largely the result of judicious timing and selection of surgical procedure rather than technical improvement. In summary of the application to civilian emergencies of lessons learned from the military, he has emphasized the use of whole blood in the treatment of shock, the dangers of excessive use of morphine, the control of chest pain by paravertebral block, the treatment of "traumatic wet lung" by paravertebral block, oxygen and tracheobronchial aspiration, the early aspiration of hemothorax to effect complete re-expansion of the lung and conservation of cardiopulmonary function, and, finally, decortication in cases of clotted hemothorax based on indications established in the war.

## CANCER OF THE LUNG

### *Earlier Diagnosis*

Churchill<sup>62</sup> has recently reviewed the problem of cancer of the lung and re-emphasized the need of earlier diagnosis, pointing out that it is doubtful if more radical treatment can be devised that will materially improve results. The limits of operability — so far as the patient's chance of surviving major surgery are concerned — have been extended, so that resectability rates are steadily being revised upward. It is important to remember, however, that the rates are a measure not only of the individual courage and skill of the operator but also of the process of selection of cases before the patient reaches the surgeon. There is therefore

great need for intelligent teamwork between practitioner and expert consultant.

For various reasons, detection by means of survey films shows only moderate promise. Men between forty and sixty, the age group that suffers the highest incidence of pulmonary cancer, are the most difficult to include in any survey. Furthermore, except for the few silent peripheral lesions, x-ray changes are usually dependent upon bronchial encroachment, which produces symptoms sufficient to send the patient to the doctor.

The symptoms of cancer of the lung are well known and need no repetition here, except to recall that they may be so commonplace as to escape the serious attention of the patient or his physician. As many have emphasized, the important points in a review of symptoms are change in cough habits, persistent, unexplained or rationalized x-ray shadow, persistent streaking of the sputum — corresponding to the constant trickle from a gastrointestinal cancer that gives rise to occult blood in the stool, and the cold that "hangs on."

One of the more important recent advances in the diagnosis of cancer of the lung has been the increasing use of cytologic studies of the sputum or of bronchial secretions. Many papers dealing with the technics of such studies are available. As in any precise laboratory maneuver, great attention must be paid to the details of collecting and preparing the material, and considerable mature judgment must be exercised in interpretation of specimens. Although examination of the sputum for tumor cells had been done sporadically for many years, the first widespread and successful clinical application of the method was reported by Dudgeon and Wrigley<sup>63</sup> in 1935. They found 43 positive sputums in 56 cases of proved carcinoma of the lung — that is, false-negative tests in 23 per cent of their cases. In 2 of 102 cases the sputum was reported positive, but these cases were ultimately proved to be of inflammatory nature — false-positive reactions, therefore, in 2 per cent of cases. In 1943 Gower,<sup>64</sup> at the London Hospital, reported a series of 93 patients suffering from pulmonary disease of whom 63 were proved to have carcinoma. Of these, 36 (57 per cent) had a positive sputum — false-negative reactions, therefore, in 43 per cent. The number of false-positive tests was not stated. Wandall, in 1944,<sup>65</sup> reported extensive experience culled from the hospitals of Copenhagen. One hundred and ninety-three patients with pulmonary disease were studied, 120 of whom were proved to have carcinomas of the respiratory tract, of which 100 were carcinomas of the lung. Of the 120, there were positive sputums in 98 (82 per cent), or 18 per cent false-negative reactions. Of the 193 cases, there were 32 per cent false-positive tests in cases of chronic pneumonia and tuberculosis. Wandall's series and those reported above were based on the

### CASE 34501

#### PRESENTATION OF CASE

*First admission* A thirteen-year-old girl entered the hospital complaining of pain in back of the left knee and in the hips

The symptoms were first noted one and a half years prior to admission, following strenuous activity or occasionally after prolonged sitting in one position. The pain was usually relieved by resting the leg. X-ray films were taken at the time of onset of the pain and were reported as normal. However, repeat films six months later revealed undescribed changes. The patient was then placed in a spica cast for three months, followed by a nonweight-bearing cast for an additional six months. Neither the cast nor the brace effected much change in the symptoms, which continued as before. The pain was not too well localized but seemed to be mostly in the left groin and popliteal space. At first the pain was periodic and related to activity, but later became more or less continuous and was not affected by exercise or relieved by rest. Aspirin usually brought relief, which lasted about four hours. The patient ran a low-grade afternoon fever (temperature of 99.4 to 99.6°F), but there were no chills, night sweats or cough.

The past and family histories were entirely irrelevant.

Physical examination showed a well developed and well nourished girl. Examination was entirely negative except for the left leg and hip. The legs were equal in length, but there was atrophy of the left thigh and calf. The hip was held in 20° permanent flexion. Rotation in extension was about two thirds

normal. Abduction and adduction were very slightly limited. On flexion the hip went into 30°

FIGURE 1

of permanent external rotation and into 20° of abduction at right-angle flexion.

The temperature was 99.8°F, the pulse 90, and the respirations 20. The blood pressure was 110 systolic, 65 diastolic.

Examination of the blood showed a hemoglobin of 14 gm and a white-cell count of 10,900, with 59 per cent neutrophils, 30 per cent lymphocytes, 10 per cent monocytes and 1 per cent eosinophils. The

"only chance" and as such, one that cannot be denied the patient. In their quest for scientific exactitude the members of the profession must not confuse scientific precision with which certain parts of the evidence can be formulated, with the broad responsibility of weighing evidence as a whole. Courts of law may exact severe or even capital punishment if the evidence as a whole is judged valid "beyond any reasonable doubt." It is the responsibility of the consultant in conference with the family medical advisor to determine whether the "only chance" offered by surgical treatment is in truth a reasonable chance, or whether the cancer is surgically "out of bounds" beyond any reasonable doubt.

(To be concluded)

ture, which was not present. Lesions that we should consider seriously are osteoid osteoma and eosinophilic granuloma. I do not believe that I can completely exclude them. Osteoid osteoma causes constant pain such as this, with insidious onset, often worse at night and almost always relieved by aspirin. So from the history that is a possibility. By x-ray examination, it cannot be completely excluded, but the films are certainly not characteristic of osteoid osteoma. There is usually much greater sclerosis of the bone as well as an area of decreased density. With good x-ray technic we can almost always demonstrate a small nidus in the center, which I do not see. Do you see it, Dr. McCort?

DR. MCCORT: No, I certainly do not see it.

DR. BARR: If a central nidus is not present, I think it is unlikely to be osteoid osteoma. I have not seen such a lesion without a nidus.

I have seen a few cases of eosinophilic granuloma but have never made that diagnosis preoperatively. I think this could have been an eosinophilic granuloma. The pain was consistent. There is usually a bone-destroying lesion, and that is about as much as I can say about it.

The mechanical things that we usually consider I think can be ruled out. We have a lesion within the neck of the femur, and I think we can rule out slipped epiphysis and Legg's disease and so forth. We then come definitely to infection, and the picture does fit an infectious process. The patient had continuous pain, possibly an elevation in temperature, rather continuously, and a little change in differential count and in the monocyctic and lymphocytic ratio. Bone infections can go on for months or years with very little change in the appearance of the bone. If so, this obviously was a low-grade infection, and we have to consider the two main groups — a Brodie abscess or tuberculous infection of bone. I do not see how one can differentiate satisfactorily. A Brodie abscess usually produces more sclerosis than this, but I have seen *Staphylococcus aureus* infection of bone with practically no bone reaction about it, having been present a long time. Nevertheless, I lean a little toward tuberculosis. The tuberculin test was positive, and there was a very slowly progressive lesion in the central portion of the neck of the femur. I shall make a diagnosis of a low-grade infectious process, possibly tuberculosis.

DR. MARIAN ROPES: When I saw the patient before operation I had no idea what she had. I thought of the possibilities that Dr. Barr has mentioned, I did think she had definitely a synovitis and believed that the physical findings were consistent with that. I thought then and even at operation, when the synovial tissue in the hip was involved, that she had hemorrhagic villonodular synovitis with extension into the bone, although it was different from the average case that has been seen here at least. Beyond that I had no idea.

## CLINICAL DIAGNOSIS

Osteoid osteoma?  
Tuberculosis?  
Villonodular synovitis?

## DR. BARR'S DIAGNOSIS

Low-grade infectious process, possibly tuberculosis

## ANATOMICAL DIAGNOSES

*Osteoid osteoma*  
Acute synovitis

## PATHOLOGICAL DISCUSSION

DR. MALLORY: On the second occasion the hip joint was explored, and besides a diffuse synovitis, with considerable hypertrophy of the synovia, a localized lesion was found in the bone that appeared to penetrate the cortex in one or two spots. This was curetted out, and the material from the operation was divided into two lots, as we usually do with arthritic material, and the portion that we received showed nothing. We then asked the Arthritic Service to give us the other half, in which we found a characteristic osteoid osteoma. This is the first one we have seen in which the lesion had penetrated through the cortex of the bone, they are almost invariably subcortical. This one did not show much increase in density in the surrounding cortical bone which is uncommon.

DR. BARR: What did the synovia show?

DR. MALLORY: Acute and chronic inflammation — there was nothing specific about its appearance at all.

DR. GRANTLEY W. TAYLOR: What were these cases called before they were identified as osteoid osteoma? The patients must have been seen and operated on from time to time.

DR. MALLORY: It seems most probable that they were reported as healing, sclerosing osteomyelitis.

DR. BARR: The evidence for neoplasm is still very uncertain in my mind in these lesions because one rather striking thing is that no matter how long they last they apparently never grow beyond 0.5 to 1.5 cm in diameter. Did you do special stains for nerve fibrils?

DR. MALLORY: No.

DR. ROPES: We wondered what caused the synovitis. It must have been reaction to the material that penetrated from the cortex of the bone into the joint.

## CASE 34502

### PRESENTATION OF CASE

*First admission.* A sixty-one-year-old woman, a schoolteacher, was admitted to the hospital because of nausea and vomiting.

urine was normal. The blood calcium was 9.3 mg, the phosphorus 4.9 mg and the alkaline phosphatase 3.9 units per 100 cc.

X-ray studies of the left hip showed a smoothly rounded area of slightly decreased density, measuring 1 cm in diameter, in the neck of the femur. There was questionable slight bone reaction about the area of decreased density (Fig. 1). Examination of the pelvis, tibiae, fibulae and skull was essentially negative. A tuberculin test was negative when given in 1:100,000 and 1:10,000 dilutions but positive at 1:1000.

The lesion was drilled through a lateral incision with a 0.79-cm drill and some material was curetted. Although it was believed that the drill had entered the lesion, microscopical examination showed only bone spicules. Subsequently the pain was less severe for several weeks but then recurred as before in the left hip and popliteal space. The patient had no other symptoms and was otherwise healthy.

*Second admission.* Five months after discharge she was again admitted for further study. Physical examination showed essentially the same findings as previously.

Examination of the blood showed a hemoglobin of 13.4 gm and a white-cell count of 7200, with 64 per cent neutrophils, 23 per cent lymphocytes and 13 per cent monocytes. X-ray films revealed an oval defect 3 cm in diameter in the neck of the left femur in the area previously described. On the second hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR JOSEPH S. BARR: I assume that the nonweight-bearing cast was actually a brace.

I might point out in passing that "although it was believed that the drill had entered the lesion, microscopical examination showed only bone spicules." Missing a small lesion that they are attempting to explore or to biopsy is an error that all orthopedic surgeons make. Almost all of us want to make certain and take x-ray films in two planes at the time of biopsy, with an instrument or metallic body at the area to assure correct localization.

DR TRACY B. MALLORY: That was done in this case.

DR BARR: Apparently the lesion was missed in spite of that.

May we see the x-ray films?

DR JAMES J. McCORT: This examination was made preoperatively. A small, osteolytic lesion is present in the neck of the femur, measuring 1 cm in diameter. The margins of this lesion show slight irregularity, but there is no sclerosis of the surrounding bone. The lateral view shows it to lie just beneath the anterior cortex of the femoral neck. There is no swelling of the soft tissue over it and no periostitis. Are you interested in seeing the postoperative films?

DR BARR: Yes.

DR McCORT: This is the track made by the instrument at the time of the first biopsy. It appears to lead into the lesion. I cannot definitely identify it in the lateral view.

DR BARR: One can be directly over the lesion in one view and miss it by any distance in the opposite.

DR McCORT: The long bones and skull are normal.

DR BARR: This thirteen-year-old girl had pain in the back of the left knee and in the hip. The onset of symptoms was at the age of eleven and a half years, and the pain was relieved by rest, although finally it became continuous but was somewhat relieved by aspirin. Other points are that the patient apparently ran a very slight fever throughout the course. The legs were equal in length, indicating that the lesion apparently was not near an actively growing epiphysis. If it had been at the epiphysis the length might have been decreased owing to interference with growth. Restriction of motion is interesting in that the leg on flexion went into external rotation and abduction. This finding is most common in slipped upper femoral epiphysis. However, in the slipped upper femoral epiphysis there is usually no permanent flexion but actual increase in hyperextension, and there was permanent flexion deformity in this case. Legg-Calvé-Perthes disease can cause restriction of motion similar to this. There is a rare condition called coxa magna in which the head of the femur is larger than normal and motion is restricted. If restriction of motion is due to muscle spasm, it does not assume this form. The leg may be adducted instead of abducted, and flexion is restricted without external rotation deformity. In addition to the slight elevation of temperature there may possibly have been slight elevation in the white-cell count. The lymphocyte-monocyte ratio was slightly elevated. The tuberculin test was positive, if it had been negative, it might exclude tuberculosis but since it was positive we cannot exclude tuberculosis.

In differential diagnosis I think we can exclude without much further consideration the generalized bone diseases, such as Hand-Schüller-Christian disease, polyostotic fibrous dysplasia and hyperparathyroidism, the skull showed no apparent lesions. The single lesions that we must consider are bone cyst, monostotic fibrous dysplasia, giant-cell tumor, enchondroma, Ewing's sarcoma and Hodgkin's disease, but I think none of them fit the picture very well. If this was a Ewing's sarcoma or Hodgkin's disease, with this duration, the patient should be either not alive or acutely ill, and we would have signs of progression of the process or involvement of the lungs or, in Hodgkin's disease, of the lymph nodes or elsewhere in the body. A bone cyst would not cause such acute symptoms as this patient had unless it had produced a frac-

The temperature was 99°F, and the respirations 20. The blood pressure was 170 systolic, 110 diastolic.

Laboratory data included a hemoglobin of 14.8 gm. The urine gave a ++ test for albumin and the sediment contained occasional granular casts, 10 white cells and a rare red cell per high-power field. A blood sugar determination was 41 mg per 100 cc.

Intravenous glucose was followed by rapid recovery of consciousness. The following day the temperature was elevated to 102°F. She vomited frequently and despite intravenous therapy, died on the second hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. JOSEPH C. AUB: This seems to be such an obvious case that I am certain that the pathologists have it in for me. Obviously, it is a case in which they want a diagnosis of Addison's disease, and I cannot make any other diagnosis.

One can ascribe the trouble in the knee to tuberculosis. If the pathologists diagnosed tuberculous salpingitis, we have to assume that this woman had tuberculosis.

The blood chloride level is recorded as 82 milliequiv, and yet she had a normal blood pressure at that time. I do not understand that.

The intravenous pyelogram in the second admission was negative, that is important, considering the high blood pressure at death.

It should not be forgotten that cases of Addison's disease are often diagnosed as psychoneurosis. If these people do have Addison's disease, psychotherapy does not help much.

The weight loss is important because all patients with Addison's disease lose weight. They do not look thin, but all have a history of loss of weight. This patient had vomiting, of course, which complicates this fact but goes with Addison's disease.

A biopsy of the buccal mucosa would have been helpful, but I am assuming that the patient had a generalized pigmentation.

The excretion rate of 17-ketosteroids is negligible, and this is important as evidence for Addison's disease. The urine sodium of 2.3 gm. does not mean anything. Every well person eats from 2 to 15 gm of sodium chloride a day, and much of this comes out in the urine. Excretion of 2.3 gm in twenty-four hours is not high for a normal person, but it varies with the diet and medication.

It is not unusual in Addison's disease to find an associated low blood sugar, such as this patient had on her final admission, and this is considered an ominous prognostic sign.

The temperature was high for a woman in an Addisonian crisis.

A weak heart goes with Addison's disease, and she may have had too much intravenous salt, dying of cardiac complications.

There are a great many things that I would like to know about this case. I am not going to ask for anything, however. (Your host gives you a certain number of data, and you accept them, I do not ask for more.)

May we see the x-ray films?

DR. STANLEY M. WYMAN: The film of the chest is not of ideal quality. It shows calcification in the right-upper-lung field and, I think, a questionable area of fibrosis in the right apex. The heart shadow is not small, in fact, it appears somewhat prominent toward the left, possibly in the left ventricle. The aorta is quite tortuous.

DR. OLIVER COPE: When was this film taken in relation to death?

DR. WALTER BAUER: About six months before death.

DR. WYMAN: The right knee shows an old fusion as described in the physical examination.

DR. AUB: Can you ascribe a cause to that appearance?

DR. WYMAN: I cannot say. It is just a fused knee.

The gastrointestinal examination shows a small hiatal hernia, the stomach and colon are normal without evidence of defects. I do not see calcification in the region of the adrenal glands.

DR. AUB: Is there anything in the spine?

DR. WYMAN: There is no evidence of active disease.

The kidneys are normal in size and shape. A film twenty minutes after injection of dye shows fairly good excretion. There is no calcification above the kidneys. The skull examination, not mentioned in the protocol, shows rather prominent vascular lakes in the base, I can see no definite evidence of localized disease or chronic increased pressure. The pituitary body is of good size and not abnormal.

DR. AUB: I do not believe there is good evidence for tuberculosis in the lung, is there?

DR. WYMAN: There is no definite active disease.

DR. AUB: I cannot make any diagnosis except Addison's disease. I should like to know what happened to the size of the heart as the disease went on and as the patient got worse. I should like to know what the basal metabolic rate was, and what the diuresis following ingestion of water was. She had orthopnea, nausea and vomiting, hypoglycemia, probable loss of weight, syncopal attacks, pigmentation, a diagnosis of neurasthenia, low blood chloride and a low blood sugar — all these are consistent with Addison's disease. I believe she died in an acute Addisonian crisis, with hypoglycemia. She had been given a good deal of fluid, and she responded very poorly.

The blood pressure was 170 systolic, 110 diastolic, when she came in in an Addisonian crisis. This is most unusual and puzzling. It is possible that the patient's physician gave large doses of desoxycorticosterone acetate and much intravenous therapy.

Ten days previous to admission the patient suddenly developed nausea and vomiting unrelated to food and with no associated pain. In the preceding eight or nine weeks she had been taking two aspirin tablets every three hours because of pain in the left knee. There was no tinnitus or vertigo.

The past history revealed recurrent episodes of arthritis involving the right knee that began at the age of twelve and continued until the age of thirty, when pulmonary tuberculosis was diagnosed. On bed rest she recovered rapidly, and a fusion of the right knee was performed; tubercle bacilli were not isolated from the joint. She had no further pulmonary symptoms and no difficulty with the right knee except that due to its immobility. Ten years before admission, because of severe menorrhagia, a hysterectomy was performed, and a diagnosis of tuberculous salpingitis was made. Her maternal grandmother and two siblings had died of tuberculosis, but the patient was never exposed to the disease.

Physical examination revealed an obese, dehydrated woman with a slightly acidotic breath. The lungs were clear to percussion, with bronchovesicular breathing over the left apex and below the left clavicle. The right knee was fused in slight flexion. The left knee was slightly warm, and there was slight crepitation on motion.

The temperature, pulse and respirations were normal. The blood pressure was 126 systolic, 80 diastolic.

Examination of the blood revealed a hemoglobin of 12.4 gm and a white-cell count of 10,300, with 62 per cent neutrophils. The urine specific gravity was 1.008, and the sediment contained occasional red cells and 4 pus cells per high-power field. The blood chloride was 82 milliequiv per liter, and the nonprotein nitrogen 27 mg per 100 cc. The fasting blood sugar was 87 mg per 100 cc. The sedimentation rate was 40 mm per hour.

An x-ray film of the chest showed fine, linear areas of increased density extending into the apex of the right upper lobe and one small calcified shadow. The film of the left knee showed considerable sharpening of the tibial spines but no joint narrowing or calcification. The right knee was fused. An upper gastrointestinal series was negative.

The patient was given sedatives and infusions were necessary initially, but she was later able to retain oral feedings. She was discharged improved after five days in the hospital.

*Second admission* (seven days later). Anorexia, nausea and occasional vomiting persisted after discharge. She became progressively weaker and was readmitted.

The physical findings were essentially as before.

The temperature was 98.2°F, the pulse 72, and the respirations 20. The blood pressure was 110 systolic, 70 diastolic.

Examination of the blood showed a hemoglobin of 14 gm and a white-cell count of 8200, with 54 per cent neutrophils, 31 per cent lymphocytes, 13 per cent monocytes and 2 per cent eosinophils. A urine specific gravity of 1.012 was demonstrated; the sediment contained rare hyaline casts and rare pus cells. The stools were guaiac negative. The serum amylase was 35 units, the nonprotein nitrogen 35 mg, and the serum protein 5.3 gm per 100 cc; the chloride was 94 milliequiv per liter. A barium enema, cholecystogram and intravenous pyelogram were negative.

Sedatives and later psychotherapy did not control the vomiting. After three weeks in the hospital the blood chemical findings were as follows: sodium 131 milliequiv, chloride 82 milliequiv and potassium 6.1 milliequiv per liter, sugar 97 mg and total protein 5.1 gm per 100 cc.

The patient lost 7 pounds in weight. Pigmentation of the buccal mucosa and of the creases in the palms as well as a generalized "tan" seemed evident to several observers. Six grams of salt daily, 5 mg of desoxycorticosterone acetate daily, and later 2 cc of lipoadrenal extract every six hours caused slight subjective improvement, but the blood chemical values were altered very little. Blood-pressure readings, which averaged 80 systolic, 65 diastolic, were elevated slightly. The vomiting continued but was less frequent, and intravenous fluids were still necessary. Testosterone, 10 mg daily, was added to the therapy. Lipoadrenal extract was omitted. Desoxycorticosterone acetate 10 mg daily for several days, caused little alteration of the serum sodium content. After two months in the hospital the blood chemical values were as follows: sodium 124 milliequiv, chloride 102 milliequiv, and potassium 4.7 milliequiv per liter, and serum protein 4.5 gm per 100 cc. The twenty-four-hour urinary excretion of 17-ketosteroids was 0.7 mg and of sodium chloride 2.3 gm. Omission of desoxycorticosterone acetate caused anorexia, vomiting, diarrhea and loss of weight but little change in blood pressure. An adrenocorticotrophic hormone test showed no significant change in the blood eosinophil count or urinary creatinine and uric acid. She was discharged with implanted pellets of desoxycorticosterone acetate after four months in the hospital.

*Final admission* (ten weeks later). While at home the patient was ambulatory but vomited almost daily. She had a spell of confusion three weeks and two weeks before admission. These were of one and four hours' duration, respectively. Eight hours before admission this recurred, and she became unresponsive and later comatose.

Physical examination revealed a comatose woman. There were bilateral basal moist rales. Neurologic examination was negative.

involved with tuberculosis. There remains the possibility of making adrenalin in the sympathetic nerve ganglions. It is possible that she had enough ability to secrete epinephrine from the ganglions scattered throughout the body to give a high blood pressure. But I think it very unlikely.

#### CLINICAL DIAGNOSIS

Addison's disease

#### DR AUB'S DIAGNOSES

Addison's disease

Tuberculosis of adrenal glands

Tuberculosis and amyloidosis of kidney

#### ANATOMICAL DIAGNOSES

*Addison's disease*

*Bilateral cortical infarction of kidneys*

*Tuberculosis of adrenal glands, lungs and lymph nodes*

*Pulmonary edema*

#### PATHOLOGICAL DISCUSSION

DR MALLORY: This patient had the anatomic substrate for Addison's disease—complete tuberculous destruction of both adrenal glands. There was tuberculosis elsewhere—it was very extensive in the lungs, though of a low degree of activity. There were also numerous tuberculous lymph nodes scattered throughout the body. The right knee was explored and showed an anatomic fusion of the joint but no evidence of tuberculosis. We unfortunately did not know about the symptoms in the other knee, which was not looked at.

The kidneys were a considerable surprise. They weighed 260 gm. The cortex was 4 or 5 mm in thickness and very slightly scarred, but on microscopical examination it is evident that there was almost complete infarction of the renal cortex. Only a very narrow rim of cortex at the periphery just beneath the capsule and the pyramids was still

visible. This symmetrical cortical infarction, of course, is well known as a complication of pregnancy but does occur in other conditions, and occurs occasionally in members of the male sex. I have never heard of it before in relation to Addison's disease. Whether it can be linked directly to the Addison's disease or should be considered a peculiar complication of the therapeutic measures utilized I cannot answer. It can readily be explained by the mechanism that Trueta\* has recently described of reflex shunting of the renal blood flow into the vasa vitae of the pyramids, with consequent cortical ischemia.

DR AUB: Was there any amyloidosis?

DR MALLORY: No, there was a moderate amount of still recognizable focal lymphocytic infiltration in the kidneys. I think a moderate grade of pyelonephritis existed before this final episode, which was very acute—of only two or three days' duration, I would guess.

DR BENJAMIN CASTLEMAN: Do you think that the kidney lesion was the cause of death?

DR MALLORY: I think that the renal lesion undoubtedly had a great deal to do with death and probably was the immediate cause. There was a moderate grade of pulmonary edema.

DR COPE: Was the renal lesion the probable cause of hypertension?

DR MALLORY: Hypertension is characteristic of the syndrome of symmetrical cortical necrosis.

DR AUB: This case demonstrates an important potential in the Addisonian patient. In the past I have seen a patient menstruate normally in the midst of an Addisonian crisis in spite of a lack of the adrenal hormones. Here we see an example of a Goldblatt hypertension during a crisis, which demonstrates that the mechanism of this hypertension is distinct from the adrenal gland.

\*Trueta, J. et al. *Studies of the Renal Circulation*. 187 pp. Springfield, Ill.: Charles C. Thomas, 1947.

When one is presented with a problem like this, one can always bring in a great many diagnoses just for the sake of naming the diagnosis, but I do not like to do that. I think this woman died of Addison's disease with tuberculosis of both adrenal glands. There is evidence for tuberculosis in what I take to have been a tuberculous knee joint, tuberculous salpingitis and also scrofula in the bone. I would expect that she had tuberculous lymph nodes scattered through the abdomen and that she had a tuberculous peritonitis.

What about the kidney? The urine had a low specific gravity and red cells and a good deal of albumin at the end. She may have had amyloidosis or, what is much more likely, tuberculous involvement of the kidneys, which did not show up in the poor pyelogram that was done. She obviously had something seriously wrong with the kidneys. Let us make two diagnoses: tuberculosis and amyloidosis of the kidneys. Of course, she may have had a malignant tumor involving both adrenal glands, which had destroyed them, with widespread metastases. I do not think we have enough evidence to make such a diagnosis. Recalling the high blood pressure, I think it possible that she was over-treated with intravenous salt on the last entrance to the hospital and that, as a result, she had edema of the lungs with cardiac decompensation. This may be wrong, because with high blood pressure and low blood sugar, the tendency would have been to give glucose and water and not glucose and salt, yet I suggest that she had edema of the lungs. I think she had Addison's disease, which did not respond to desoxycorticosterone acetate because the carbohydrate metabolism was abnormal. It is obvious that with such an abnormality the prognosis is grave, and the response to adrenocortical extract is not always good, particularly if there is an active tuberculosis or other infection.

DR TRACY B MALLORY: Dr Bauer, did you see this patient?

DR BAUER: Yes, indeed, I did. I saw her during the second hospital admission because of her joint disease. One of the members of our group had seen her some months before and thought she had mild rheumatoid arthritis. I must say that when I saw her there was very little in the way of objective findings in the left knee that one could be certain of. The diagnosis rested between tuberculosis and rheumatoid arthritis, however, there was no way of proving either diagnosis. I saw this woman quite a few times and must admit that I felt very strongly that her symptoms were largely psychogenic in nature despite some pigmentation and findings that were in keeping with Addison's disease. Dr Lindeman saw her and agreed to the possibility of a psychogenic illness, however, he did not think it was the sole cause of her chief complaints. What psychotherapy she received from him was the result of my insistence. I think she

received very adequate therapy for the adrenal insufficiency.

DR DANIEL S ELLIS: It is hard now to believe that there was as much difficulty in arriving at a decision in this case as there actually was. But as Dr Bauer has intimated, the diagnoses considered ran from psychoneurosis to cancer. One observer felt very strongly that she should be operated on. What puzzled us on the long second admission was that she did not respond to adequate therapy for adrenal insufficiency. There were doctors of the house staff and some others who felt strongly that it was, without question, a serious consideration and an important one.

Dr Aub asked for certain things that I might supply as far as I can. The basal metabolic rate was +1 and -8 per cent, and the water-excretion test was not done because of the opinion that it was not so accurate as the eosinophilic and uric acid test with adrenocorticotrophic hormones. The results of these, as given in the protocol, were definitely consistent with Addison's disease. There was no change in the uric acid excretion, and the eosinophilic count remained the same, which is true in Addison's disease. Normally, the eosinophilic count falls, and there is increase in uric acid excretion. During the time between the second and third admissions she was at home. For the first month at home the blood pressure was around 105 systolic, 60 diastolic. Because she began to vomit more and eat less and continued to lose weight, in addition to fluids, we decided to give her 5 mg of adrenocortical hormone a day intramuscularly. This was done for another four weeks without any apparent effect. Then she had the onset of these episodes of loss of consciousness, and it was found that at each of the three episodes the blood pressure was higher than it had been on admission: 130 systolic, 70 diastolic, at the first episode, 155 systolic, 90 diastolic, at the second, and 170 systolic, 100 diastolic, at the last. As far as the last admission is concerned, it was believed that she was in a hypoglycemic crisis when she came in. No additional adrenal hormones were given at first, she was given intravenous glucose, and twelve hours later the blood pressure fell to 70 systolic, 40 diastolic. At that time she was given lipoadrenal extract for obvious reasons, which I cannot go into now. It was felt that diuretic therapy should not be given this patient and as far as specific therapy for Addison's crisis was concerned, over a course of thirty-six hours she received 3 cc of lipoadrenal extract and 5 cc of desoxycorticosterone acetate and that is all.

DR AUB: I am fascinated by the elevation of blood pressure with the hypoglycemic reaction. With hypoglycemia one gets increased flow of epinephrine. That might raise the blood pressure, but in Addison's disease, one would not expect it, for the adrenal medulla should not be available if

suggested by the Professional Advisory Committee of the study, with the public-school system, in any event, the profession of nursing the medical profession and the public must be interested and sympathetic in creating a desirable position for the attendant nurse

Certain other observations and recommendations have been made in Dr Brown's report. Of the group of 1125 schools of nursing that participated in the program of the Cadet Nurse Corps, only 13 per cent received a rating by the United States Public Health Service of good or better. This group is made up of the schools that are producing the graduate nurses of today. The current graduate bedside nurse may, indeed, disappear from the scene when nursing of the future is organized on the two levels proposed.

One of these levels will consist of the professional nurses whose training will be limited to the schools that can provide instruction of a grade recognized by educators as professional. These schools will belong in institutions of higher learning and will furnish both cultural education and first-class technical training. They will be on a par with the other university schools and their graduates, as bachelors of science, will serve in technical fields in community health services, in supervisory activities, in executive positions, and in research and teaching.

The nonprofessional nurses with their more limited training, will supply the bedside nursing in the hospitals of the future and, presumably, of the nation's homes. The great need for adequate household service seems to have been largely lost sight of in the preoccupation of the report with the demands of institutions and their hospitalized patients. There are, however, those who still remember that many of the vigils that the nurse must hold in discharging her highest functions are by the sickbeds in the home. Perhaps this need will be met to an increasing degree inside the family itself by those who have profited from the Red Cross Home Nursing courses. God helps those, it is still widely believed, who help themselves.

Nursing, like all the other activities in which humankind engages, is passing through one of its crises. There is, it is said, a shortage of nurses, but

as with the shortage of physicians it is the result of an increased demand for a type of service rather than of any relative decrease in the personnel capable of providing it.

The Commonwealth of Massachusetts is meeting the problem perhaps as intelligently as any state. There is here already the licensed attendant nurse who is filling a need and has achieved a dignity of her own. She is moreover gaining in prestige and in recognition by her more highly trained nursing colleagues.

The profession of nursing needs more help and less criticism, more in the way of respect and less in the way of condescension from others. Perhaps it is not too much to expect that it may some day have its own board of registration with a nurse as secretary and that the Massachusetts Medical Society, as an indication of its own desire to cooperate, may create a special committee to meet with the Massachusetts State Nursing Association.

---

## INFLUENZA AND PNEUMONIA

EACH year after the leaves have fallen the winds and the chill in the air herald in a new "respiratory season." People begin to get colds, many of them have coughs that seem to hang on, and doctors encounter cases of pneumonia and wonder whether there will be any severe outbreak of influenza. Thirty years ago, late in the summer of 1918, a worldwide epidemic struck the Atlantic seaboard and soon swept across the country, attacking about 20,000,000 people in the United States, of whom an estimated 550,000 died of the disease or its complications. Previously, such major outbreaks had recurred at intervals of about twenty or thirty years. Though there has been no cyclic regularity to the occurrence of such pandemics, there is an understandable apprehension that one may strike again. The dread of pandemic influenza is heightened, of course by the lack of precise knowledge concerning the true cause of the previous great pandemics, and for that reason only slight solace can be taken from the vast amount of recently accumulated knowledge concerning the comparatively mild epidemics due to the influenza A and B

## PRO RE NATA

THE world is always in revolution. Sometimes its shifts and changes, and re-alignments are so quiet that they signify only the placid progress of a world at peace, at times, like the present, they consist of such general turbulence that every race, every social and economic group, every industrial and professional alliance seems to be pressing for room in which to function, for prestige, sometimes for existence itself.

Less than a hundred years ago nursing rose from a menial service, often degrading in character, and attained the distinction of a profession. Today this profession finds that it must again adapt itself to violently changing conditions of supply and demand and of social unrest and must find the position that

will secure for it the broadest possible field of future usefulness.

In this contingency the National Nursing Council turned to the Russell Sage Foundation for assistance. A study has been made by Esther Lucile Brown, Ph.D., director for the Foundation of the Department of Studies in the Professions, and her report, *Nursing for the Future*, a review of which is published elsewhere in this issue of the *Journal*, is the tangible result.

Maintenance of health rather than the treatment of disease is the future goal of medicine as horizons expand in medical care, in hospitals and in private practice, in public health and in preventive medicine. Nursing must keep pace with these expansions of health services. Hospitals and all the other agencies of health will need an enormous supply of nursing care, and, as "private duty has become proportionately less important," according to Dr. Brown's thesis, "salaried institutional, public health and industrial nursing has come to be largely considered a social necessity."

Nursing service must be still further differentiated according to function. Not only must the place of the registered graduate nurse be considered, but also the necessity for other grades of nurses. Someone must carry on the simpler functions of nursing at a cost to the consumer that will not put decent care in sickness beyond the reach of the ordinary patient.

The status of the practical nurse must be fixed by legislation, but the attractiveness of her position will depend on the interpersonal relations that will exist in the schools of her training and the situations in which she will work. So far there has been an inevitable tendency on the part of the graduate nurse to disparage the use and the quality of less highly trained personnel that introduces the element of lower-priced competition. This attitude must change if the officers of the nursing corps of the future are to find any devotion and loyalty in the ranks.

The position of the practical or the attendant or the bedside nurse must be made secure, and her training must be carried on partly inside the hospital, where her school may coexist with that of the professional nurse. This may also be linked, as

## DEATHS

**DAHLEN**—Carl A. Dahlen, M.D. of Brookline, died on October 23. He was in his fifty-seventh year.

Dr. Dahlen received his degree from Tufts College Medical School in 1918. He was a member of the dermatologic staff at Massachusetts Memorial Hospitals and was a fellow of the American Medical Association.

His widow, a son, a daughter and two sisters survive.

**HOLT**—Earl K. Holt, M.D., of Medfield, died on November 10. He was in his sixtieth year.

Dr. Holt received his degree from Indiana University School of Medicine in 1914. He was superintendent of the Medfield State Hospital and a member of the American Psychiatric Association and the New England Society of Psychiatry.

His widow and a son survive.

**RAYMOND**—Loring H. Raymond, M.D. of Somerville died on November 6. He was in his seventieth year.

Dr. Raymond received his degree from Harvard Medical School in 1903. He was a fellow of the American College of Surgeons and the American Medical Association.

His widow survives.

†Six year median

#### COMMENT

The diseases with an incidence above the seven-year median were chicken pox, diphtheria, measles and mumps.

The diseases with a prevalence below the seven-year median were bacillary dysentery, meningococcal meningitis, lobar pneumonia, poliomyelitis, pulmonary tuberculosis and whooping cough.

Chicken pox was at the highest level ever reported for October, which may indicate that it will continue at the high level of recent months.

Diphtheria was at the second highest level since 1955. The communities primarily affected continued to be Boston and those immediately to the north.

Measles was at the highest level for October since 1928. It seems likely that the high prevalence of recent months is to continue.

Mumps was at the highest level ever reported for October. A continued high prevalence can be expected during the coming season.

Only three times in the past has scarlet fever been lower in October than prevalence recorded for the month. The high prevalence of recent months after repeated record low levels last year, makes it likely that the disease will be on the increase during the coming season.

Whooping cough was at the lowest prevalence recorded since 1916. It is unlikely, however, that this low figure can be maintained, and the coming season will probably show a considerable increase.

#### GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Arlington, 2; Berkley, 1; Boston, 14; Cambridge, 1; Chelsea, 1; Danvers, 1; Easton, 1; Everett, 1; Hanover, 1; Malden, 3; New Bedford, 1; Somerville, 1; Watertown, 1; total, 29.

Dysentery, amebic, was reported from Stoneham, 1; total, 1.

Dysentery, bacillary, was reported from Stoneham, 1; Newburyport, 1; Worcester, 3; total, 5.

Encephalitis, infectious, was reported from Clinton, 1; total, 1.

Lymphocytic choriomeningitis was reported from Cambridge, 1; Worcester, 1; total, 2.

Malaria was reported from Barnstable, 1; total, 1.

Meningitis meningococcal was reported from Boston, 2; Haverhill, 1; Lynn, 1; Randolph, 1; Worcester, 2; total, 7.

Meningitis Pfeiffer bacillus, was reported from Hatfield, 1; Lawrence, 1; total, 2.

Meningitis pneumococcal, was reported from Barnstable, 1; total, 1.

Meningitis undetermined was reported from Andover, 1; Beverly, 1; Brockton, 1; Dudley, 1; Northampton, 1; Spencer, 1; Weymouth, 1; Worcester, 1; total, 8.

Poliomyelitis was reported from Amherst, 1; Attleboro, 1; Belmont, 1; Boston, 2; Brookline, 1; Cambridge, 1; Danvers, 1; Littleton, 2; Lynnfield, 1; Marblehead, 1; Medford, 1; Middleboro, 1; Palmer, 1; Plymouth, 1; Salem, 2; Shrewsbury, 1; Springfield, 2; Warren, 1; Wellesley, 1; West Springfield, 1; Worcester, 5; total, 31.

Salmonellosis was reported from Beverly, 2; Stoneham, 1; Wakefield, 1; Worcester, 4; total, 8.

Septic sore throat was reported from Boston, 9; Lynn, 1; Stoneham, 1; West Newbury, 1; total, 12.

Tetanus was reported from Cambridge, 1; Pittsfield, 1; total, 2.

Trachoma was reported from Lynn, 1; total, 1.

Trichinosis was reported from Boston, 1; Fall River, 1; total, 2.

Typhoid fever was reported from Brockton, 1; Springfield, 1; total, 2.

Undulant fever was reported from Hallowell, 1; Norwood, 1; total, 2.

## BOOK REVIEWS

*Nursing for the Future*. By Esther Lucile Brown, Ph.D. 198 pp. New York: Russell Sage Foundation, 1948. \$2.00.

The avowed objective of Dr. Brown's "Nursing for the Future" is refreshing. She states: "First, and most important, was the decision to view nursing service and nursing education in terms of what is best for society—not what is best for the profession of nursing as a possibly vested interest." Quite rightly she says of the nurses that "Many have kept their attention so focused upon professional rights and prerogatives that society has sometimes come to question their interest in serving the needs of our national life."

How closely the author adheres to her objective might be questioned, but her report based on painstaking investigation contains many facts and observations that should be helpful. "So long as attention is centered on the graduate nurse, no other avenue is open except that of the present frantic and probably futile effort to recruit more prospective R.N.'s. Even appreciably better educational preparation is likely to be denied them, so insistent will the demand for nursing service continue to be. Once emphasis is shifted to nursing, however, several roads seem to point to potentially larger supplies of service and to possibly increased efficiency, both on the nonprofessional and the professional levels." It is cheering to learn this.

viruses that have been recurring every two or three years

Some comfort may, nevertheless, be derived from a recent review by the statisticians of the Metropolitan Life Insurance Company\* of the figures on mortality from influenza and pneumonia during the past few years. A most significant downward trend in the figures began in the early 1930's, when specific serum treatment for many types of pneumonia was introduced. Among the Company's industrial policyholders the death rate dropped from 80 per 100,000 in 1930-31 to about 70 per 100,000 in 1936-37, the period during which this type of therapy came increasingly into use. In 1938, when both serum and the sulfonamides were used, the death rate from pneumonia and influenza dropped sharply to 47 per 100,000—a decrease of almost 35 per cent from the year before. Improvements in sulfonamide treatment and the introduction of penicillin brought still further success so that by 1947 the death rate reached an all-time low of 17.4 per 100,000, and it is expected that this will fall still further during the current year. The efficacy of newer methods of treatment is clearly evident from the fact that improvement in mortality has been relatively three times as great in the past decade as in the previous one. Between 1935-37 and 1947 the decrease was more than 60 per cent in every age group among white persons of both sexes, and in most age groups the reduction in the death rate was greater than 75 per cent.

Some forms of pneumonia are still not amenable to treatment. Some of the virus pneumonias are in this category, and there is always a possibility that some virulent form of these pneumonias will occur. Moreover, there is no assurance that a devastating epidemic of influenza similar to that of 1918 will not strike again. So far this year, however, there are no signs pointing to the likelihood of a severe influenza epidemic in the United States or elsewhere. This is unlike the situation in 1918 when months before there were serious outbreaks in various military installations in this country and also in various parts of Europe. Even if such an epidemic should occur, the medical and public-

health professions are much better prepared to cope with the situation now than they were thirty years ago. It is well recognized that the uncomplicated cases of influenza cause relatively few deaths even during pandemics. Most of the deaths occur among cases complicated with severe forms of pneumonia. With the help of the sulfonamides, penicillin and other antibiotics that are now available, physicians should be able to control the complications and thus rob the next pandemic of most of its terrors.

### EMINENT CARDIOLOGIST

DR. PAUL DUDLEY WHITE, of Boston, has been appointed chief adviser for the National Heart Institute and executive director of the National Advisory Heart Council, established by Congress last June as an activity of the United States Public Health Service. Dr. White, who has been physician in charge of the Cardiac Clinic and Laboratory of the Massachusetts General Hospital, has resigned from that position to assume his new duties, which will require a division of time between Boston and the headquarters of the National Heart Institute at the National Institutes of Health, Bethesda, Maryland.

A graduate of Harvard College in the class of 1907 and of the Harvard Medical School in 1911, Dr. White in April, 1948, received the Order of the White Lion from the Czechoslovakian Government, on the occasion of the six hundredth anniversary of the founding of Charles University, in Prague. This award was made as the result of his participation in the medical mission of the Unitarian Service Committee to Czechoslovakia in 1946.

### MASSACHUSETTS MEDICAL SOCIETY HAMPDEN DISTRICT

The Hampden District Medical Society is to be congratulated on the excellent manner in which it has responded to the request of the Council, made in May, that the districts form their own plans for full-time coverage of calls for physicians.

Lists have been issued classifying the members of the district society according to types of practice, and from these a house-call classification sheet has been constructed containing the names of those physicians in the various communities of the district who are willing to respond to emergency calls, and the times at which they are available.

BOOK REVIEWS

*Nursing for the Future* By Esther Lucile Brown Ph.D  
198 pp New York Russell Sage Foundation 1948 \$2.00  
The avowed objective of Dr Brown's "Nursing for the Future" is refreshing She states, "First, and most important, was the decision to view nursing service and nursing education in terms of what is best for society — not what is best for the profession of nursing as a possibly 'vested interest'" Quite rightly she says of the nurses that "Many have kept their attention so focused upon professional rights and prerogatives that society has sometimes come to question their interest in serving the needs of our national life"  
How closely the author adheres to her objective might be questioned, but her report based on painstaking investigation, contains many facts and observations that should be helpful "So long as attention is centered on the graduate nurse, no other avenue is open except that of the present frantic and probably futile effort to recruit more prospective R.N.'s Even appreciably better educational preparation is likely to be denied them so insistent will the demand for nursing service continue to be Once emphasis is shifted to nursing however several roads seem to point to potentially larger supplies of service and to possibly increased efficiency both on the nonprofessional and the professional levels"  
It is cheering to learn this

Observing that everyone desires the best in nursing service but that competent graduate nurses must be used for supervision, administration and teaching, Dr Brown wisely concludes, "We are still far from discovering a financial method whereby the finest in nursing could be furnished to everyone in need. At least it is assumed that neither the patient nor the institution should pay for graduate nursing, if any part of that nursing could be done as efficiently by persons with shorter preparation." Only too true is her statement that the profession has difficulty in visualizing concomitant assistant and professional nursing services, but without them, she says, "we shall almost inevitably have to continue to depend on the graduate bedside nurse as we do today, regardless of the fact that her training has been too long and expensive for performing the simpler functions."

Dr Brown then proceeds to outline three grades of nursing service: professional, nonprofessional and an intermediate group. "In the case of the graduate general nurse, however, emphasis needs to be placed only on preparation for bedside care and some understanding of what constitutes a complete health service." She calls attention to the fact that the Committee of Interests in Accreditation "visualized three classes of members: schools offering the basic curriculum, schools offering advanced curricula, and schools preparing practical nurses." If we add to this the proviso that those demonstrating the ability may progress from grade to grade, we have in effect the recommendation recently adopted by the American Medical Association. When such groups of nurses and physicians are in agreement that three grades of nurses should be trained, and the former comes to the realization that with this plan "nurses will be given a better opportunity to devote themselves to those aspects of clinical practice that require true professional skill," progress should be swift.

Many hospitals, says Dr Brown, are discussing the opening of such schools for practical nurses in addition to their "regular" schools, but "At present provisions for the preparation of practical nurses are negligible when compared with what are needed." "What is advocated is conviction, not lip-service alone, on the part of the nursing profession, hospital administrators, and the laity concerned with social change, that new patterns of nursing service must be evolved both in behalf of adequacy of supply and of quality." And further, "No system of training for practical nurses is likely to succeed unless the public educators, hospitals, nursing associations and state boards of control are prepared to manifest an active interest in practical nursing far beyond any interest yet shown." "Not only the availability of nursing care for large portions of the population, but also the future status of professional nursing itself will be determined by the degree to which rapid and effective action can be achieved in this long neglected field."

In the last two thirds of the book, Dr Brown seems to forget the original objective of what is best for society and to fall under the influence of her advisory committees, composed almost entirely of the leaders of advanced nursing education and from the academic sphere. Since the poor patient is inarticulate, the counsel of a committee of hospital administrators charged with his bedside care, and of doctors responsible for the therapy administered by the nurse might have been helpful. In spite of the fact that there is a dearth of top-grade nurses for administration, teaching, and the aspects of clinical practice requiring true professional skill, Dr Brown points out that even where university affiliation exists, "Relatively few of these students have exhibited an interest in obtaining a degree." Under these circumstances, the emphasis on the need for greatly expanding the opportunities for truly higher education may be questioned, and those primarily interested in the care of the patient may resent the repeated reference to the hospital as the "laboratory" for such institutions of learning. It perhaps recalls too sharply the point of view of the student who wrote, "The patient is the medium through which the nurse expresses her personality."

Aside from this overemphasis on higher education, Dr Brown's book contains much valuable information and common sense. It will be a pity if hospital administration does not integrate the points presented into a plan of action to extricate itself from the present dilemma of nursing service.

*The Pathology of Nutritional Disease*. By Richard H. Follis, Jr., M.D. 8°, cloth, 291 pp., with 71 illustrations. Springfield, Illinois: Charles C. Thomas, 1947. \$6.75.

To those who have not had the opportunity of following the literature on nutrition as it has developed, the problem of orientation in such a complicated, widely applied and somewhat confused field is likely to require so much time as to be prohibitive. Consequently, the appearance of a book that aims at a stocktaking and a clarification of confused issues is warmly welcomed by students and clinicians, if not by those in the research field.

Dr Follis has undertaken the rather ambitious task of discussing the pathophysiology and histopathology resulting from a deficiency of forty-two nutrients essential to mammalian metabolism. He has wisely eliminated many of the early investigations in which the findings were complicated by a multiplicity of deficiencies; he has attempted to restrict himself to those in which, so far as present knowledge is concerned, a single deficiency acts as a limiting factor. The result is a clear demonstration of the wide gaps in knowledge of the specific roles of many of the so-called dietary essentials. Regarding human metabolism these gaps are exceedingly large, and somewhat startling, when compared with the abandon with which the nutrients are used in clinical medicine.

Not only does the author discuss the specific effects of single deficiencies, but also, whenever possible, he indicates the interrelation of various factors. Thus, the interrelations of choline, methionine and cystine, of tryptophan and niacin, of ascorbic acid and phenylalanine and tyrosine and so forth are briefly but concisely considered.

Since the factors discussed are likely to be essential for a variety of tissue cells, it is not surprising that a deficiency of any one may be manifested by morphologic and physiologic lesions in a number of different tissues. Conversely, distortions of structure and function may develop in a given tissue as a result of a deficiency of several factors occurring independently. The author has attempted to emphasize this by approaching his subject initially from the point of view of the individual factors and finally from the point of view of specific tissues.

In this era of unbridled enthusiasm over various concoctions of essential nutrients, it is a healthy sign that a book such as this has been written. If it succeeds in but one thing — a serious re-evaluation of the use of vitamins in clinical medicine — it will have served a useful purpose.

*Brief Psychotherapy: A handbook for physicians on the clinical aspects of neuroses*. By Bertrand S. Frohman, M.D. With the collaboration of Evelyn P. Frohman, and with a foreword by Walter C. Alvarez, M.D. 12°, cloth, 265 pp. Philadelphia: Lea and Febiger, 1948. \$4.00.

This handbook, written particularly for the general practitioner, has many features that will make it attractive to the beginner in psychiatry. Its simple, direct presentation and good glossary make it useful also for the educated patient.

Although it stresses practical clinical approach, theory has been cleverly introduced into the discussions, and advanced in an appealing manner. Case reports, brief and to the point, are interspersed throughout the text. Failures and difficulties are admitted — a rare finding in psychotherapeutic literature.

The psychoneuroses are carefully differentiated, and pitfalls in diagnosis are shown. Etiologic factors are reviewed in an excellent section, being separated according to age groups. There are special chapters on neuroses encountered in the specialties.

The main methods of treatment are given with their indications, and brief psychotherapy is described in more detail. There is a good bibliography.

The orthodox psychoanalysts will disagree with much that is presented in the section on therapy, and there are a few other points in the text that one might criticize. Despite these minor considerations, the book is a most welcome addition to the small group, now available, that present psychotherapy in a concise and practical form for the general practitioner.

*Diabetes Mellitus in General Practice* By Arthur R. Colwell, M.D. 8°, cloth, 350 pp., with 24 illustrations. Chicago: The Year Book Publishers, Incorporated, 1947. \$5.25.

Dr Colwell is such an outstanding investigator and physician that his book on diabetes mellitus is sure of a welcome. Although not conventional, it is certainly provocative that he omits the word pancreas in the first paragraph, captioned "Definition," of the first chapter. All doubt, however, of the writer's belief in the unity of diabetes is dispelled in the pages that follow. Interestingly, he brings out the connection between the anterior pituitary body, the suprarenal glands and the thyroid gland and shows that in the presence of hyperfunction of these ductless glands hyperglycemia and glycosuria are apt to occur. For practical purposes he concedes that diabetes mellitus is a relative insulin deficiency except when specific pituitary, adrenal, thyroid or sympathetic overactivity can be demonstrated and removed.

The reviewer is sure that Dr Colwell did not fully consider the implications of another sentence in that first paragraph which reads as follows: "The anomaly of glucose metabolism with ketosis is subject to control by diet and insulin but the course of the disorder and its arteriosclerotic complications are not influenced to any major degree." But the reader can be assured that the author does enthusiastically believe in the active treatment of the disease and that he points out these results in the retardation of its progress. He emphasizes the desirability of prophylaxis and treatment in the prediabetic stage. This is brought out in his discussion of heredity, in which he cites the anticipation of diabetes in succeeding generations, quoting the work of Woodruff and Spetz and notes the possibility that diabetes will eventually work itself out. He enlarges on this point by describing the rate of progress, rapid in youth and slow in advancing years of diabetes, and then suggests that if these slants are extended backward they converge at the approximate time of birth, indicating that the diabetes of a predetermined type is inherited. He goes so far as to suggest that its course is approximately half run by the time it is recognized clinically. Whether diabetes will work itself out in the fourth or fifth generation will soon be known. There are so many diabetic children now who have grown up and married that it will not be long before it can be determined whether the incidence of diabetes in their offspring, the presumable fourth and fifth generations is actually greater than that in the second and third. Before drawing conclusions, however, one must remember that only one in 25,000 persons under fifteen years of age was found to be diabetic by the National Health Survey.

All interested in diabetes will regard as important the following statements:

Diabetes at the stage, before glycosuria is persistent and harm has occurred, is easily treated and its progress prevented or delayed. It is important to recognize it early and treat it meticulously. Temporary improvement could become permanent, as indicated by animal experimentation, if mild diabetes were taken as seriously as severe diabetes and if the idea of protection from permanent islet damage were entertained. Much diabetes which could be kept innocuous by consistently good control is permitted to become severe because of complacency in regarding the lack of associated symptoms and ease of desugarizing.

The blame for this complacency the author puts largely on the medical profession. By control of diabetes he means control of the hyperglycemia. He is convinced that one should first get the patient sugar free and then increase the carbohydrate slowly as advocated generally by the best European clinicians of a former generation.

The description of the various insulins is excellent, and physicians are indebted to Dr Colwell for details of their manipulations, especially for the description of his own method of mixing two parts of quick insulin with one part of protamine zinc insulin in one syringe. The reviewer agrees with his preference for a syringe of 1-cc capacity divided in tenths. The details of the technique of administering insulin are excellent.

The section on acidosis (forty-three pages) is seriously written but prolix. One wishes the author had seen fit to insert in two or three pages a summary of H. F. Root's version of treatment of diabetic coma, which has been approvingly recognized by R. H. Nicks in a study entitled "Diabetic Coma" (*Bull. M. J.* 2:200-203, 1948). There is always a reason for a writer's adherence to certain methods. This is disclosed by hints here and there that he has so often waited

long for laboratory reports that he has tried to build up a safe method of treatment without them. The reviewer is positive that if Dr Colwell had been afforded reports of blood sugar and carbon dioxide tests within thirty or forty minutes after request, his treatment of diabetic coma would have been entirely different. It is regrettable that his results of treatment are not presented. Potassium is not mentioned although the fish-mouth syndrome might well have occurred in some of his cases since deficiency of potassium is almost exclusively confined to patients treated with injections of glucose or enormous quantities of liquids.

Issue at once must be taken with the following statement upon arteriosclerosis:

It is generally true that the most severe diabetes is not uniformly associated with vascular disease. There is no constancy in the relationship between the severity of the disorder of sugar metabolism and vascular disease, indeed if anything, the reverse seems to be true.

All grades of arteriosclerosis occur in the young as well as in the old, varying with the duration and control of the diabetes. It is not strange that the smaller blood vessels are as notably affected in the young as in the old although for the early manifestations of the arteriosclerotic process in youth one looks most commonly for calcification demonstrable by x-ray examination in the vessels about the ankles, the lower legs and the pelvic arteries. Indeed, the calcification of the pelvic arteries in young female patients with diabetes is one of the best prognostic indications of whether the patient will have a living child. The relative clinical absence of gangrene, cerebral and myocardial lesions of vascular origin in the young is largely due to the malignancy of the vascular disease in the kidneys prematurely shortening life, as is shown at autopsy.

It is regrettable that transmetatarsal amputations, described by McKittrick several years ago and carried out on a large scale, are not even mentioned, because this operation often results in the prevention of an amputation of the thigh. Similarly, it is surprising that after amputation it is advised that the stump should be left open. Nearly a generation ago this practice, at least in this vicinity, was ended by Dr Daniel Fiske Jones. Under no circumstances can one subscribe to the efficacy of penicillin ointment, which in the war proved to be less effective even than Dakin's solution. One would also deny the following statement: "The procedure of greatest value is the use of continuous warm moist compresses of generous thickness which is kept warm with an automatic heat cradle and not permitted to dry out." Warmth in the treatment of active infection we thought belonged to a former era and was even as outmoded as soaking a foot. As a matter of fact, no local surgeons have been heard to recommend soaking of an extremity in any kind of liquid during the last twenty years. In the discussion of carbuncles Dr Colwell suggests that the best available method of treatment is radical incision. Years ago that was true, but since the advent of the sulfonamides and penicillin the carbuncles disappear like dew before the sun, and operation upon a carbuncle is a rarity.

Again, the reviewer cannot subscribe to the idea that "the treatment of diabetic polyneuritis is just about as ineffective as anything in the entire field of medicine." It is granted that treatment is not spectacular in days or weeks, but it is spectacular in months and so remarkable that patients who have been cured are always available, even though they live at a distance, to come to the hospital to cheer a sufferer in the active stage. Moreover, one should combat the idea that the symptoms of neuritis flare up with the beginning of treatment. Careful questioning practically always elicits the presence of these symptoms long before, although they may have been in the background, because of the more intense symptoms associated with the nonutilization of glucose, the "polys," pruritus and loss of weight and strength.

Fat atrophy is very common. The reviewer cannot agree that it "usually is permanent and harmless," because in his experience, especially in children, fat atrophy is temporary.

This book is strongly recommended despite the few criticisms mentioned. It is truly provocative and stimulating. The reviewer knows that he has profited greatly by the hours spent in its perusal and that his own patients will benefit thereby, particularly because of the author's insistence upon very early and aggressive treatment of the disease and the hope thus awakened for its control and the prevention of disturbing complications.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Medical Research in War.* Report of the Medical Research Council for the years 1939-45. Committee of Privy Council for Medical Research. Presented by the Lord President of the Council to Parliament by Command of His Majesty, December, 1947. 8°, paper, 455 pp. London: His Majesty's Stationery Office, 1948. 7s. 6d.

This important document summarizes the research work done by the various divisions of the Medical Research Council. Of particular interest are the reports on wounds and injuries, war diseases, penicillin and nutrition. A list of selected references is appended to each subject. The text is well printed on good paper. The monograph should be in all medical libraries.

*Diseases of the Chest Described for students and practitioners.* By Robert Coope, M.D., B.Sc., F.R.C.P., consulting physician, King Edward VII Sanatorium, Midhurst, physician, Liverpool and North-Western Chest Surgical (E.M.S.) Unit, visiting physician, Maghull Epileptic Homes, lecturer in clinical medicine, lecturer in applied physiology and lecturer in clinical chemistry, University of Liverpool, and examiner in medicine in the university of Liverpool, London and Aberdeen. With a foreword by Lord Horder. Second edition. 8°, cloth, 541 pp., with 134 illustrations and 34 color plates. Baltimore: The Williams and Wilkins Company, 1948. \$7.50.

This second edition of a book first published in 1944 has been revised to the extent of correcting certain errors in the description of the anatomy of the bronchial tree. The book was printed in Great Britain and bound in the United States. The type and paper are good, and the color plates are excellent. The volume should prove useful to those interested in the subject.

*Human Neuroanatomy.* By Oliver S. Strong and Adolph Elwyn, associate professor of neuroanatomy, College of Physicians and Surgeons, Columbia University. Second edition. 4°, cloth, 442 pp., 336 illustrations. Baltimore: The Williams and Wilkins Company, 1948. \$6.00.

The text of this new edition of a work, first published in 1943, and reprinted three times, has been revised, but not materially changed. A chapter has been added on segmental peripheral innervations, including a clinicoanatomic survey of the cervical, brachial and lumbosacral plexuses and of the main peripheral nerves. The chapter on the blood supply of the brain has been expanded to give a more complete and fully illustrated account of the arterial supply and venous drainage of the brain. The text is well printed, with a good type in two columns. A selected bibliography is appended. A good index concludes the volume. The book is recommended for all medical libraries and to all surgeons interested in the subject.

*The Hospital Care of Neurosurgical Patients.* By Wallace B. Hamby, M.D., professor of neurology and neurologic surgery, University of Buffalo School of Medicine. Second edition. 8°, cloth, 156 pp., with 30 illustrations. Springfield, Illinois: Charles C. Thomas, 1948. \$3.00.

The second edition of this manual written for nurses and for young physicians has been revised and simplified at the suggestion of its readers. The volume is not intended as a treatise on therapy, which varies greatly in different clinics. A chapter on the relations of house officers has been added to the text.

*Estudios sobre la Coca y la Cocaína en el Perú.* By Carlos Gutierrez-Noriega, M.D., and Vicente Zapata Ortiz, M.D. 8°, paper, 144 pp., with 32 illustrations, 8 tables and 2 plates. Lima: Ministerio de Educación Pública, 1947.

The preliminary chapters of this monograph deal with the history and habitation of the cocoa plant in Peru. The following chapters, based on experimental work, treat of the

physiology, the effects on the nervous system, mental activity and metabolism, and the action on muscular work, resistance to fatigue and toxicity of coca and cocaine.

*The Baby's First Two Years.* By Richard M. Smith, M.D., Sc.D. 12°, cloth, 180 pp., with 15 illustrations. Boston: Houghton Mifflin Company, 1948. \$2.75.

This new edition of a popular manual has been rewritten completely in many sections to conform with recent knowledge concerning the care of infants. The necessity for a fifth edition speaks well for the soundness of the manual, which should prove useful to mothers and others having the care of young children.

*Coronary Heart Disease.* By A. Carlton Ernestine, M.D., chief of the section on cardiovascular disease, Cleveland Clinic, Cleveland, Ohio. 8°, cloth, 95 pp. Springfield, Illinois: Charles C. Thomas, 1948. \$2.50.

This short monograph is simply written, and the material is well arranged. It discusses coronary-artery disease in its various aspects, including angina pectoris, acute myocardial infarction, acute coronary failure, paroxysmal cardiac dyspnea, heart block, disturbances of cardiac rhythm and congestive heart failure. A short chapter on the risk of anesthesia and surgical operations in patients with coronary-artery diseases concludes the text. A selected bibliography and a good index conclude the volume. The text is well printed on good paper and should prove valuable to the practicing physician.

*Physiologic Therapy in Respiratory Diseases.* By Alvan L. Barach, M.D., associate professor of clinical medicine, Columbia University College of Physicians and Surgeons, and assistant attending physician, Presbyterian Hospital, New York City. Second edition. 8°, cloth, 408 pp., with 74 illustrations. Philadelphia: J. B. Lippincott Company, 1948. \$9.00.

The first edition of this book was published in 1944 under the title, *Principles and Practices of Inhalation Therapy*. This new edition includes much new material on other measures than the therapeutic use of gases for counteracting the clinical disorders of breathing. The author defines the term physiologic therapy as treatment designed to restore adequate function to organs impaired by disease. Special emphasis is placed on pathologic physiology. The type and printing are excellent, but the few illustrations do not justify the use of a heavy coated paper. The volume is recommended for all medical libraries and to all physicians interested in the subject.

## NOTICES

### ANNOUNCEMENT

Dr. Field C. Leonard announces the opening of his office at 412 Beacon Street, Boston, for the practice of general surgery in association with Dr. Hollis L. Albright.

### BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

A meeting of the Boston Society of Psychiatry and Neurology will be held at the Boston Medical Library, 8 Fenway, on Wednesday, December 15, at 8:15 p.m.

#### PROGRAM

Topectomy in the Treatment of Psychoses. Dr. J. Lawrence Pool (thirty minutes).

Relief of Intractable Pain by Unilateral Frontal Leukotomy. Dr. John E. Scarff (thirty minutes).

### MASSACHUSETTS TRUDEAU SOCIETY

A meeting of the Massachusetts Trudeau Society will be held in the amphitheater of the Peter Bent Brigham Hospital on Wednesday, December 15, at 8:15 p.m. Dr. René J. Dubos, of the Rockefeller Institute for Medical Research, will speak on the subject "Bacteriologic Aspects of Tuberculosis."

Physicians and medical students are invited to attend.

(Notices concluded on page xxi)

## NOTICES (Concluded from page 944)

NEW ENGLAND SOCIETY OF  
PHYSICAL MEDICINE

A regular meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston on December 15, 1948

## PROGRAM

- 6:00 p.m. Informal Dinner in the Empire Room  
7:30 p.m. Meeting of the Council  
8:00 p.m. Scientific Session Dr. Dwight E. Harken will present an address entitled "Surgery of the Heart" followed by a demonstration of specific remedial breathing exercises illustrated by lantern slides and a sound film

Physicians, medical students and physical therapists are cordially invited

## SOUTH END MEDICAL CLUB

A regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, December 21, at 12 noon. Dr. Earle M. Chapman will speak on the subject "Use of Atomic Energy in Medicine."

## SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING  
THURSDAY, DECEMBER 16

## FRIDAY DECEMBER 17

- \*9:00-10:00 a.m. Albumin in the Treatment of Hypoproteinemia  
Dr. Sam T. Gibson, Joseph H. Pratt Diagnostic Hospital  
\*9:00 a.m.-12:00 p.m. Combined Medical and Surgical Staff Rounds  
Peter Bent Brigham Hospital  
\*12:00 p.m. X-Ray Conference, Margaret Jewett Hall, Mt. Auburn Hospital, Cambridge

## MONDAY DECEMBER 20

- \*12:15-1:15 p.m. Clinicopathological Conference, Main Amphitheater, Peter Bent Brigham Hospital

## TUESDAY DECEMBER 21

- \*9:00-10:00 a.m. Journal review, Joseph H. Pratt Diagnostic Hospital.  
12:00 p.m. South End Medical Club, Boston Tuberculosis Association, 554 Columbus Avenue, Boston  
\*12:15-1:15 p.m. Clinicoradiogenetological Conference, Peter Bent Brigham Hospital  
\*1:30-2:30 p.m. Pediatric Rounds, Burnham Memorial Hospital for Children, Massachusetts General Hospital

## WEDNESDAY DECEMBER 22

- \*11:00 a.m.-12:00 p.m. Medical Rounds, Amphitheater, Children's Hospital  
\*12:00 p.m.-1:00 p.m. Clinicopathological Conference (Children's Hospital), Amphitheater, Peter Bent Brigham Hospital  
\*2:00-3:00 p.m. Combined Clinic by the Medical, Surgical and Orthopedic Services, Amphitheater, Children's Hospital

## DELAYS AND ERRORS IN THE DIAGNOSIS OF BRAIN TUMOR\*

FREDRICK C. REDLICH, M.D.,† REMBRANDT H. DUNSMORE, M.D.,‡ AND EUGENE B. BRODY, M.D.§

NEW HAVEN, CONNECTICUT

**M**OST general practitioners, internists and neuropsychiatrists with a sufficiently large and varied practice sooner or later have the distressing experience of mistaking a brain tumor for a psychoneurosis or of unnecessarily delaying the correct diagnosis. As in other disorders involving behavior, the opinions of family and friends as well as of other lay people in the community, often contribute to confuse the opinions of the physician, particularly of the general practitioner. Such considerations stimulated the present investigation of diagnostic errors made in 100 proved cases of brain tumor.

It is impossible to extract a bibliography on diagnostic errors from the vast literature on brain tumors because such a diagnostic consideration is inextricably involved with other viewpoints in books and papers dealing with the general subject of brain tumors. However, it might be stated that the literature on diagnostic errors may be grouped under three headings. The first comprises general statements by neurologists, neurosurgeons and psychiatrists based on prolonged experience in which the authors reflect on their knowledge and offer their advice and warnings. Some of these reflections are contained in the great classics on the subject by Cushing, Bailey and so forth, and others in papers of the editorial type. A second group consists of case reports; there is a wide discrepancy between the classic monographs and the repetitive and often single and not always spectacular case reports. Characteristic of this group is emphasis on differential diagnosis between various tumors and other conditions or fine differentiations between the tumors themselves. The third group consists of reports on techniques (cerebrospinal-fluid examinations, electroencephalography, radiologic diagnosis and so forth) that help to establish or facilitate the diagnosis of brain tumors. A few papers dealing

explicitly with the diagnostic errors in brain tumors are listed.

Horrax<sup>1</sup> differentiated symptomatologically typical tumors easily diagnosed on the basis of adequate history, physical examination and laboratory study, and atypical ones that should be studied with the particular lesion in mind. He believed that a tumor or something simulating a tumor can almost always be diagnosed provided the patient consents to thorough diagnostic study. McIntyre and McIntyre<sup>2</sup> stated that most errors in the diagnosis of brain tumor were due to lack of "brain tumor consciousness" in the mind of the examiner, failure to realize the importance of an adequate history and repeated neurologic examinations, and failure to realize that headache, vomiting and choked disk are *not* early signs of brain tumor.

Purves-Stewart,<sup>3</sup> who reviewed 115 cases of verified brain tumors, concluded that carelessness or insufficient observation, as well as a tendency to cling to the first conception of the case, was the most important factor in what he called available errors. The main problems in what he termed unavailable errors were too short a period of observation and scanty clinical symptoms. A large majority of the diagnostic errors in the series of Hastings<sup>4</sup> were made in the differential diagnosis of cerebral vascular disease and tumor. Bing<sup>5</sup> discussed intracranial tumors with minimal focal signs presenting difficulties in diagnosis. Many authors have stressed the importance of tumor consideration in patients exhibiting convulsive seizures after the age of thirty. The great value of such technical diagnostic aids as electroencephalographic and air studies is generally recognized, and yet, as Poppen and Peacher<sup>6</sup> point out, these are not invariably reliable and cannot replace diagnostic weapons available to all: an adequate history and neurologic examination.

The present study approaches the problem from the viewpoint of public health. It has seemed that the differential diagnosis that concerns the neurologist so greatly actually contributes little to knowledge of why the diagnosis of brain tumors is unduly delayed or missed. The problem is not one of mak-

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri Maltose.

## DELAYS AND ERRORS IN THE DIAGNOSIS OF BRAIN TUMOR\*

FREDRICK C REDLICH, M.D.,† REMBRANDT H DUNSMORE, M.D.,‡ AND EUGENE B BRODY, M.D.§

NEW HAVEN, CONNECTICUT

**M**OST general practitioners, internists and neuropsychiatrists with a sufficiently large and varied practice sooner or later have the distressing experience of mistaking a brain tumor for a psychoneurosis or of unnecessarily delaying the correct diagnosis. As in other disorders involving behavior, the opinions of family and friends as well as of other lay people in the community, often contribute to confuse the opinions of the physician, particularly of the general practitioner. Such considerations stimulated the present investigation of diagnostic errors made in 100 proved cases of brain tumor.

It is impossible to extract a bibliography on diagnostic errors from the vast literature on brain tumors because such a diagnostic consideration is inextricably involved with other viewpoints in books and papers dealing with the general subject of brain tumors. However, it might be stated that the literature on diagnostic errors may be grouped under three headings. The first comprises general statements by neurologists, neurosurgeons and psychiatrists based on prolonged experience in which the authors reflect on their knowledge and offer their advice and warnings. Some of these reflections are contained in the great classics on the subject by Cushing, Bailey and so forth, and others in papers of the editorial type. A second group consists of case reports; there is a wide discrepancy between the classic monographs and the repetitive and often single and not always spectacular case reports. Characteristic of this group is emphasis on differential diagnosis between various tumors and other conditions or fine differentiations between the tumors themselves. The third group consists of reports on technics (cerebrospinal-fluid examinations, electroencephalography, radiologic diagnosis and so forth) that help to establish or facilitate the diagnosis of brain tumors. A few papers dealing

explicitly with the diagnostic errors in brain tumors are listed.

Horrax<sup>1</sup> differentiated symptomatologically typical tumors easily diagnosed on the basis of adequate history, physical examination and laboratory study, and atypical ones that should be studied with the particular lesion in mind. He believed that a tumor or something simulating a tumor can almost always be diagnosed provided the patient consents to thorough diagnostic study. McIntyre and McIntyre<sup>2</sup> stated that most errors in the diagnosis of brain tumor were due to lack of "brain tumor consciousness" in the mind of the examiner, failure to realize the importance of an adequate history and repeated neurologic examinations, and failure to realize that headache, vomiting and choked disk are *not* early signs of brain tumor.

Purves-Stewart,<sup>3</sup> who reviewed 115 cases of verified brain tumors, concluded that carelessness or insufficient observation, as well as a tendency to cling to the first conception of the case, was the most important factor in what he called available errors. The main problems in what he termed unavailable errors were too short a period of observation and scanty clinical symptoms. A large majority of the diagnostic errors in the series of Hastings<sup>4</sup> were made in the differential diagnosis of cerebral vascular disease and tumor. Bing<sup>5</sup> discussed intracranial tumors with minimal focal signs presenting difficulties in diagnosis. Many authors have stressed the importance of tumor consideration in patients exhibiting convulsive seizures after the age of thirty. The great value of such technical diagnostic aids as electroencephalographic and air studies is generally recognized, and yet, as Poppen and Peacher<sup>6</sup> point out, these are not invariably reliable and cannot replace diagnostic weapons available to all: an adequate history and neurologic examination.

The present study approaches the problem from the viewpoint of public health. It has seemed that the differential diagnosis that concerns the neurologist so greatly actually contributes little to knowledge of why the diagnosis of brain tumors is unduly delayed or missed. The problem is not one of mak-

ing a differential pathological type of diagnosis but of establishing the presence of an intracranial tumor at a stage sufficiently early so that treatment may be effective. The following specific questions must be answered: Does the examination of histories of proved cases of brain tumor suggest unnecessary delays in correct diagnosis? If such delays and errors are found, why do they occur? Who errs and what are the reasons for the errors? What remedies may be suggested?

METHOD

A random sample of 100 brain tumors verified by operation or autopsy or both was chosen and classified according to type and localization. The following aspects of the cases were tabulated: first complaints, first neurologic signs detected, correct

TABLE 1 First Complaints

COMPLAINT	No. of Cases
Headaches	86
Disturbance of eyesight (amblyopia, amaurosis, blurred vision, scotoma and so forth)	36
Gastrointestinal symptoms	
Vomiting	32
Nausea without vomiting	27
Seizures	30
Locomotor unsteadiness (falling, lack of co-ordination and so forth)	29
Double vision, ptosis and so forth	21
Weakness of limbs	21
Personality changes (neurotic complaints)	21
Speech difficulties	19
Dizziness	18
Memory and intelligence deficit	18
Fainting	17
Character changes	15
General weakness and fatigue	14
Drowsiness	12
Loss of bearing	11
Incontinence	9
Weakness of facial muscles	9
Psychoses	8
Amenorrhea	5
Weakness of half of one side	5
Stiffness of neck	4
Weight loss	3
Tremor of hands	2
Tilting of head	1
Loss of sense of smell	1

and false diagnosis by family physicians, correct and false diagnosis after hospitalization before diagnostic study by specialists, correct and false diagnosis by specialists (neurologists, psychiatrists and neurosurgeons), diagnostic contributions of cerebrospinal-fluid studies, air studies and radiologic and electroencephalographic examinations, and time lost between the first appearance of signs and symptoms (when the diagnosis presumably could have been made) and the time of the correct diagnosis. More than one first complaint was often mentioned, but for purposes of tabulation these were broken down into single symptoms (Table 1). Thus, a certain amount of distortion and condensation was unavoidable.

OBSERVATIONS

Pathological Observations

The cases were chosen at random from the files of the Department of Pathology, the Department of Psychiatry and the Department of Surgery. Eighty per cent of the material came from pa-

TABLE 2 Locations of the Tumors

LOCATION	No. of Cases
Temporoparieto-occipital	37
Frontal	24
Posterior fossa	23
Pituitary and hypothalamus	9
Basal ganglions	7
	100

tients who had died, 74 per cent of the patients had had craniotomies. The case records were collected from 1935-1944. The locations of these tumors are presented in Table 2. Their typing, following the customary outline of Cushing,<sup>7</sup> is presented in Table 3. The preponderance of malignant types reflects the fact that many of the cases were chosen from post-mortem files. Thus, this study is not characteristic of brain tumors as the neurosurgeon sees them but of patients with brain tumors who die. This actually represents patients in whom the process was more severe and in whom

TABLE 3 Types of Tumors

TUMOR	No. of Cases
Glioblastoma	46
Astrocytoma	12
Meningioma	11
Spongioblastoma (polare)	7
Craniopharyngioma	5
Chromophobe adenoma	3
Ependymoma	3
Medulloblastoma	3

the symptoms were therefore probably more striking.

Diagnoses of the Community

Relatively little information was obtained regarding diagnoses by friends or relatives. It is of interest, however, that of the 16 recorded diagnoses, personality disorders were mentioned in 10 cases and that 2 others were considered alcoholism because of the patients' drunken gait. Eye trouble was diagnosed in 2 cases, and epilepsy in one, and a chiropractor made 1 diagnosis of "misplaced axis."

Such diagnoses undoubtedly reflect to some degree the popular interest in nervous disorders and the opinion of many lay people that they are competent to diagnose and prescribe for such difficulties themselves.

### *Diagnoses by Family Physicians*

About half the patients left their physicians presumably dissatisfied with the unsuccessful treatment and lack of diagnosis. The other half were eventually referred to hospitals because of "serious disease" requiring more careful and specialized study. The survey of these diagnoses is given in Table 4. Only 4 per cent correct diagnoses and 2 per cent doubtful diagnoses of brain tumor were made. It is interesting that patients reached specialists in most cases only after having been investigated by internists, surgeons, ophthalmologists and so forth, and in no case were they referred directly by general practitioners in the community.

TABLE 4 *Diagnoses by Medical Practitioners in the Community*

DIAGNOSIS	No of Cases
'Nothing wrong'	20
Emotional disorder (neurosis)	12
Epilepsy	5
Eye disease	5
Brain tumor	2

Appendicitis	1
Sinusitis	1
Facial palsy	1
Anemia	1
Psychosis	1
Rheumatic fever	1
Encephalitis	1
Neuralgia	1
Optic atrophy	1
Head injury	1

The low percentage of correct diagnoses may also have been influenced by the social group. The lay group tends to evaluate any deviation from the normal in terms of nonconformity with accepted patterns of behavior rather than in medical or physical terms.

### *Diagnoses Made in Hospitals by Nonspecialists*

These diagnoses are given in Table 5. The percentage of correct diagnoses has increased considerably, being correct in 29 and at least considered in 8 additional cases. The diagnosis of personality disorder is still high, however (pschoneurosis, 13 cases, and psychosis, 2 cases), and 11 cases were listed as "no diagnosis." It is probable that in the last group there were many patients who were believed by the examining physicians to be psychoneurotic but on whom they were unwilling to make a definite statement. The diagnosis of epilepsy is still considered in an impressive number of patients.

### *Diagnoses Made by Neurologists, Psychiatrists and Neurosurgeons in Hospitals*

Of the 100 patients 94 were seen by specialists, and in all but 7 cases the correct diagnosis of brain tumor was made. The signs observed on neuro-

diagnosis. In 49 patients a correct localization was made, and in 28 patients a correct clinical diagnosis of the histologic type of tumor was made. Three cases in which diagnoses were missed by specialists are briefly reported below.

CASE 1 (A75793) A 72-year-old laborer entered the emergency room with a history of having "fainted" while descending the stairs and of having consequently struck his head and left arm. He also stated he had been treated by his family physician for years for a heart condition.

Physical examination was reported negative except for swelling of the left wrist, abrasion of the left side of the

face and head and auricular fibrillation and cardiac enlargement. X-ray study revealed a Colles fracture of the left wrist and a fracture of the left parietal bone. The patient was treated and discharged 12 days later.

After 3 weeks he was readmitted to the hospital because he had an episode of vomiting at midnight followed by a stool containing bright-red blood. Physical examination was essentially negative except for his cardiac status and the fact that he was noted to be "senile", the fundi were "not well visualized." A positive Romberg test was noted. The diagnostic considerations were mainly concerned with the rectum.

Thirty-three days after admission the patient was observed one night to have a sudden drop in blood pressure. He perspired profusely, and yet the pulse remained full and strong, no temperature changes were noted. It was assumed that he had had a large hemorrhage into his bowel. The next morning he was observed to have a right-sided hemiparesis, a bilateral positive Hoffmann sign, right positive Babinski sign, absent superficial reflexes and drooping of the right corner of the mouth. The diagnostic assumption was that he had a cerebral hemorrhage. No lumbar puncture, electroencephalogram or air study was done. The patient's course was rapidly downhill, and he died 3 days later.

The post-mortem findings were meningioma, compressing the right motor strip, generalized arteriosclerosis with multiple hemorrhages in the small bowel and cardiac hypertrophy.

**CASE 2 (A53451)** A 58-year-old housewife was first seen in the psychiatric inpatient service on March 7, 1935. The past history revealed that approximately 3 years previously she had noted a progressive failing of vision. Two years before admission tinnitus developed, and her appetite was no longer as good as it had been. Approximately 6 months later a left frontal headache developed, which was intermittent, and she began to fear being alone. This was followed by an attack of severe headache accompanied by nausea and vomiting and by several days of depression. She gradually became forgetful and depressed, and had some difficulty in speaking. At about this time her friends noticed personality changes, and two physicians believed that her difficulty was not organic. Six months later her vision became much worse and she was again seen by two physicians, one of whom made no diagnosis, and the other of whom treated her tinnitus with "electricity." Her speech became worse, and on consulting another physician she was referred to the psychiatric inpatient service.

On admission the provisional diagnosis was cerebral arteriosclerosis with encephalopathy. The positive neurologic signs were weakness of the right facial nerve, hyperactive deep tendon reflexes on the right, apraxia and a questionable right homonymous field defect. This was confirmed by neurologic consultation. Lumbar puncture disclosed a spinal-fluid pressure equivalent to 195 mm of water, varying up to 235 mm. No other laboratory studies were done except for routine blood and urine examinations.

The patient died 2 days after admission.

Post-mortem examination revealed a glioblastoma multiforme involving the left temporoparietal lobe.

**CASE 3 (A70941)** A 19-year-old boy was first admitted to New Haven Hospital (neurosurgical service) on August 13, 1942, because of severe frontal and occipital headaches on June 28. These were severe in the early morning, disappearing about 10 a.m. They became progressively worse, and nausea and vomiting appeared after 2 weeks. He complained of transient dizziness but no true vertigo. He had received his draft classification on June 30. The past history was otherwise irrelevant.

Physical examination was entirely negative, including neurologic examination, with the exception that he "staggered in all directions on walking." The diagnostic impression was "hysteria." The patient was noted to be of "low intelligence."

Lumbar puncture on the day after admission showed an initial spinal-fluid pressure equivalent to 110 mm of water, with a protein of 82 mg per 100 cc. On August 17 no pressure was noted, the protein was 42.5 mg per 100 cc.

The patient was to have a skull x-ray film but this procedure was not done. He was discharged on August 17 with a diagnosis of hysteria. He was seen 1 month later in

the clinic and at this time his symptoms were still present, and the diagnosis was the same, he was referred to the psychiatric outpatient clinic.

The patient was followed in the psychiatric outpatient clinic until November 10, when his symptoms became exacerbated and he was admitted to the psychiatric service. At this time he was described as being stuporous, dehydrated and acutely ill. He had cervical rigidity, suboccipital tenderness and a positive Kernig sign on the right. The pupils were dilated, the left one being sluggish to light. Bilateral papilledema (4 diopters), with hemorrhages, was noted. Dysarthria, left-facial-nerve weakness and bilateral ankle clonus were present.

Lumbar puncture on admission showed an initial spinal fluid pressure equivalent to 350 mm of water, with a total protein of 30 mg per 100 cc. The diagnosis of an expansive lesion of the brain was made. The patient died on the night of admission.

Post-mortem examination on November 11 disclosed sarcoma of the left cerebellar hemisphere, with extension into the dura and fourth ventricle, atrophy of the sella and inner table of calvarium and a cerebellar pressure cone.

## DIAGNOSTIC CONTRIBUTIONS OF LABORATORY TECHNIQUES

### *Cerebrospinal Fluid*

Lumbar punctures were recorded on only 41 of the 100 patients. In 38 cases the cerebrospinal fluid was abnormal, and the test confirmatory. In 36, the pressure was over 180 mm of water. The total protein was above 50 mg per 100 cc in 24 patients. In 5 cases no attention was paid to the abnormal spinal-fluid findings, and thus a very important clue to the diagnosis of brain tumor was missed.

### *Radiologic Examination of the Skull*

In 91 patients x-ray films of the skull were taken. This probably reflects the ease of ordering skull films and the prominence of radiologic diagnosis in general medical thinking. In contrast to the high percentage of positive spinal-fluid findings, however, pathologic findings were noted in only 48 cases. In only 2 cases did the x-ray examination lead to erroneous localization.

### *Electroencephalogram*

Since many patients were examined before the electroencephalic laboratory was organized, electroencephalic reports were available in only 21 patients, 19 of these were abnormal, indicating a significant contribution to diagnosis. In 10 of these patients the lesion was localized by the electroencephalogram.

### *Ventriculogram*

Ventriculograms were performed in 33 patients. Localization was correct in 27 cases — a significant proportion. In 2 patients the localization was false.

## DELAYS IN DIAGNOSIS

The number of months elapsing between the first time when a diagnosis seemed possible and the moment of correct diagnosis was estimated. The mean of such delay was fifteen months, the median twenty-four, and the longest interval eighteen years.

In a third of all patients, the time loss was less than three months, however, and in half the cases the time loss was less than one year. Because the delay in the more malignant groups is necessarily low, the time loss in the less malignant tumors seems even more striking.

Diagnostic errors made during the period of hospitalization are presented in Table 7. In some of these cases the correct diagnosis was missed owing to a combination of errors. For example, under the heading of inadequate neurologic examination, both lack of a reasonably thorough examination and a gross lack of interpretation of positive neurologic signs are included.

### DISCUSSION

In about half the patients the diagnosis of brain tumor was seriously delayed (over one year). In almost a fourth of these patients the delay was more than two years. Much of this was due to ignorance and inertia on the part of the patients' families, who did not consult a physician. On the other hand, of course, it is a common experience of many psychiatrists to see patients suffering from fatigue, giddiness and mild headaches who hypothetically assume the diagnosis of brain tumor. On the basis of knowledge of initial signs and symptoms it should be possible to stress the need for medical examination in the presence of headaches, visual impairment and giddiness accompanied by nausea. Education along this line need not remark on the possibility of brain tumor, but only on the necessity for seeking medical advice.

The low percentage of correct diagnoses of brain tumors by general practitioners in the community is striking. This is offset by the fact that about half the patients in whom no appreciable time loss in diagnosis occurred (a sixth of all patients) went through the hands of physicians in the community. An even higher percentage of the total number of patients was referred to hospitals or to other specialists with the diagnostic assumption by the general practitioner of a severe illness requiring more thorough diagnostic study.

In the face of these referrals the question arises why the diagnosis of brain tumor is missed at this early stage. Is this due to unawareness of the signs and symptoms of brain tumor, or to failure to carry out necessary examinations? It is our impression that the most important considerations are pressure of time and certain characteristics of a general medical practice that lead to errors or to omissions. One factor determining this may be the reluctance of physicians practicing in certain social groups to diagnose such illnesses as tumors because of the tendency of patients to blame the physician for the consequences of the disease. This also holds for such diagnoses as "tuberculosis" and "mental illness." More important, however, is the probability that many more correct diagnoses

could have been made if a cursory neurologic examination aimed at the detection of muscular weakness, reflex changes and visual symptoms and signs had been performed. The most important of these is an ophthalmoscopic examination. The question then is, Why do general practitioners not carry out such neurologic examinations including ophthalmoscopy? The following possible factors suggest themselves: insufficient emphasis in medical training on important practical steps in diagnosis and treatment, such as the carrying out of a brief "emergency neurologic examination"; insufficient reward in the way of positive findings seems to result in the abandonment of such special examinations as

TABLE 7 Survey of Diagnostic Errors in Hospitals

Error	No of Cases
Inadequate neurologic history and examination	27
False evaluation of personality disorder	15
Seizures not explored	14
Headaches not evaluated	8
Failure to evaluate visual symptoms	6
Failure to evaluate cerebrospinal-fluid findings	5
Insufficient laboratory work	5
History of head injury overevaluated	4
Overevaluation of hypertension	4
Assumption of degenerative brain disease based on insufficient evidence	4
Examiner sidetracked by medical symptoms (elevated temperature, glycosuria, hyperthyroidism)	3
Overevaluation of alcoholic history	2
Coma not investigated	1
Deafness not investigated	1
Too great dependence on negative laboratory findings	1

ophthalmoscopy by general practitioners — this may explain to some degree why general practices are often considered dull in terms of detection and treatment of rare diseases, the tendency to attribute symptoms to minor neurotic difficulties is strikingly dramatized by the diagnosis of "nothing wrong" in 20 of the 49 diagnoses made by local practitioners and of a personality difficulty in 12 cases. The proportion so diagnosed (51 per cent) was markedly reduced by the nonspecialists' diagnoses made in hospitals (24 per cent). Since a review of early complaints reveals psychiatric and neurologic symptoms or intellectual deficit in 41 patients, the error obviously consists not in assuming personality disorders when they are absent but in neglecting to find the proper cause for such disorders. The simple device of looking for behavioral disorder and organic signs and then correlating both should help to avoid this frequent error.

Hospital physicians have the advantage of observing changes in the patient over a period and in addition, early technics for refined diagnoses are more available. Still, inadequate neurologic examinations and false interpretations of data were very important causes of errors. The lack of investigation of seizures was noteworthy. Symptoms such as these, as well as headaches and visual impairment, were often easily assumed to be due to hypertensive encephalopathy, cerebral arterio-

sclerosis and various progressive degenerative brain diseases

Compared with other groups, the percentage of correct diagnoses made by specialists (neurologists, neuropsychiatrists and particularly neurosurgeons) was high. This demonstrates that available technics and knowledge permit a high degree of diagnostic acumen. On the other hand, it must not be overlooked that previous spade work helps greatly to eliminate errors, and, in addition, it is always easier to diagnose tumors in later stages than at the onset.

Laboratory procedures appeared to have mostly confirmatory value rather than to be useful as independent diagnostic technics. Clinical findings seem to be of primary importance. The early use of radiologic and electroencephalographic technics, however, is highly recommended, and it is our impression that the electroencephalogram is by no means as frequently used as it should be. Lumbar puncture in persons suspected of having tumors seems best reserved for hospital practice. The possible development of a pressure cone, particularly in posterior-fossa tumors, should be seriously considered. Air studies in most cases are late studies to establish localization and should be done only by neurosurgeons equipped to follow through with operation if necessary.

On the basis of the above material, a recommendation for better mass health education regarding early symptoms of dangerous disease—in this case, of tumors and particularly of brain tumors—seems justified. This is an exceedingly delicate problem, however, and a great deal of thought is necessary to spread knowledge on a mature, realistic level without increasing general hypochondriacal concern. Possible agencies of communication are biology classes in school, health drives, appropriate literature and radio talks.

At the level of the physician, teaching of abbreviated neurologic examinations in medical schools and hospitals might decrease the incidence of error and delay in the diagnosis of brain tumor. The principle of appropriate referral to specialists when the practitioner is unable to carry out the necessary examinations needs a more liberal and intelligent interpretation. Attention should be drawn to statistical tables demonstrating early signs and symptoms. Certain general diagnostic procedures—

for example, ophthalmoscopy—seem so basic that they should not be abandoned even under the pressure of a busy practice, or if negative findings are obtained in an overwhelming number of cases. Such frequent diagnostic errors as failure to explore seizures, headaches and visual impairment, failure to examine for changes in the fundi, slight muscular weaknesses and reflex changes can be avoided. Personality changes should be explored from both an organic and a behavioral point of view and should not be used in themselves as an excuse for cessation of further organic or behavioral investigation. Results of laboratory procedures should be used and interpreted within the context of the total clinical situation. Thus, achievements so far the prerogative of the specialist will find a wider and more useful application in the field of general medical practice.

### SUMMARY

A study of 100 proved cases of brain tumor revealed that in approximately half the cases the diagnosis was delayed for a year or longer. Although social and psychologic factors often delayed referral by the family to a physician, the low percentage of correct diagnoses by practitioners in the community was striking. The failure of the practitioner to carry out routine brief neurologic examination and a tendency to attribute symptoms to personality difficulties with subsequent lack of further investigation seem important. A standard survey of early signs and symptoms and errors due to overlooking or ignoring of such findings is made. The value of specific clinical and laboratory studies is assessed. Public-health education designed to avoid such delays in diagnosis is indicated at both lay and professional levels.

## THE EFFECT OF SUBACUTE BACTERIAL ENDOCARDITIS ON THE COURSE OF THE UNDERLYING HEART DISEASE\*

BERNARD RAPOFORT, M D,<sup>†</sup> AND LAURENCE B ELLIS, M D<sup>‡</sup>

BOSTON

THE development of a successful treatment for subacute bacterial endocarditis by penicillin has greatly changed the significance of this condition as an event in the life history of a person with chronic heart disease. Formerly, the disease was almost universally fatal, with the infection itself dominating the clinical picture, and therefore it was of relatively little moment whether heart failure developed or not. Now, since the infection can usually be controlled, if increased cardiac damage occurs it may materially increase the disability or lead to early death of the patient from heart failure. Many of the investigators<sup>1-12</sup> who have reported the results of the penicillin treatment of patients with subacute bacterial endocarditis have emphasized both the importance of heart failure or acute cardiac accidents as a factor in a fatal outcome during treatment, and the development of increased cardiac disability following successful arrest of the infection. It is not apparent in most of the reports to what extent decreased cardiac reserve was present in patients before the infection developed or treatment was begun. Fiese,<sup>11</sup> however, made a careful study of the factors responsible for cardiac failure developing after treatment and concluded that this condition is the result of a number of factors, no one of which is exclusively responsible. The most important are the previous reserve and size of the heart, the patient's age, the type of lesion of the heart, the height of the temperature, the general clinical appearance, and the length of time before adequate treatment. Jones et al.<sup>12</sup> have reported a detailed follow-up study. These authors found that although the patients who recovered claimed no subjective increase in disability they often presented objective evidence of increased cardiac damage as evidenced by progressive cardiac enlargement. When the data are given in the case reports of these and other authors it is evident that heart failure developed a few weeks after the conclusion of treatment.

The purpose of the present study was to assess the late results of subacute bacterial endocarditis on the cardiac status of patients. Hence we selected

a group of patients who were treated a minimum of two years before the follow-up studies.

### MATERIAL

The material for this report consists of 15 patients with subacute bacterial endocarditis caused by alpha-hemolytic streptococcus who were treated at the Boston City Hospital during 1944 and 1945, and comprises the total number of such cases seen at the institution during this period satisfying the following criteria. Cases were accepted that had at least two positive blood cultures for *Streptococcus viridans* and had clinical evidence of valvular heart disease. All but one of the patients gave evidence of peripheral emboli. Four of the 15 patients have died, and the diagnosis of subacute bacterial endocarditis was confirmed in each case by post-mortem examination. All the living patients were re-examined two years or later after their original infection by one of us (B R.) in June, 1947. Complete blood counts, urinalyses and blood cultures were done, and teleroentgenograms of the heart and electrocardiograms were taken. The relevant findings are shown in Tables 1 and 2.

### Age and Sex

There were 5 male and 10 female patients. The ages ranged from nineteen to sixty years. Of the 4 patients who died, 2 were men aged forty-nine and fifty-three, and 2 were women aged twenty and twenty-one.

### Etiology of Heart Disease

In all cases the clinical diagnosis was chronic rheumatic heart disease. This was confirmed at autopsy in the 4 fatal cases. In 8 of the 15 patients no preceding history of rheumatic fever could be obtained, in the remainder there were definite histories of rheumatic fever.

### Valvular Involvement

In the 11 living patients evidence of involvement was limited to the mitral valve in 7 cases, and in the other 4 there was evidence of disease of both mitral and aortic valves at the time of treatment for subacute bacterial endocarditis. When follow-up examinations were done, signs of valvular deformities had remained unchanged in all cases. In the fatal cases clinical examination indicated mitral and aortic involvement in 2, and mitral involvement alone in 2. At post-mortem examinations the clinical diagnosis was confirmed in 3, and

in a case suspected clinically of mitral valvular disease alone there was evidence of healed aortic valvulitis of rheumatic etiology as well. The bacterial vegetations involved only the mitral valve in this case.

### Heart Size

The heart size was obtained from 6-foot tele-roentgenograms. Slight changes in serial measurements, which could have been due to altered position of the heart in the chest, were disregarded. The degree of cardiac enlargement was classified

during the infection showed some straightening of the left border of the heart, which was unchanged two years later.

### Rhythm

All the patients in this series had sinus rhythm when admitted for treatment. One (Case 11) developed auricular fibrillation during the active infection and reverted to sinus rhythm on quinidine therapy. Another (Case 3) has developed persistent auricular fibrillation since being cured of his

\*Patient given digitalis

as "none," "moderate" or "marked." There was evidence of marked cardiac enlargement in 3 of the fatal cases when the patients were admitted for treatment of bacterial endocarditis. In the other fatal case no enlargement was noted. In 4 of the 11 living patients there was marked enlargement at the time of treatment, and on follow-up examination the same degree of enlargement was found. Six showed moderate enlargement during their infection, and in 4 of these on the follow-up examination the hearts were normal in size clinically and by x-ray examination, and 2 remained unchanged. One patient showed no definite cardiac enlargement at any time, but x-ray examination

endocarditis, and his rate has been well controlled on digitalis therapy.

### Electrocardiographic Findings

The results of comparison of electrocardiograms recorded at the start of treatment for bacterial endocarditis and those taken on follow-up study are presented in Table 1. Records were available for comparison on all patients who survived except 1 (Case 5). In 8 cases there was no significant change. One patient developed auricular fibrillation, and in one the T waves in Leads 1 and 2 became inverted.

*Cardiac Reserve*

In Table 1 the functional capacity in each case is shown before, during and two to three years after the infection, rated in accordance with the classification of the American Heart Association<sup>13</sup> In 3 living patients (Cases 9, 10 and 11) there was clinical evidence of decrease in cardiac reserve occurring during the febrile illness, and in 1 of these the transient auricular fibrillation occurred In another patient (Case 10), in whom signs of cardiac decompensation were most marked and required

physical signs of congestive heart failure She was improved by digitalis and has continued on it, leading a fairly active life and working twenty hours a week as a saleswoman in a department store

All 11 patients, when examined in June, 1947, reported themselves to be at least as well as they had been before their illness They were all as active as they had been in the years immediately prior to their subacute bacterial endocarditis, and in some cases stated that they could do more than they had been able to do before their illness In

vigorous therapy with oxygen and digitalis, the heart failure was precipitated by the combination of the infection and the pregnant state, since her infection and her heart failure became manifest in the early puerperium All 3 of these patients improved after treatment to a point where their cardiac reserve was as good as that before the infection developed

One patient who did not develop any signs or symptoms of heart failure during treatment for endocarditis was started on digitalis therapy about ten months later because of the complaint of dyspnea although the degree of shortness of breath had not increased At this time there were no

none of these patients were there any clinical or urinary findings suggesting chronic renal disease

It will be noted that there was a diminution in cardiac reserve in 3 of the fatal cases associated with the infection and that in the fourth case no change was noted In 3 of these cases there was evidence of persistent active bacterial infection at autopsy, and thus they represent failures in the treatment of the infection One patient (Case 15) who developed the most marked cardiac failure during her infection, was cured of the infection and died of a coronary embolus eight months after the eradication of the infection During this period she remained in severe heart failure, requiring digi-

tal and frequent mercurial diuretics. The case history of this patient is as follows:

A 20-year-old woman was first admitted to the hospital on June 16, 1945, with a history of chills, fever and headache of 11 days' duration and a history of a known heart murmur for 4 years. There was no history of rheumatic fever or cardiac disability. She was found on this admission to have a meningococcal (Group I) infection of the blood and spinal fluid. She was successfully treated with sulfadiazine and penicillin, with rapid improvement and was discharged as cured after 8 hospital days. Cardiac examination during this admission showed a heart that was enlarged, the border of cardiac dullness extending to the left anterior axillary line, and there was a loud, harsh apical systolic murmur. There was no evidence of cardiac decompensation.

She was readmitted to the hospital 5 months later, with a 2-month history of night sweats, anorexia and malaise and a 3-week history of cough and some dyspnea on exertion. On entry she was febrile, no petechiae were noted on the skin, and the lungs were clear. The heart was enlarged, with a

present, and there was a moderately loud apical presystolic murmur. A moderately loud systolic murmur was heard in the aortic area. The liver edge was palpable six fingerbreadths below the costal margin. There was minimal clubbing of the fingers, no pitting edema was noted. The patient failed to respond to therapy and died a few hours after admission.

At autopsy on the following day the heart appeared grossly enlarged, weighing 450 gm., and the left auricle was moderately dilated. The epicardium was not remarkable, and the endocardium was not remarkable except for the left auricle and the mitral valve. On the wall of the auricle there were many somewhat orange-tinged plaques of elevation, which were glairy in appearance and seemed to be part and parcel of the auricular wall. On the margin of the aortic cusp of the mitral valve, which was somewhat thickened, there were many yellowish irregular glistening masses, and three or four of the chordae tendineae enmeshed in these masses seemed to have been ruptured and healed on the surface. Lodged in the orifice of the right coronary artery there was a mass of material resembling the vegetations on the mitral valve. This completely occluded the orifice, and distally the artery was filled with a recent thrombus. The

15	12 wk.	6 080 000	25	Intermittent intramuscular	Patient dead

rapid regular rhythm, the sounds were of good quality, and there was a loud apical systolic murmur with a palpable thrill. The spleen was palpable. There was minimal pitting edema of both ankles, and questionable clubbing of the fingers. Roentgenographic examination of the chest showed cardiac enlargement and congestive changes in both lung fields. Three positive blood cultures for *S. viridans* were obtained, and 2 days after admission petechiae were noted in the left conjunctiva and a diastolic murmur was heard at the apex. Treatment with penicillin (30,000 units intramuscularly every 3 hours) was begun on December 3, and continued until December 28. No positive blood cultures were obtained after December 3, and the temperature remained normal after discontinuation of therapy. However, tachycardia persisted and because of persistent signs of cardiac decompensation, digitalis and diuretic therapy was begun. The patient remained in the hospital until February 13, 1946, when she was discharged home still showing signs of cardiac failure. She remained home under the care of a private physician in chronic heart failure until 6 months after discharge, when she was readmitted to the hospital complaining of chilly sensations and an acute severe knifelike substernal pain radiating through to the back and aggravated by respiration.

Physical examination revealed her to be cyanotic, and the extremities were mottled, blue and cold, no pulses could be obtained in the feet, and the radial pulses were rapid and thready. The lungs were clear, the heart was enlarged, the border of cardiac dullness extending to the anterior axillary line in the fifth left interspace, the rate was 100, and the rhythm was irregular, a loud apical systolic murmur was

remainder of the valves and the left coronary artery were not remarkable. There was an area in the center of the base of the interventricular septum that appeared to be slightly yellowish red and mottled. Microscopically, the endocardium of the left auricle showed regions of subendocardial fibrous thickening. The myocardium disclosed focal fibrosis, most marked in perivascular locations. A section from the center of the interventricular septum demonstrated more marked fibrosis than in the ventricular wall, and a section from near the septum at the junction of the left auricle and left ventricle showed areas of polymorphonuclear-leukocyte infiltration between the muscle fibers. Culture from the mitral valve was negative for streptococcus with alpha hemolysis. The final pathological diagnoses were rheumatic heart disease, old, with mitral insufficiency, cardiomegaly, myocardial fibrosis, healed bacterial endocarditis, with rupture of chordae tendineae of the mitral valve, vegetations on mitral valve, embolus in orifice of right coronary, with myocardial infarction, healed infarcts in spleen and kidney, focal embolic glomerulonephritis, healed, chronic passive congestion of liver, spleen, kidneys and gastrointestinal tract, ascites, and bilateral hydrothorax.

#### Cardiac Status

In 5 cases data were available to permit some comparison of the cardiac status before the development of the bacterial endocarditis with later findings. One patient (Case 15) had developed

progressive cardiac failure after cure of the infection and died of a coronary embolus eight months later. In this case the marked enlargement of the heart and harsh apical systolic murmur, which was present when treatment was started, had also been noted five months earlier. In the 4 other cases (Cases 3, 4, 7 and 9) the cardiac findings noted at the time of admission with the bacterial infection had been present in the same degree on previous examinations made two, six, ten, and five years earlier respectively.

### Treatment

Table 2 contains a summary of the treatment with penicillin in all cases. Several of these cases have previously been reported.<sup>14</sup> These patients were treated when penicillin supplies were scarce, and the dosages were somewhat lower than those used in the treatment of this disease at present. In most cases the daily dose was between 200,000 and 300,000 units of penicillin.

### Discussion

Subacute bacterial endocarditis can increase cardiac damage in spite of cure of the infection either by causing rupture of a valve cusp or of chordae tendineae, or by the later scarring and distortion of the valves resulting from the healing and absorption of vegetations producing increased mechanical inefficiency of the heart. The effects may be severe, with rapidly developing heart failure, especially when there is great destruction of a valve.<sup>1, 2, 12</sup> Such failure develops during or soon after the active infection. Several observers have commented on the development of failure of this type particularly when the aortic valve is involved.<sup>6, 14</sup> The late development of a diminished cardiac reserve is in many cases related to the scarring process.

Heart damage accompanying subacute bacterial endocarditis may also be produced by acute myocardial lesions. It has been observed that the hearts of patients dying of subacute bacterial endocarditis very commonly show histologic evidence of myocarditis, especially small infarcts<sup>15</sup> due to minute coronary emboli.<sup>16</sup> Such lesions may well be an important factor in heart failure developing during or shortly after the active infection, and the myocardial fibrosis that may follow could be a contributory element in a later decrease in cardiac reserve.

In our series there was no correlation between the development of cardiac failure and the age of the patient or the length of time the infection had persisted prior to the successful treatment. This is shown most obviously in the 2 patients with relapses, who had recurrent and probably persistent active endocarditis for more than twenty-four and fourteen months. One of the patients (Case 8) was sixty years old, and his heart was actually smaller two years after his cure. The other (Case 7)

had cardiac enlargement with free aortic regurgitation when he first came under observation, which had not demonstrably changed nearly three years later.

### SUMMARY

Fifteen cases of subacute bacterial endocarditis caused by streptococcus with alpha hemolysis, which were treated in 1944 and 1945 and re-examined in June, 1947, at least 2 years after the original infection, are reported.

Eleven patients were living and well. Subjectively they all felt as well as they had prior to their infection. In 4 patients the cardiac size decreased after cure of the infection, in the other 7 there was no change. One had developed auricular fibrillation, and another has been taking digitalis for dyspnea although it is not clear that her condition has changed materially. In another patient the electrocardiogram showed evidence suggesting an increase in myocardial damage. These changes could as well have been due to the inevitable course of rheumatic heart disease in general as to any specific effect of the bacterial endocarditis.

Four patients in the group had died and were autopsied. In 3 there was post-mortem evidence of persistent active infection. One patient died in spite of eradication of the infection. Death in this case was due to a coronary embolus, but the patient had been in chronic congestive failure since cure of the infection.

## GENERALIZED BULLOUS ERUPTION FOLLOWING TESTING FOR SULFONAMIDE HYPERSENSITIVITY\*

DAVID A. STRAUS, M.D.†

CHAMBLEE, GEORGIA

**E**RYTHEMA multiforme exudativum is a well recognized clinical entity, but despite extensive investigation its etiology is obscure.<sup>1-4</sup> Eruptions due to drug idiosyncrasy, which are compatible with the clinical picture of erythema multiforme exudativum, are not uncommon and have frequently been described.<sup>5-12</sup> The sulfonamides are among the drugs that have been incriminated<sup>5-9</sup>

observed phenomena reproduced the picture of erythema multiforme exudativum, it is thought desirable to call attention to the reaction.

### CASE REPORT

J. W., a 31-year-old Negro sawmill laborer, had a history of having received in 1943 a course of antisyphilitic therapy consisting of 19 intravenous injections of an arsenical and 20 intramuscular injections of a bismuth com-

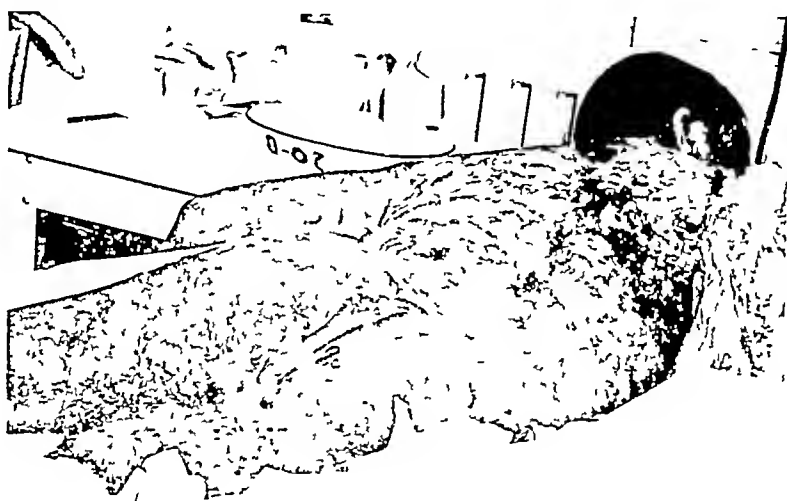

FIGURE 1 Site of the Bullous Eruption Where Most of the Bullae Had Ruptured, Leaving a Raw Granulating Surface

There is no real agreement, however, regarding whether such an eruption, although morphologically and clinically indistinguishable from the idiopathic erythema multiforme exudativum, should be classified as truly part of the syndrome.<sup>2-4</sup> Regardless of how this drug reaction is classified, the importance of establishing or excluding the sulfonamides as etiologic agents when the possibility of their future therapeutic use is considered can easily be appreciated.

Recently, a patient whose clinical course fulfilled the criteria of erythema multiforme exudativum was observed. In an attempt to establish the etiology of the syndrome the passive transfer test, as described by Leftwich,<sup>13</sup> was used. Because an atypical and severe reaction ensued after what is usually regarded as a benign test and because the

pound. In 1945 there was a history of his being seen in a public-health center, where diagnoses of "early latent syphilis" and "erythema multiforme" were made and he was given 1,200,000 units of penicillin, 300 mg of arsenoxide and 60 mg of bismuth subsalicylate during a 10-day period. Nothing further could be learned about his condition at that time. On December 2, 1947, he was admitted to a state venereal-disease-treatment center with a penile ulcer of 1 year's duration and a pruritic rash between his toes. Negative serologic tests for syphilis were obtained from the blood and spinal fluid, and diagnoses of "chancroid" and "scabies" were made. He was given sulfathiazole orally and treated with an "antiscabetic routine"—the medication used in the latter was not ascertained. Two days later, after having received 2 gm of sulfathiazole, he had an epileptiform convulsion, and the temperature rose to 103.8°F. (It was learned subsequently that he had had similar convulsive seizures about twice yearly since a head injury incurred at the age of 14.) The temperature remained elevated, and on the next day, ulcerated lesions appeared on the mucous membranes of the mouth. The sulfathiazole was discontinued. On the following day, flaccid bullae appeared on the extremities, and on the next day, on the eyelids, buttocks, penis and scrotum. He was given 300,000 units of penicillin in oil and beeswax daily, as well as intravenous fluids. He was transferred to Lawson Veterans Administration Hospital on December 28, 1947, with the diagnosis of "pemphigus."

Physical examination showed an acutely and severely ill patient. Swallowing was painful, and was possible only with liquids. The mucous membranes of the mouth and lips were

†Resident in medicine, Lawson Veterans Administration Hospital.

raw and bleeding, and there were numerous, small bullae on the tongue. There were marked scleral injection and chemosis and a moderate amount of milk conjunctival suppuration. A few coarse inspiratory and expiratory rhonchi were heard scattered throughout the lung fields which were otherwise normal. The skin of the entire body exhibited numerous bullae. These were varied in size, but most were of the size and shape of Brazil nuts. They were located superficially in the skin and most of them had been ruptured and part of the clear serous fluid evacuated, leaving a thin, loose membrane over their surface and giving the bullae a flaccid appearance. The surface skin of many of the bullae was absent, leaving a red, granulating, moist area (Fig 1). There was no inflammatory reaction surrounding the bullae. The face was clear except for a bullous eruption on the upper eyelids and ears and the lip lesions described above. The entire surface of the palms and soles was covered by a large bullous formation (Fig 2). The patient exhibited a balanitis, and there were small, denuded areas on the penis and scrotum (Fig 3). There was a moderate, generalized lymphadenopathy. The spleen was not palpable.

The temperature was 101.2°F, the pulse 96, the blood pressure 100/50, and the respirations rapid, shallow and grunting.

Examination of the blood disclosed a hemoglobin of 15 gm (Alett method) and a white-cell count of 7450, with 58 per cent neutrophils, 36 per cent lymphocytes, 1 per cent monocytes and 5 per cent eosinophils. Serologic tests for syphilis yielded three "doubtful" Kahn reactions and a negative Wassermann reaction. Urinalysis showed a +++ test for albumin and innumerable erythrocytes in the sediment. The erythrocyte

later, the passive transfer test, after the method described by Leftwich,<sup>12</sup> was performed by the intradermal injection of 0.05 cc. of serum from another patient, who had a sulfadiazine blood level of 7.0 mg per 100 cc. and whose serologic test was negative. There was no reaction, either local or systemic, and the next day the patient was discharged from the hospital. On the day of discharge his face and scalp began to itch, and 3 days later bullae began to appear on his thighs and forearms and then on his eyelids and in his mouth and finally on the rest of his body. He stated that he had taken no medication of any kind.

FIGURE 3 Balanitis and Denuded Areas on the Penis and Scrotum

FIGURE 2 Large Bullous Formation on the Feet, Which Was Even More Extensive over the Soles

sedimentation rate was 31 mm per hour (Wintrobe method). The blood nonprotein nitrogen was 34 mg, and the total serum protein 7.0 gm per 100 cc, with 3.8 gm of albumin and 3.2 gm of globulin. The icteric index was 6, and the thymol turbidity 8.4 units. A culture of the bullous fluid was sterile.

The patient was treated with intramuscular aqueous penicillin and boric acid soaks and ointment locally, saline mouth washes, 10 per cent zinc sulfate solution was instilled in the eyes three times daily. He made a gradual and uneventful recovery, the skin lesions healing without scarring in about 5 weeks and the urine returning to normal.

After he had recovered clinically, he was tested for sulfonamide sensitivity. First, a patch test, consisting of a pulverized sulfathiazole tablet made into a paste by mixture with a small amount of distilled water, was administered to the unbroken skin. The results were negative, and 2 days

since discharge and knew of no contact that could have caused the eruption. On readmission, 1 week after his discharge, his appearance, physical findings and laboratory data were almost identical to those of the previous admission. The same course of treatment was pursued, and again, in approximately 3 weeks, the lesions had healed. Since the relation between the passive transfer intradermal test for sulfadiazine and the eruption, which started 2 days later, was not recognized, he was given a test dose of 0.5 gm of sulfadiazine orally. Within 2 hours he began to have a generalized pruritus, and 3 hours later the temperature rose to 101°F, and he had a shaking chill. Subsequently, he became comfortable and slept for 3 hours, after which he awoke nauseated and vomited intermittently, for 2 hours and, while walking to the lavatory, became giddy and fell to the floor. At this time the respiration became fast and labored, at a rate of 30 per minutes, the pulse was 110 and weak, and the blood pressure was 100/60. He was given 100 mg of pyribenzamine orally four times daily. About 12 hours later he complained of a "skim" over his eyes, and conjunctival injection was noted. At this time, one of the darkly pigmented areas that marked the sites of the bullae of the previous eruption had formed a new bulla. A purulent urethral discharge was also noted, which yielded *Staphylococcus albus* on culture. The temperature rose to 104°F. By the next morning, his skin, mucous membranes and conjunctivas were involved as before, and identical treatment was instituted. Because of the large amount of serum that continued to ooze from the denuded areas, the patient was given transfusions of 500 and 1000 cc. of whole blood on the 3rd and 4th days of the eruption respectively and a pressure dressing over petrolatum-impregnated gauze was applied to the extremities, furacin ointment was applied to the trunk and buttocks because of the development of suppuration. Two weeks after the administration of the oral sulfadiazine, the temperature gradually subsided to normal. The mucous membranes had healed, and conjunctivitis disappeared in 3 more days, the remaining skin lesions had again healed without scarring.

J. W., a 31-year-old Negro sawmill laborer, had a history of having received in 1943 a course of antisyphilitic therapy consisting of 19 intravenous injections of an arsenical and 20 intramuscular injections of a bismuth com-

FIGURE 1 Site of the Bullous Eruption Where Most of the Bullae Had Ruptured, Leaving a Raw Granulating Surface

There is no real agreement, however, regarding whether such an eruption, although morphologically and clinically indistinguishable from the idiopathic erythema multiforme exudativum, should be classified as truly part of the syndrome.<sup>2-4</sup> Regardless of how this drug reaction is classified, the importance of establishing or excluding the sulfonamides as etiologic agents when the possibility of their future therapeutic use is considered can easily be appreciated.

Recently, a patient whose clinical course fulfilled the criteria of erythema multiforme exudativum was observed. In an attempt to establish the etiology of the syndrome the passive transfer test, as described by Leftwich,<sup>13</sup> was used. Because an atypical and severe reaction ensued after what is usually regarded as a benign test and because the

pound. In 1945 there was a history of his being seen in a public-health center, where diagnoses of "early latent syphilis" and "erythema multiforme" were made and he was given 1,200,000 units of penicillin, 300 mg of arsenoxide and 60 mg of bismuth subsalicylate during a 10-day period. Nothing further could be learned about his condition at that time. On December 2, 1947, he was admitted to a state venereal-disease-treatment center with a penile ulcer of 1 year's duration and a pruritic rash between his toes. Negative serologic tests for syphilis were obtained from the blood and spinal fluid, and diagnoses of "chancroid" and "scabies" were made. He was given sulfathiazole orally and treated with an "antiscabetic routine"—the medication used in the latter was not ascertained. Two days later, after having received 2 gm of sulfathiazole, he had an epileptiform convulsion, and the temperature rose to 103.8°F. (It was learned subsequently that he had had similar convulsive seizures about twice yearly since a head injury incurred at the age of 14.) The temperature remained elevated, and on the next day, ulcerated lesions appeared on the mucous membranes of the mouth. The sulfathiazole was discontinued. On the following day, flaccid bullae appeared on the extremities, and on the next day, on the eyelids, buttocks, penis and scrotum. He was given 300,000 units of penicillin in oil and beeswax daily, as well as intravenous fluids. He was transferred to Lawson Veterans Administration Hospital on December 28, 1947, with the diagnosis of "pemphigus".

Physical examination showed an acutely and severely ill patient. Swallowing was painful, and was possible only with liquids. The mucous membranes of the mouth and lips were

## FERTILITY STUDIES IN THE HUMAN MALE WITH TRAUMATIC INJURIES OF THE SPINAL CORD AND CAUDA EQUINA\*

HERBERT W. HORNE, M.D.,† CAPTAIN DAVID P. PAULL, MC, AUS,‡ AND DONALD MUNRO, M.D.§  
BOSTON AND FRAMINGHAM, MASSACHUSETTS

**H**UMAN males who have suffered traumatic injuries of the spinal cord and cauda equina have long been considered sterile. This study was performed to determine whether or not this assumption is true. A previous paper<sup>1</sup> discussed the incidence of erection and ejaculation in the human male with traumatic injuries of the spinal cord and cauda equina.

The 18 cases studied in the present series were patients at Cushing Veterans Administration Hospital who had suffered traumatic injuries of the spinal cord and cauda equina. Their ages ranged from twenty-one to thirty-five years, with an average age of twenty-seven years. The length of time that had elapsed since the original spinal-cord or cauda-equina injury ranged from nine to seventy-two months, with an average of forty-seven months. No effort was made to select the cases to be studied, and the only requirements on the part of the patient were that he show consistent interest in the project, that he be voiding without a catheter and that he be in good general physical condition. Many other patients were anxious to be included in the investigation, but time did not permit a larger series.

For the purpose of this paper, the patients are classified as to the level of injury and as to the type of injury. The levels of injury of the spinal cord are reported as dermatome segments. Injuries of the cauda equina are classified separately.

The types of injury are classified in the same manner as that used in the first paper of this series.<sup>1</sup>

Patients diagnosed as suffering from a transection have been divided into two groups, depending upon the accuracy of verification of the diagnosis. In those diagnosed as Anatomic-Visualized Transection (Tr-A) the injury has been actually seen at laminectomy to be one in which there is a complete separation of the cut ends of the cord. In those diagnosed Clinical-Not Visualized Transection (Tr-C) either the cord injury has not been seen or, if seen, the continuity of the cord was found to be either grossly intact or maintained by intervening scar tissue. The character and length of the clinical course taken by the patient, however, have justified the diagnosis of transection. In both instances, only patients with a complete sensory and voluntary motor loss of function below the level of the cord injury are included as cord transections. Patients diagnosed as suffering from a Partial Cord Injury (P) are those in whom it has been

possible to demonstrate some degree of retention of either sensation or voluntary motion, or both, in the body and extremities below the level of maximal cord injury. The same diagnostic criteria have been applied to patients with cauda equina (CE) injuries.

Clinical investigation of these cases included, in addition to routine procedures, evaluation of the external and internal genital organs and the neurologic status. There were no gross changes in the external genitalia except for the cases in which an attack of epididymitis had occurred. In these cases there was invariably a persistent residual induration of the involved epididymis. One patient (Case 7) had a unilateral testicular atrophy secondary to mumps in childhood, and another (Case 1) had a unilateral cryptorchid testis. Virtually all the prostate glands were small, flat, nonnodular and soft.

Semen samples were obtained by electrical stimulation in all cases except 3 (Cases 1, 5 and 18), in which masturbation produced the specimen. A McIntosh No. 5005 portable-wall-plate physiotherapy machine was used to supply the stimulus. This machine delivers predetermined variable amounts of current across a 90-volt potential. The inactive electrode was soaked in tap water and placed under the patient's sacrum with the patient lying on his back. The active electrode was a No. 28 curved urethral sound. This sound was covered with rubber tubing except for the handle and the terminal 5 cm. Electrical stimulation was accomplished by applying sinusoidal and faradic current of 45 and 60 milliamperes, respectively, to the active electrode, which had been introduced into the rectum. The bare tip of the sound was applied successively to the region of each seminal vesicle and the prostate, this sequence being carried out first with sinusoidal, then faradic and, finally, sinusoidal current again. The duration of stimulation in each position was approximately 4 seconds. After withdrawal of the active electrode digital massage successively of the seminal vesicles and the prostate was performed. The semen was then milked from the urethra. No complications, local or otherwise, have followed over 100 treatments of this sort. Massage of the seminal vesicles and prostate without prior electrical stimulation produced fluid devoid of spermatozoa in all but 1 case, when a few spermatozoa were found on one occasion. Electrical stimulation followed by massage produced semen specimens as shown in Table 1. We are frank to state that how or why the electrical stimulation is effective is not clear. Suffice it to say that

## DISCUSSION

Although the patient was able to give no past history of exposure to sulfonamide, the onset of fever followed by the eruption and conjunctivitis, which occurred on the second day (rather than after seven or ten days) of sulfonamide therapy in December, 1947, suggested previous sensitization to the drug. In retrospect, it might be conjectured that the "erythema multiforme" reported from 1945 followed the use of the drug at that time.

There are numerous reports in the literature of cases in which very small doses of a sulfonamide caused severe, generalized skin reactions.<sup>7-14</sup> Cohen, Thomas and Kalisch<sup>14</sup> reported the appearance of a generalized pruritic rash six hours after the local application of 8 mg of sulfathiazole powder, the patient having developed a skin rash two weeks previously, after the use of sulfathiazole ointment locally. Farrington and Wolff<sup>15</sup> described the reproduction of a generalized, oozing, vesicular eruption by simultaneous patch testing with sulfanilamide and sulfathiazole a month after the original eruption, which had been caused by the local use of sulfanilamide. They also described "an intense necrotizing reaction of the buccal mucosa upon application of approximately 8 mg of sulfathiazole to the mouth of a previously sensitized patient" after the method described by Goldman and Goldman.<sup>16</sup> The patient discussed above, on the other hand, showed neither a local nor systemic reaction after application of a patch test of sulfathiazole, although the eruption that appeared in December, 1947, was apparently due to the oral administration of that drug.

Although Leftwich<sup>13</sup> performed 300 intradermal tests for sulfonamide sensitivity, he reported no generalized reactions, and of 30 sensitive patients, 28 had positive tests, the reactions appearing immediately and fading within thirty minutes to an hour and a half. In contrast to these results, the patient in the case reported above showed no immediate or local reaction, but responded to the test by a delayed (twenty-four to forty-eight hours) generalized, severe reaction.

The experience of Farrington and Wolff with the patch test, the reaction with the intradermal passive transfer test and the patch test and the oral test dose discussed above, as well as the reports of others describing severe reactions from small doses of the drug, administered both locally and systemically, have illustrated the potential danger and unreliability of testing for sulfonamide sensitivity. It should be emphasized also that despite reports in the literature describing the treatment of erythema multiforme by sulfonamides, this form of therapy should be used with caution unless one is absolutely certain that the syndrome was not caused itself

by use of the drug.<sup>17-20</sup> This, of course, is true because of the difficulty in clinical differentiation of the bullous eruption sometimes seen in sulfonamide toxicity from idiopathic erythema multiforme.

## SUMMARY

The bullous eruptions that may result from sulfonamide toxicity are often clinically indistinguishable from idiopathic erythema multiforme exudativum. To establish the role of the sulfonamides in an obscure case, several tests for sulfonamide hypersensitivity are available.

A case illustrating the unreliability of the patch test, an untoward and at first unrecognized reaction to the intradermal passive transfer test and a severe reaction following an oral test dose of sulfonamide is reported. It is believed, therefore, that testing for sulfonamide sensitivity should be approached with care, as should the treatment of erythema multiforme exudativum with sulfonamide, as recommended by some, unless it is certain that this drug is not the etiologic agent.

total sperm counts. Patients with injuries to the cauda equina and lumbosacral cord have lower counts in this series, but it is believed that there are not a sufficient number of cases for definite conclusions to be drawn. It is interesting that the patient in Case 13, who had a clinical-not visualized transection at the first lumbar segment, had a normal right testicle by biopsy. This particular patient has had repeated attacks of epididymitis bilaterally, which may well explain the absence of spermatozoa in the semen specimen.

Basal metabolic rates fell, for the most part, within the lower limits of normal. Testicular biopsies in 7 cases varied from complete atrophy of spermatogenic cells to normal testicular activity. The correlation of the spermatozoa counts and the testicular biopsies is reasonably close except in Case 13. The reason for this one aberration is discussed above.

## CONCLUSIONS

Traumatic injury of the spinal cord does not in itself preclude fertility.

A technic is described for obtaining semen specimens from patients having spinal-cord injuries who are unable to ejaculate.

A patient with a clinical-not visualized transection at the fifth thoracic dermatome is capable of erection and ejaculation of normal semen and has successfully impregnated his wife.

We are indebted to Dr Fred A Simmons and Dr George P Denny for their assistance respectively in the sterility and medical aspects of this study.

## MEDICAL PROGRESS

### THORACIC SURGERY (Concluded)

J GORDON SCANNELL, M D \*

BOSTON

#### Results of Treatment

•It is difficult to assess the problem of cancer of the lung in relation to the population as a whole on the basis of reported hospital series. However, it is apparent that in the course of the past ten years, the operability and resectability rates of cancer, as seen by the surgeon, have increased. Björk<sup>70</sup> has reported at length the clinical experience with bronchogenic carcinoma at the Brompton and Royal Cancer hospitals. Of 996 cases in which the clinical diagnosis was made (combining the material of both medical and surgical services from 1937-1944), 15.3 per cent were adjudged suitable for thoracotomy, and 7.5 per cent (or 49 per cent of those explored) were resectable. However, annual operability and resectability rates increased from 8.2 per cent and 5.1 per cent of 134 total cases seen in 1937 to 25.6 per cent and 13.5 per cent, respectively, of 133 cases in 1944. Ochsner, DeBakey and Dixon<sup>71</sup> report that of 360 cases seen on a surgical service between 1936 and 1946, 251 (70 per cent) were considered operable, 210 (58 per cent) were actually explored, and 129 (36 per cent) were resectable. In reviewing the Johns Hopkins series of 327 cases of carcinoma of the lung "referred for surgical

treatment" and presumably explored, Rienhoff<sup>72</sup> reports that 34 per cent were resectable. Thus, of 1950 cases in nine surgical reports since 1940, 782 (40 per cent) were operable and 432 (22 per cent) were resected.<sup>62</sup> By and large, however, these reports represented total experience with the disease and therefore do not reflect changing trends over the years. The importance of defining the material studied in terms of microscopical rather than clinical diagnosis has long since been amply demonstrated (Churchill 1940). Furthermore, the tremendous number of variables, not always apparent in the random selection of clinical material, must be kept in mind.

During the period of increasing limits of operability and of technical standardization, statistics of operative mortality have required almost annual revision downward. The figures of a mere ten years ago are currently of historical interest chiefly. Of more significance as a basis for evaluating present-day surgical therapy are such figures as those of Jones<sup>73</sup>—52 consecutive pneumonectomies, 1942-1946 with 2 deaths (based on a resectability rate of approximately 20 per cent of cases seen)—and of Adams<sup>74</sup>—an operative mortality of 5.1 per cent in 39 resections for carcinoma, 1942-1947 (resectability rate of approximately 30 per cent of cases seen).

\*Instructor in surgery, Harvard Medical School; assistant in surgery, Massachusetts General Hospital.

with electrical stimulation, followed by massage, semen specimens containing spermatozoa have been consistently obtained in 11 of the 18 cases in which simple massage had failed. In each case the first few examinations were not productive of spermatozoa, whereas subsequent trials usually were successful.

Semen analysis was carried out by the technic of Williams and Simmons.<sup>2</sup> In all except Case 5,

in Case 1 has a partial cervical injury and is able to have erections, ejaculations and intercourse in an approximately normal manner. The patient in Case 5 is of particular interest because he has a clinically complete transection of the spinal cord at the sixth thoracic segment. This case was reported in detail in the previous paper.<sup>1</sup> On March 6, 1948, this patient was left alone in a room and asked to obtain a semen specimen. He shortly

semen analyses were carried out on each patient a minimum of three times. The figures stated in Table 1 represent the highest values obtained in each case. Case 5 had one examination only. The chemical determinations, the blood counts and the determinations of basal metabolic rates were done in the hospital laboratory. Reports on seven testicular biopsies were made by the hospital pathologist, Dr. Robert Fienberg, and reviewed by Dr. Fred Simmons.

The wives of the patients in Case 1 and 5 have become pregnant since these patients have returned home from the hospital. The patient

presented a specimen, the analysis of which was as follows:

AMOUNT	TURBIDITY	SPERMATOZOA COUNT	MOTILITY	DIFFERENTIAL
cc		million/cc	26%	
4	++++	115	+ to +++++	Normal 75 Pyn 17 AA 5 Macro 0 Micro 3 Misc 0

## DISCUSSION

In this study there seems to be no striking correlation between the level or type of injury and the

imals, the cases resembled emphysema. The cases of lobectomy showed a similar but less marked deviation from the predicted levels. Maximum breathing capacity, breathing reserve and rate of oxygen utilization were not reported. Of possibly greater significance than the actual laboratory measurements were the estimates of working capacity and dyspnea after the two procedures. In the 12 cases in which pneumonectomies were performed, 9 patients had full working capacity, 2 were unable to work, and 1 was limited to half capacity. All 14 of the patients with lobectomies were reported to have full working capacity. Rienhoff<sup>72</sup> has reported that all his patients except 1 (a professional boxer) who lived any significant time after pneumonectomy for cancer were restored to normal activity. Quantitative measure of rehabilitation of the patient after pneumonectomy is obviously difficult, but some estimate is essential in the planning of the surgical program for the patient.

When one evaluates the efficacy of surgical treatment, it is only fair to contrast it to alternative forms of therapy or no therapy at all. From the point of view of survival, the evidence appears to be clear. Untreated, survival beyond one year of the onset of symptoms or establishment of the diagnosis is rare. Radiation therapy holds some promise of palliation over and above the rigors of treatment, and appears to prolong survival beyond predicted limits. Widmann<sup>55</sup> has contrasted 167 patients with microscopically proved cases that were treated against 119 not treated. Of the latter, none lived a year. Of the 167 patients treated, 18 lived over one year, 2 for two years, 1 for three years and 1 for 5 years, and 1 was free of clinical evidence of disease six years after treatment. However, on the other side of the ledger, 89 per cent of the patients treated lived less than a year. Leddy and Moersch,<sup>86</sup> in 1940, compared 125 radiation-treated cases to a control series of 125 untreated. Clinical characterization of the two groups was remarkably similar. A salient fact of their study was that no untreated patient survived more than one year, whereas after treatment 25 patients lived one or more years, and 5 for five years or more, with 1 fourteen-year and 2 ten-year survivals in the latter group. All cases were proved histologically. Beyond improving survival time, the procedure was considered worth while on the evidence for palliation of pain and cough. Shorvon<sup>87</sup> has recently reported 111 cases treated by "radical" x-ray therapy. No patients survived beyond three years. Hocker and Guttman,<sup>88</sup> at the Memorial Hospital, discussed as a preliminary report 93 patients receiving million-volt therapy. At the time of publication in 1944, 21 patients were surviving, 4 for more than two years, and but 2 of these had no clinical evidence of disease.

### *Metastatic Tumors of the Lung*

Alexander and Haight<sup>89</sup> have recently collected 24 cases in which pulmonary resection has been carried out for presumably solitary metastatic carcinoma or sarcoma. Six of these cases were from their own clinic and the remainder were collected from the literature or by personal communication. Twelve patients had no recurrence, 8 of them sufficiently long (twelve, seven, six, five, four, three, one and a quarter and one year) after operation to justify optimism. In this series, the patients with sarcoma appeared to do better than those with carcinoma. Six of the cases were done for renal-cell carcinoma, including 1 case in which the patient has survived for thirteen years after pulmonary resection of a metastatic hypernephroma.

Effler and Blades<sup>90</sup> have recently added 3 cases, including 1 patient who, nine months after resection of a pulmonary metastasis from a sigmoid carcinoma, resected two years previously, had a cerebral metastasis removed. A recent case at the Massachusetts General Hospital demonstrates the vagaries of metastatic disease. The patient, a seventy-two-year-old man, underwent a removal of the right upper lobe for malignant melanoma metastatic to the lung. Fifteen years before, he had had an enucleation of the left eye for a similar tumor.

### TUBERCULOSIS

In his progress report for 1944, Strieder<sup>91</sup> pointed out that only recently had accepted technics been generally applied to excisional surgery for pulmonary tuberculosis. Useful as tourniquet lobectomy had been, results in the treatment of tuberculosis had been most disappointing and marred by innumerable difficulties with the bronchial stump and spread of disease during a complicated convalescence from surgery. With the proved value of individual ligation technic, the incidence of these hazards was reduced, and the question of lobectomy reopened with new enthusiasm.

By 1944, a sizable number of cases of lobectomy, with relatively few complications directly chargeable to the operative technic, had been compiled. Strieder has reviewed these at length, and pointed out the need of more time before any proper evaluation of the results can be made.

At present the long-term results of lobectomy for tuberculosis still await definition, and a new technical consideration — namely, the use of streptomycin — has entered the picture. Streptomycin therapy for tuberculosis has had extensive and critical trial in the facilities of the Veterans Administration. A report of its Streptomycin Committee<sup>92</sup> demonstrates that the practice of combining surgical procedures with streptomycin is of proved value. Beginning in March, 1947, a study

A correct appraisal of operative risks is obviously important in a decision for pneumonectomy versus lobectomy in carcinoma of the lung. Majority opinion at present favors total pneumonectomy with as extensive a lymph-node dissection as possible, to include the subcarinal nodes, the azygos node on the right and the nodes in the pulmonary ligament. If one chooses to argue by analogy to carcinoma of the breast, the position is a strong one, and certainly, other things being equal, total extirpation of a cancer-bearing organ with regional-lymph-node dissection en bloc is a major desideratum of cancer surgery. However, if one argues by analogy to gastric carcinoma, in which mortality, morbidity and disability of total versus subtotal gastrectomy are not equal, the question of lobectomy for cancer of the lung must be kept open.

Granted that it may be more informative to consider that Graham's patient, in whom a total pneumonectomy was done in 1933 for squamous-cell carcinoma of the lung, is still alive and well than to consider survival statistics at present on record, a preliminary estimate of efficacy of resection, when it is possible, may be made from the reported experience of Adams<sup>74</sup> (1948), Rienhoff<sup>72</sup> (1947), Ochsner et al.<sup>71</sup> (1947) and Graham<sup>76</sup> (1948). In so doing, one finds a total of 133 cases of pneumonectomy done five or more years prior to publication. Of these, 36 patients, or 27.1 per cent, survived five years. One of the greatest variables in the material has been the extent of the disease at the time of operation, for, as Ochsner and his associates have reported, if the disease extended beyond the lung—that is, encroachment on contiguous structures or metastasis to regional lymph nodes—only 2 of 27 patients survived three years, and none beyond six years. Yet of 15 of Graham's 53 patients who survived pneumonectomies beyond five years, 6 had positive lymph nodes at the time of operation. Coleman<sup>76</sup> has recently made the interesting observation that of 88 histologically proved cancers of the lung in his series, 6 that invaded ribs were all of squamous-cell origin (as opposed to 47 per cent of the entire series). Resection could be carried out in 5 of these patients, of whom 1 was alive and well six years and 1 two years after operation. Resection of portions of the chest wall had been carried out in 6 of Ochsner's series.

By way of contrast it would be desirable to present survival statistics for a comparable series of lobectomies done with a "curative" rather than a "palliative" objective. Unfortunately, such statistics are not presently available. In 1947 Adams<sup>77</sup> reported 5 cases of lobectomy for carcinoma with five-year survivals in 3, and Neuhof and Aufses<sup>78</sup> 24 cases with two-year survivals in 7. The latter authors have urged the importance of reporting results on the basis of the topographic features of the patient's disease, and have advocated pneumonectomy in the carcinomas of main and branch

bronchus—usually infiltrative with diffuse lymph-node involvement—and lobectomy for the circumscribed cancers without lymph-node spread and peripherally invasive carcinomas. They have stated, and this opinion was shared by few, that microscopical features were of relatively little significance after radical excision. Needless to say, survival statistics of two years in carcinoma must be accepted with caution.

Graham<sup>76</sup> has agreed that lobectomy may have a place in the treatment of carcinoma of the lung, but that if the mortality and morbidity of pneumonectomy can be kept low, the latter is the procedure of choice. As noted above, in 15 of his series of 53 pneumonectomies done prior to 1942, the patients were living and well in 1947. Head<sup>79</sup> has argued that in the older age group, pneumonectomy is a "crippling" operation, and that he has preferred lobectomy in this group when feasible. He has also warned against pneumonectomy under a mistaken diagnosis of cancer, believing that lobectomy is often indicated as a relatively safe excision biopsy when the diagnosis is in doubt. Janes<sup>80</sup> has recently reported 2 instructive cases of lipoid pneumonia simulating bronchogenic carcinoma treated surgically. Adams has suggested the following three broad indications for consideration of lobectomy: peripheral lesions of the lower lobes without grossly involved lymph nodes, upper-lobe lesions in which a clean dissection of the lobar bronchus is possible, and "palliation." Consideration of the anatomy of the tracheobronchial lymphatics<sup>81</sup> serves to emphasize the relatively small increment of lymph-bearing tissue removable by pneumonectomy over lobectomy in many lesions, particularly of the upper lobe.

Birath, Crafoord and Rudstrom<sup>82</sup> have recently discussed the quantitative measurement of pulmonary function after lobectomy and pneumonectomy. Their point of departure was the well known and previously studied<sup>83</sup> distention of the remaining lung following pneumonectomy. Total lung volume and its fractions were measured by external spirometry with a closed-circuit system, and respiratory dead space estimated by construction of a washing-out curve of nitrogen from the lungs. The latter principle has been explored extensively by Courmand and others, and has recently been elaborately refined by Bateman<sup>84</sup> at the Mayo Clinic. The material of Birath et al.<sup>82</sup> included 12 cases of pneumonectomy and 14 of lobectomy, all in adults, two to thirteen years after operation. As one might expect, after pneumonectomy the volume of the remaining lung was found to exceed by about 15 per cent the calculated normal values, the functional residual air was approximately 50 per cent higher than the predicted value for a normal lung, and the absolute residual air was even greater than 50 per cent. Thus, within the limits of the method, particularly regarding prediction of nor-

vocated routine postresection thoracoplasty in an effort to control excessive expansion of the remaining lung. In 1944, Chamberlain<sup>91</sup> stressed the factor of overdilatation as a real consideration in the choice of selective thoracoplasty over upper lobectomy. His argument was supported by bronchspirometric studies. Maier,<sup>91</sup> after similar studies challenged this position. Of Overholt's patients, only 16 per cent with upper lobectomies done as alternative to thoracoplasty had ipsilateral exacerbations if post-lobectomy thoracoplasty (second, third and fourth ribs) were done whereas the exacerbations appeared in 50 per cent who had no postoperative collapse therapy. It seems important, therefore, to demonstrate the superiority of lobectomy and thoracoplasty over thoracoplasty alone — a demonstration still forthcoming.

The heterogeneous field of extirpation for pulmonary tuberculosis has been extended to include segmental resection in a certain number of cases. The physiologic considerations of conserving lung tissue, for both its respiratory and its space-filling functions, seems to be secondary to pathologic considerations regarding the segmental nature of the disease in any given case. Reluctance to transect tuberculous tissue has been a well established principle, although streptomycin may alter this established conviction, and increasing familiarity with technics of segmental resection add some degree of safety. The fundamental nature of the disease and the objectives of surgical treatment must, however, remain the most important considerations.

#### COCCIDIOIDOMYCOSIS

Coccidioidomycosis, heretofore considered rare but disabling and often fatal, has achieved rather widespread clinical significance as a result of infection and dissemination of the disease among members of the armed forces. Its pathogenesis and pathology have been authoritatively reviewed by Forbus and Bestebreurtje.<sup>97</sup> Ninety-five cases of the disseminated form of the disease occurring in the armed forces between 1941 and 1946 are reported, 50 of these were studied clinically and at autopsy, the other 45 were confirmed by biopsy. It was apparent that coccidioidomycosis is primarily a pulmonary disease and rarely fatal except in association with endogenous reinfection. Pathologically, it is a "granulomatous" process, with many characteristics of tuberculosis, and also of many of the ordinary pyogenic infections. Primary pulmonary coccidioidomycosis is usually represented by a focal or diffuse nongranulomatous inflammatory response with regional lymphadenitis. In its severe forms, genuine suppurative and granulomatous lesions, which are sometimes destructive enough to go on to cavity formation, develop. The severe forms, which are rare, heal by scar formation and these lesions may become calcified. Secondary or disseminated disease often develops during the

active progress of the primary infection, or may spring from vegetative organisms smouldering in clinically healed but residual lesions. The authors collected 5 cases in which operation was performed when neoplasm was suspected on x-ray examination and could not be excluded. It is believed that, for approximately ten years, disseminated endogenous reinfection will continue to occur among members of the armed forces who were trained in endemic areas of the Southwest, but it does not appear likely that the disease will spread to non-endemic areas.

Greer Forsee and Mahon<sup>98</sup> have reported 15 surgically treated patients from Fitzsimons General Hospital, in whom focal pulmonary coccidioidomycotic lesions were present. These appeared as either solitary or cavitory circumscribed lesions, which closely simulated tuberculosis and from which positive pathological differentiation was possible only by recognition of the organism in tissue sections or by isolation in cultures of the lesion. Nine were treated by lobectomy, and 6 by wedge excision. In the presence of cavitation, the presence of daughter granulomas made lobectomy the preferable procedure. The indications for operation included recurrent hemoptysis, failure of the cavity to close after months of observation, spontaneous pneumothorax and inability to exclude neoplastic disease.

Churchill<sup>99</sup> has described the futility of resection in the presence of disseminated disease. In a case reported the organisms could not be recovered from the sputum in spite of a widespread consolidation of the left upper lobe, with abscess formation. The patient had obviously no biologic defense against fungous infection. A skin test with coccidioidin was negative in this case, as well as in 12 of the 28 cases so tested in the series of Forbus and Bestebreurtje.<sup>97</sup>

Studer and Morgenstern<sup>100</sup> have recently reported a case — the fourth so reported — of coexisting pulmonary coccidioidomycosis and tuberculosis.

#### SUPPURATIVE DISEASE

##### *Lung Abscess*

External drainage has gradually given way to primary lobectomy in the treatment of chronic lung abscess. Though at times life saving and occasionally the only possible surgical attack, external drainage in the past has been a relatively unsatisfactory compromise with a lethal "benign" disease. Sweet<sup>101</sup> has reviewed the experience at the Massachusetts General Hospital with lung abscess over two pre-penicillin five-year periods, 1933-1937 and 1938-1942. Each period included approximately the same number of cases (124 and 120, respectively). Comparing the two groups, he found that the curability rate rose from 49.2 to 59.2 per cent, whereas the mortality fell from 33.9 to 18.3 per cent.

was carried out in 27 hospitals in which the drug was given arbitrarily for seven days preoperatively and fourteen days postoperatively, to alternate thoracoplasty patients. Daily dosage varied between 10 and 20 gm. Streptomycin was also given to the great majority of other patients undergoing extensive surgical procedures for tuberculosis. In all, 1559 operations were performed upon 709 patients, of whom 406 received streptomycin. In the thoracoplasty group, the difference of spreads between treated (20 per cent), and untreated (56 per cent) was statistically significant, but in spite of this, the routine use of streptomycin was not advocated in thoracoplasty patients, not only because the relatively low incidence of spread in untreated cases made the practice somewhat wasteful of a rather expensive agent, but also because of toxic implications and a definite hazard of producing bacteriologic resistance. An incidence of only 4 postoperative spreads following 144 pneumonectomies and lobectomies was regarded as ample demonstration of the value of streptomycin in these procedures, in which its routine use was recommended. A total of 10 gm daily, divided into two doses and administered intramuscularly, appeared to be effective and was relatively innocuous.

The subject was accorded considerable recognition at the 1948 meeting of the American Association for Thoracic Surgery. Noteworthy was the increasing enthusiasm shown for pulmonary resection, and the reporting of rather large series of cases in which major surgical procedures could be carried out under the "benevolent mantle" of streptomycin. O'Brien et al.<sup>94</sup> rejoiced that now the maximum of definitive surgery for pulmonary tuberculosis was possible with a minimum of preliminary procedures. Active cases required a less prolonged cooling-off period than formerly before a surgical program was undertaken. In terms of operative morbidity and mortality, and also of early conversion of sputum to normal, it was apparent that immediate results were improved by use of the agent.

In 1946 Sweet<sup>91</sup> reported the total experience with pulmonary resection for tuberculosis at the Massachusetts General Hospital in the period before streptomycin was employed. The material consisted of 27 lobectomies, including the 6 reported by Churchill and Klopstock<sup>95</sup> in 1943, and 36 pneumonectomies. The surgical problems of the two groups were kept clearly distinct.

Of great interest were the 11 lobectomies that were done as alternative to thoracoplasty. The other 16 were done for the more generally acceptable indications: location of cavity unfavorable for collapse therapy, tuberculoma, atelectasis distal to stenosis, and large, rigid-walled cavity. In many of the cases adjudged suitable for lobectomy, it was striking to discover how much disease not

clearly visualized by x-ray examination existed in other portions of the lung. One, therefore, could speak with propriety of reactivation rather than of spread. Among the 27 lobectomies there were 2 postoperative deaths, 5 patients died later of their disease, 7 were alive with their disease (with positive sputum), and 13 were apparently well one to three years after operation. Among the 13 apparently well patients were 7 of the 11 patients in whom ordinarily a thoracoplasty would have been done in anticipation of a good result. Four of the 11 "alternative to thoracoplasty" patients were alive with disease at the time of the report. Of the 2 lobectomy cases that showed early reactivation of the disease, 1 was fatal, and the other cleared. Of 11 patients who suffered "late" reactivation of the disease, 4 were dead, and the remainder ill at the time of the report.

Of the 36 pneumonectomy cases, 18 were considered "desperate risks" with an excavated and almost functionless lung, and all with obviously bilateral disease on x-ray study. Of the other 18, stenosis of the main bronchus accounted for 6, and persistent cavity under properly performed thoracoplasty for 4 cases. In 5 the choice of pneumonectomy was made at operation when incomplete or absent fissures made transection of tuberculous disease almost inevitable. Seven of the patients with pneumonectomies (19.4 per cent) died in the early postoperative period, 7 died later of their disease, 5 were alive with disease, and 17 were apparently well. Among the latter were 3 of the 18 with "destroyed lungs," 5 of the 6 with "bronchostenosis," 4 of the 5 in whom the operation was done for technical reasons, and 3 of the 4 in whom thoracoplasty was a failure. The salvage of only 3 of 18 patients regarded as desperate risks, with 4 early and 6 late deaths in this group, was disappointing, and emphasized the importance of the patient's response to his disease as predetermining the success of radical surgery. In the other patients who handled their disease well biologically, radical surgery as a mechanical corrective measure appeared to be quite effective.

Overholt<sup>96</sup> has also reported his extensive pre-streptomycin experience with resection for pulmonary tuberculosis—192 cases done between 1934 and 1946—and has advocated certain technical points. Of these the face-down position has been much debated. According to its proponents, its advantages lie in less gravity drainage to the sound lung, less impairment of the chest wall and diaphragm on the sound side, less mediastinal shift, elimination of the necessity of positive pressure and the direct approach to the hilus posteriorly, with less need for hilar traction. In reply, others have advanced cogent reasons for employing the posterolateral and the anterior approach according to individual indications and preferences of both the operator and the anesthetist. Overholt has ad-

saccular disease upon which his report was based. He therefore injects a note of caution into the treatment of cases showing a maximal bronchographic extent of otherwise minimal disease.

## THE ESOPHAGUS

### Cancer

A British surgeon recently reviewed the history of esophageal resection for carcinoma, and remarked how "the bold early experiments in esophageal surgery were followed by decades spent trying to circumvent, rather than face the dangers, and recently by a return to straightforward resection with anastomosis."<sup>112</sup> In the ten years since Adams and Phemister reported the first successful intrathoracic esophagogastrostomy for carcinoma, techniques of esophageal resection in primary anastomosis have been standardized and so widely applied that a preliminary estimate of the efficacy of this, one of the latest fields of cancer, can be made. The June, 1948, issue of *Surgery* has been devoted to this subject, and contains excellent clinical characterizations of the disease, discussions of technique and editorial opinions of many of the leaders in the field. It is apparent that the majority are willing to abandon the Torek operation — credited with the first certain cure (in 1913) of carcinoma of the midesophagus — as inadequate for palliation and inefficient for cure. In support of this opinion, Sweet<sup>113</sup> has reported the total experience with the Torek procedure at the Massachusetts General Hospital. Of 14 patients 12 survived the removal of the tumor, but of these 4 died before construction of an antethoracic esophagus was begun, 4 died before the procedure was completed, 2 died after its completion, and 2 were surviving at the time of the report (four and two years, respectively).

Cancer of the esophagus differs from cancer of the lung in that its symptoms are generally so urgent that by far the great majority come to exploration, the age of the patient and his general condition notwithstanding. The distressing symptoms of slow starvation and the inability to swallow one's own saliva justify considerable operative risk and discomfort. The palliation afforded these patients if, at operation, resection and anastomosis are feasible has been deemed ample justification for the risks and surgical efforts involved, even if the prospect of cure is dim or nonexistent. Unfortunately, the anatomic relations of the esophagus make involvement of adjacent vital structures likely, though collected statistics indicate that the present resectability rate of 60 per cent of cases explored compares favorably with that of carcinomas elsewhere in the gastrointestinal tract. (To choose an example, 40 per cent of all gastric carcinomas seen at the Memorial Hospital are found to be resectable.<sup>114</sup>) Adding together the recorded experience of Sweet,<sup>113</sup> Garlock,<sup>115</sup> Strie-

der,<sup>117</sup> Clagett,<sup>118</sup> and Pack and McNeer,<sup>114</sup> which consist of total operative experience without revision by years, one finds that of 589 cases, 343 were resected, a rate of 58 per cent. Again, a compilation of the immediate operative mortality of low resection by the same group, in addition to the experience of deAmesti and Otaiza,<sup>119</sup> in Chile, and Lewis,<sup>112</sup> in Great Britain, yields 80 operative deaths in 303 cases — a rate of 26 per cent. The returns are, of course, incomplete and show considerable variation between patients, but serve as a preliminary estimate of the surgical risk involved.

Carcinomas of the midesophagus requiring a high resection and usually an anastomosis at the level of the ante-aortic or supra-aortic arch should be distinguished from those demanding a low resection. The midzonal cancers represent patients for whom, until 1944, the Torek operation was the only generally accepted procedure. In that year, Garlock<sup>120</sup> and Sweet<sup>113</sup> independently reported their experience with resection and primary intrathoracic anastomosis for these high and difficult lesions. I have been unable to find a report of Garlock's over-all experience in this regard. However, Sweet<sup>121</sup> has recently recorded his in detail, and, as the number of cases is significant and the results represent the application of a uniform technic, his report may serve to characterize the current status of surgery of the midesophagus. In contrast to a mortality of 12 per cent in 109 cases of low resection, Sweet reports 17 postoperative deaths in 72 cases of mid-thoracic esophageal resection — a rate of 23.6 per cent. Of 50 such patients reported previously, 21 had infra-aortic anastomosis, with a mortality of 19 per cent, and 29 had supra-aortic anastomosis, with 24.1 per cent mortality. The significant portion of this mortality was attributable to cardiac disorders — not surprising in view of the magnitude of the procedures and the clinical characteristics of the patients. It was believed, however, that the cardiologist's advice regarding the use of quinidine, and the limitation of salt and fluid intake, did much to reduce this type of complication.

Quite apart from the immediate results of operation and the dramatic palliation it affords, there is some reason for optimism concerning ultimate results. Sweet has analyzed his cases from the point of view of survival. His figures indicate that the majority of deaths from metastasis or recurrence of the disease occurred during the first two years after operation. Of 30 patients who had resections of the lower esophagus or cardia more than three years before the report, 23 survived operation and 9 were alive and clinically well at the time of writing (1 for seven, 2 for five, 2 for four, and 4 for three years after operation). From the point of view of survival, 82 per cent of patients who withstood the operation survived for six months, 48 per cent for a year, 44 per cent for eight months, and 31.5 per cent for two years. In most cases this

The number cured spontaneously rose slightly, from 19.3 to 23.3 per cent, and the number cured by surgery from 29.9 to 35.8 per cent. The number of lobectomies increased from 6 primary and 11 secondary lobectomies to 15 primary and 11 secondary lobectomies. In the last five years at the same hospital, it is my impression that the proportion of lobectomies, particularly primary procedures, is far higher. In the 1938-1942 group, it is of interest that of 60 drainage cases, only 19 patients could be considered cured, 9 died, 11 had secondary lobectomy, and 21 were alive with disease, which in most cases meant a troublesome fistula and a pulmonary focus of considerable potential hazard.

Glover and Clagett<sup>102</sup> have reported 37 cases of chronic lung abscess treated by pulmonary resection at the Mayo Clinic for the ten-year period, January, 1937, through December, 1946. Among 21 lobectomies there was 1 death—a bilobectomy patient who died of shock with pulmonary edema forty-eight hours postoperatively. The final result in the remaining 20 cases was an asymptomatic cure. Of the 16 pneumonectomies in which the infection had been permitted to ravage an entire lung, the results were far different. Six patients died postoperatively, and an additional 3 died of brain abscess within five months of leaving the hospital. In another 2 cases empyema developed, 1 patient requiring subsequent thoracoplasty. An additional patient had sufficient cough and dyspnea to require thoracoplasty for correction of overexpansion and mediastinal shift. Thus, in 12 of the 16 cases in which the disease had had the upper hand, either death (9 cases) or serious complications (3 cases) followed surgical treatment. These results argue strongly for a surgical attack upon the lesion when lobectomy will suffice. Unfortunately, in an urban community, many of the patients have multilobar disease when first seen by any medical adviser.

Glover and Clagett have agreed with Neuhof and associates regarding early drainage before widespread secondary changes occur, and are not prepared to decide whether in a majority, or even a significant number of these patients, bronchiectatic changes will require extirpation. They have urged resection in cases in which secondary, presumably irreversible, changes have occurred, in those anatomically unsuited to drainage, in those associated with excessive bleeding, in children, in patients in whom cancer cannot be excluded, and in cases secondary to unremovable foreign bodies.

These indications agree essentially with Lindskog's<sup>103</sup> experience. He recommends primary resection without preliminary drainage as the procedure of choice in chronic lung abscess under the following conditions: multiple abscesses or extensive destruction in one or more lobes, secondary bronchiectasis, atelectasis and pneumonitis unrelieved by bronchoscopic treatment, uncontrolled

bleeding, and perforation and localized empyema. He also reports 22 acute lung abscesses treated at the New Haven Hospital. On conservative therapy 5 patients were cured, and 3 much improved. After external drainage, 4 were cured and 4 much improved, and 1 died. Four patients required drainage of an empyema at the time of initial therapy, and 1 refused treatment.

It is probable that the place of early drainage of acute lung abscess needs redefinition if the powerful antibiotics now available can, by preventing invasive infection, reduce the amount of irreversible secondary change that converts an acute abscess into a chronic one. It is conceivable that the problem of lung abscess will resolve itself chiefly into a decision between nonoperative treatment and extirpation.

### BROCHIECTASIS

At a symposium held before the Massachusetts Medical Society in 1947 on the subject of bronchiectasis, Mallory<sup>104</sup> summarized the present theories of its pathogenesis. For each of five factors—direct bronchial infection, congenital malformation of the bronchial tree, bronchial stenosis, pulmonary atelectasis and pneumonitis—there is positive evidence of a causal relation, but none of the factors are constant or all-explanatory. He concluded that primary bronchitis and secondary atelectasis, with or without pneumonitis, could best explain the usual case, and that congenital cystic disease and bronchostenosis were relatively uncommon. The strategic point of attack, therefore, appears to be the prevention or prompt alleviation of atelectasis.

Carter and Welch<sup>105</sup> have recently presented a most interesting account of the development of bronchiectasis in 8 patients after the inhalation of a specific type of foreign body,—namely, a timothy head,—oriented stem downward. The report serves again to emphasize the respiratory hazards of childhood.

Surgical progress in bronchiectasis has been largely that of increasing safety and selectivity of operative procedures.<sup>106, 107</sup> More effective supportive measures, technical advances and extension of anatomic knowledge have contributed to the wider application of segmental resection and bilateral programs. There can be little doubt that penicillin has contributed greatly to the safety and ease of convalescence of these patients, and there is clinical evidence that aerosol penicillin may be of considerable help as a preoperative measure, particularly in patients producing copious amounts of sputum.<sup>108, 109</sup> Flooding of the airway under anesthesia has always been one of the major operative hazards.

King,<sup>110</sup> whose classic review of the subject has often been quoted to show the dismal future of bronchiectasis without surgical therapy, has recently commented<sup>111</sup> on the comparatively few patients seen nowadays that have the extensive

Unfortunately many benign strictures extend high in the esophagus, occasionally well into the cervical region. At the time of the last progress report on this subject (1944) much interest was displayed in the procedure described by Yudin<sup>129</sup> consisting of an anterior esophagus constructed from small intestine. Longmire<sup>130</sup> has recently described a modification of this maneuver by which in patients having mesenteric vessels of inadequate length, blood supply is reconstituted by direct arterial and venous anastomosis to the internal mammary vessels. Longmire<sup>131</sup> has also presented an ingenious method of enclosing a segment of jejunum in a skin tube, which is then advanced onto the chest in multiple stages, in the course of which it is freed from its mesenteric blood supply. Rienhoff<sup>132</sup> has reported a method dividing the base of the mesentery of the small bowel so as to maintain the integrity of the vascular arcades. A sufficiently long segment of jejunum is thereby obtained, and can be brought well into the chest, permitting safe esophagojejunal anastomosis at a high level. Puestow and Chess<sup>133</sup> have described 4 cases of high resection and esophagogastric anastomosis, with 1 death. They employed the technic previously described by Sweet<sup>134</sup> and used by him for high strictures of the esophagus with very satisfactory results. Harrison<sup>135</sup> has reported 2 cases of lye stricture, both in three-year-old children, in whom esophageal continuity was re-established by a three-stage procedure, in which a single loop of jejunum was brought up intrathoracically to bridge the gap between the cervical esophagus and the stomach.

Of great current interest are cases of benign stricture of the lower portion of the esophagus in which the etiology is obscure. In these cases the esophagus is frequently shortened, and there may be associated peptic ulceration. Such cases are not to be confused with idiopathic dilatation of the esophagus (cardiospasm, achalasia), whose pathogenesis reveals the confusion regarding its cause. Both the latter forms of benign lower esophageal obstruction are usually amenable to conservative measures, including instrumental dilatation. However, if these become burdensome to the patient or fail to achieve the desired functional results, a direct surgical attack is necessary.

In the idiopathic dilatation — cardiospasm-achalasia group — usually some form of pyloroplasty will suffice. Whether this is done transthoracically or transabdominally will depend on the preference of the operator.<sup>136-142</sup> The safety and versatility of the transthoracic approach has often been demonstrated, and is to be preferred when resection may be necessary.

Olsen and Harrington<sup>144</sup> have reported a series of 220 cases of esophageal hiatus hernia of the short-esophagus type. Eighty-nine of these had significant ulcerations of the esophagogastric junction,

which could be controlled in the majority of cases by conservative therapy, including instrumental dilatation if obstruction was present. Abdominal operation in this group was unsatisfactory. The authors have discussed the etiology of peptic ulceration of the lower esophagus and drawn freely from the literature on the subject. Several interesting hypotheses are advanced to explain the short esophagus. They agree with Allison's<sup>145</sup> suggestion that peptic ulceration of the lower end of the esophagus may be the cause. The peptic ulceration may result from excessive or prolonged vomiting, or from constant bathing of the lower end of the esophagus in acid secretion, owing to incompetence of the physiologic sphincter of the cardia in association with hiatus hernia. The authors also refer to experimental evidence of Dev et al.,<sup>146</sup> who demonstrated reflex shortening of the esophagus on direct or indirect vagal stimulation. The latter might be translated to their 18 patients who had an associated duodenal ulcer, and 39 others with long histories of "dyspepsia."

Clark and Adams<sup>147</sup> have discussed transthoracic esophagogastronomy in 5 cases of benign obstruction of the lower end of the esophagus after failure of conservative therapy. One of these patients had esophagitis associated with scleroderma, in 3 the etiology was obscure. No ulceration was described. Allison<sup>145</sup> has urged operative attack when conservative measures fail. When the peptic ulceration is accompanied by inefficiency of the diaphragm, which allows the stomach and abdominal esophagus to slide up into the mediastinum — a "landslide" type of hernia — he suggests that the length of the esophagus be restored, the stomach replaced in the abdomen, and the size of the hiatus corrected. When chronic ulceration and fibrosis make reduction of the anatomic deformity impossible, excision of this segment may be necessary.

Sweet<sup>145</sup> has reported 51 cases of repair of hiatus hernia by a transthoracic approach, which he favors because of the greater exposure obtained, the versatility of access and the freedom from complications. In the 51 cases described, intractable pain was the indication for operation in 68 per cent, incarceration in 18 per cent, and acute or chronic blood loss in 14 per cent. Soutter<sup>148</sup> has reviewed all the cases of surgical repair of hiatus hernia done at the Massachusetts General Hospital over the years and has concluded that the incidence of recurrence is lower and symptomatic relief greater after transthoracic rather than subdiaphragmatic repair.

In the course of a comprehensive review of the subject of diaphragmatic hernia, Harrington<sup>150</sup> has discussed the many aspects of the problem and has reviewed his experience with 404 cases treated surgically. Two hundred and eighty-seven of these were esophageal hiatus hernias, for which he preferred an abdominal approach to the defect, usually preceded by a temporary phrenic paralysis.

meant prolongation of life with relative comfort, for recurrence in the anastomotic site was uncommon. With this in mind it is difficult to agree with the following statement of Nielsen<sup>122</sup>

To us there is no doubt that the difficult task of trying to treat esophagus cancer both radically and symptomatologically will, to a very great extent, continue to be the domain of radiotherapy. All imaginable advances of thoracic surgery notwithstanding, only a small percentage of carcinomas in the esophagus will be amenable to surgical treatment, and the number of these in which a complete cure will be obtained will be smaller, still.

Nielsen has described an ingenious method of therapy, which delivers an effective amount of radiation to the tumor by rotating the patient vertically in the radiation field. Since the esophagus is an axial structure, the effective tumor dose is delivered with a minimum amount of radiation to any one area at the periphery. Of a total of 194 cases of carcinoma seen, only 8 were considered unsuitable for x-ray therapy. Of the 174 patients treated by rotation therapy, 140 received satisfactory tumor dosage. Of those treated by rotation therapy, 25 per cent were alive in one year, and 15 per cent in two years. If one corrects Sweet's survival statistics to total number of cases resected and not merely those surviving operation and therefore having the opportunity to survive, 42 per cent were alive at one year, and 34 per cent survived for two years. The point is well taken, however, that in the nonresectable cases x-ray therapy may have palliative value. It is fair to state that the experience of others with x-ray therapy for carcinoma of the esophagus has not been so encouraging as that of Nielsen. Thus, Holmes and Schulz,<sup>123</sup> using supervoltage radiotherapy, found that only 8 per cent of patients survived for one year, and 2 per cent for two years.

Cancer of the cervical esophagus has stubbornly maintained the upper hand over surgical attack, although occasional successes in this region have been reported. Watson and Pool<sup>124</sup> have reviewed the historical aspect of the problem and made note of a twenty-three-year survival following surgical resection of a lesion of the cervical esophagus, reported by Evans in 1934, and a ten-year cure reported by Trotter in 1937. The authors themselves reported 2 cases ten years after combined surgical and x-ray therapy, and 1 case clinically free of disease seven years after surgical excision. Reviewing 77 cases of surgical esophageal cancer admitted to the Memorial Hospital from 1940 to 1947, they found that 22 per cent had clinically positive lymph nodes on admission. Survival after x-ray therapy averaged fifteen months in cases in which treatment failed to arrest the disease, but 3 patients treated more than fifteen months before the time of report were alive and well at that date. Of 7 patients treated by resection, 1 died within three months of operation, and the remainder were alive four, six, nine, twelve, thirty-

six and eighty-four months, respectively. Using a similar operative approach Sweet<sup>115</sup> has reported 7 cases with excellent immediate results, but in each case, within six months to a year after operation, local recurrence or evidence of cervical-lymph-node metastasis became apparent. With 1 exception, all patients were dead at the time of his report.

The technic of cervical esophagectomy has been described in detail by Wookey,<sup>125, 126</sup> of Toronto. The procedure is designed to re-establish esophageal continuity at a second stage, and in many cases the larynx can be preserved. The operation, which is historically related to procedures described by Trotter and Eggers, consists of a block excision of the involved cervical esophagus.

Cancers in this area are almost invariably epidermoid, and the Memorial group,<sup>114</sup> at least, have believed that etiologically they bear a definite relation to chronic irritation in the oral cavity and to leukoplakia. As in other cancers, one of the major difficulties has been delay in diagnosis, occasioned chiefly by the surprising vagueness and lateness of symptoms of cancer in this region,—a scrappy throat, halitosis and ill defined discomfort on swallowing,—many of the ills often being ascribed to excessive smoking, postnasal drip or bad teeth. Pack<sup>127</sup> has decried the ritualistic aura surrounding the esophagoscope that has prevented its early and widespread use.

Perhaps the most difficult of all zones to resect, and fortunately the one least commonly involved in carcinoma, is the upper fourth of the thoracic esophagus. Cancer at the thoracic inlet is difficult of access, for both removal and reconstruction. Sweet<sup>115</sup> has reported a successful case in which, after removal of such a growth, an intracervical esophagogastrostomy was performed, the fundus of the stomach having been brought up through a defect in the upper thorax formed by resection of the inner end of the clavicle and first rib. Bricker and Burford<sup>128</sup> have recently described a pedicle tube flap for reconstruction of the upper esophagus following resection, with radical neck dissection and anterior thoracotomy.

### *Benign Obstructions*

It is not surprising that heroic measures refined to a point of safety in the treatment of malignant lesions of the esophagus should be extended to include certain benign but often distressing conditions. Thus, although bougienage may be adequate for cicatricial obstruction resulting from chemical burn, in a variable number of patients it will be distasteful to the point of intolerability and occasionally impossible or extremely hazardous. Under these circumstances, resection and direct esophago-gastric anastomosis seems logical, especially in the group of younger persons whose cardiopulmonary systems are sufficiently resilient.

the graft had taken well to the diaphragm and pleura

Asthma continues to be a relatively undiscovered country for the thoracic surgeon. In 1948, Carr and Chandler<sup>65</sup> reported 5 patients in whom encouraging clinical results followed post-ganglionic resection of the upper dorsal sympathetic ganglions. In discussion of their report, Abbott pointed out that head his associates approached the problem by an attack on the parasympathetic system. Similar conflicting clinical evidence was added by Adams. The problem awaits definition of the pathologic changes and disturbances of physiology under attack, and the relation of the lung to the autonomic nervous system.

In conclusion, a final word might be added — namely, the obvious importance of ruling out cancer in cases considered to be benign obstruction. To this end, the combination of careful x-ray study and esophagoscopy examination is necessary, and often must be repeated before cancer can be ruled out beyond reasonable doubt.

### *Congenital Atresia*

At the other end of the time scale from resection of the esophagus for carcinoma is an equally formidable operative procedure for the correction of esophageal atresia and tracheoesophageal fistula. Haight,<sup>161</sup> who is credited with the first successful direct anastomosis of the esophagus in 1941 (there were several near misses just prior to that time, notably Shaw's case in 1939), has recently reported 52 cases in which an effort was made to restore esophageal continuity. In 11 of the 52 patients an esophageal anastomosis was not possible, and in another patient it was not done. In 1 of these cases an esophagogastric anastomosis was done by Dr F X Byron. Of 40 patients for whom an esophageal anastomosis was completed, 22 died, and 18 recovered — a recovery rate of 45 per cent. The over-all recovery rate in the 52 patients explored was 34.6 per cent. Haight and his associates favor a right extrapleural exposure of the anomaly, particularly if the preoperative x-ray film demonstrates air in the stomach — a sign that there should be a sufficient length of the two segments to permit anastomosis. When air is not present in the stomach before operation, agenesis of the lower esophagus is commonly found and direct end-to-end anastomosis of the esophagus is impossible. Haight<sup>16</sup> had previously emphasized the great difficulty in securing a suture line without tension since swallowing and crying, after the effects of the anesthesia have worn off, tend to raise the upper portion of the esophagus, and the descent of the diaphragm on inspiration exerts traction downward.

Ladd and Swenson<sup>153, 154</sup> have reported experience with this disease at the Children's Hospital and suggested a new classification of the anomaly to supersede that of Vogt. Thirty-nine primary anastomoses were carried out, with 20 recoveries. Forty-three multiple-stage procedures produced 16 living patients, of whom 5 subsequently had an antethoracic esophagus completed. Their experience with a transpleural approach was disheartening: 4 deaths out of 5 attempts. Swenson<sup>154</sup> has recommended a two-layer, watertight interrupted-fine-silk anastomosis, and reports only one fistula in 15 patients, and this closed spontaneously.

In the occasional case in which, for anatomic reasons, direct anastomosis is not possible, a multiple-stage procedure may be considered, aiming first at the closure of the tracheoesophageal fistula, cervical esophagostomy, ligation of the lower esophageal segment, some form of gastrostomy, and

finally reconstruction of an anterior esophagus. As Lam<sup>155</sup> has demonstrated, the last may require great persistence in the face of many discouragements. Sweet<sup>156</sup> has attacked the problem successfully in 2 children who had esophagostomy and gastrostomy early in infancy as a life-saving measure. He subsequently performed a successful intracervical esophagogastrostomy after advancing the stomach through the chest, posterior to the hilus and out through a new thoracic inlet formed by resection of the inner end of the clavicle and first rib.

Pulmonary complications have been a limiting factor in the surgical correction of this major developmental anomaly. For this reason, the use of small amounts of lipiodol are much to be preferred over barium at the time of x-ray examination. Furthermore, because of the danger of spilling over into the tracheobronchial tree, operative intervention should not be postponed beyond the minimum time necessary to attend to the physiologic needs of the infant.

### MISCELLANEOUS CONSIDERATIONS

Surgery of the heart and great vessels qualifies for a progress report in its own right and will not be considered here. However, a rather closely related entity, variously called pulmonary arteriovenous aneurysm,<sup>157</sup> pulmonary cavernous hemangioma,<sup>158</sup> hemangioma of the lung<sup>159</sup> and arteriovenous fistula of the lung,<sup>160</sup> has been the subject of many recent reports. As the names imply, this lesion furnishes a vascular shunt across the pulmonary circuit so that deficient oxygenation of the systemic arterial blood results. On the basis of this deficiency, with its clinical manifestations of cyanosis, clubbing and polycythemia, in addition to the finding of a lung tumor that emits a bruit, the diagnosis can be made. Dramatic improvement has followed lobectomy in the cases reported.

Mediastinal tumors continue to be a source of never-ending speculation. Maier<sup>161</sup> has reviewed the problem of bronchogenic cysts of the mediastinum and recorded 8 additional cases. Within the past year, Byron, Alling and Samson<sup>162</sup> have each had a case of intrathoracic meningocele that presented as a smooth outlined and lobulated posterior mediastinal mass. Review of their cases, as well as the 5 previously recorded in the literature, showed that the lesion is frequently associated with widening of the intervertebral foramina, erosion of the rib and vertebra and even diffuse neurofibromatosis. Since excision of the meningocele is usually deemed inadvisable or impossible, they have suggested the use of a contrast medium intraspinally in the x-ray differential diagnosis.

Watson and James<sup>163</sup> and Maier<sup>164</sup> have described the management of large defects of the chest wall. The former have suggested a large fascia-lata graft, and in 1 patient, who died of pulmonary embolism eighteen days after such a repair, they found that

A barium enema, gastrointestinal series and films of the spine were reported normal. X-ray films of the chest showed cardiac enlargement, a possible dilatation of the ascending aorta and wide aortic pulsations. The serum nonprotein nitrogen was 23 mg and the sugar 106 mg per 100 cc. The prothrombin time was 18 seconds (normal, 17 seconds). The amylase was 32 units per 100 cc and the serum albumin 4.6 gm, and the globulin 3.7 gm per 100 cc, giving an albumin-globulin ratio of 1.26. The urine culture was negative. A lumbar puncture was not remarkable, the Wassermann reaction was negative, and the spinal-fluid protein was 38 mg per 100 cc. An electrocardiogram was not diagnostic.

The patient had several severe attacks of left-upper-quadrant pain while on the ward without definite relation to food intake or defecation. During one such typical episode he was found sitting in bed hunched over a bed table. Deep palpation of the abdomen revealed acute tenderness just to the left of the umbilicus, and there was a sense of resistance to palpation without detection of a definite mass in the area. Neither nitroglycerin nor sodium bicarbonate gave any relief. He was discharged to be followed in the Out-Patient Department.

**Final admission** (two weeks later). The patient returned to the hospital by ambulance, having been bed ridden at home. He appeared dehydrated and emaciated and gave a history of continued, severe, nonradiating, left-upper-quadrant pain since discharge. On two or three occasions he had vomited, with temporary relief of pain. In addition he appeared weaker.

Physical examination was the same as on the previous admission, except the liver was felt to descend three fingerbreadths on deep inspiration. An intravenous pyelogram and a left retrograde pyelogram were negative. Sigmoidoscopy to 16 cm was normal. The stool was guaiac positive on four of seven occasions. The urine concentrated to 1.027 and gave a + test for albumin and there were 20 white cells, 5 red cells and occasional casts per high-power field in the sediment. The hemoglobin was 10.5 gm. The white-cell count was 8000, with 20 per cent myelocytes and myeloblasts. A hematologic consultant found myeloid hyperplasia on the smear and sternal biopsy. The serum lipase was 1.2 mg, and the nonprotein nitrogen 38 mg per 100 cc. The van den Bergh reaction was negative, the cephalin flocculation test was negative. The calcium was 9.6 mg, and the phosphorus 4.6 mg per 100 cc and the alkaline phosphatase 6.6 Bodansky units.

The patient was prepared for exploration by 12 gm of sulfasuxidine and 2 gm of sulfadiazine daily (as urinary antiseptic), transfusion and Miller-Abbott intubation. The white-cell count rose to 13,400 on the thirteenth hospital day, when

a urine culture was positive for colon bacilli and *Staphylococcus aureus*. On the seventeenth hospital day he was drowsy, and an emergency non-protein nitrogen was 116 mg per 100 cc. The operation was cancelled, and the Miller-Abbott tube withdrawn. He continued to be lethargic and apathetic, and at 1:30 a.m. of the eighteenth day he went into sudden collapse and died.

#### DIFFERENTIAL DIAGNOSIS

**DR. RICHARD B. CATTELL\*** This man's past history evidently had little to do with the present findings and complaints. There are two things that we can begin with in this case: he was in the cancer age, at sixty-two, and this is supposed to be a conference for the New England Cancer Society. I think Dr. Cabot always said that if one is frequently out on a limb the percentage diagnosis is the one to take. We will assume it is cancer.

In the past history it is stated that he had a diverticulum of the cecum. This is exceedingly rare. Dr. Castleman will tell you how many cases they have in their files.

**DR. BENJAMIN CASTLEMAN** I do not believe I have ever seen one.

**DR. CATTELL** That bears out my impression. This man had syphilis, syphilitic heart disease, aortic regurgitation and hypertensive heart disease and probably, as indicated by the x-ray film, dilatation of the aorta. He did not have a palpable mass at any time. He could localize the symptoms in the left upper quadrant, and there are certainly lesions that occur in this region. The findings in the gastrointestinal tract were all negative except for guaiac-positive stools on the second examination, which should exclude involvement of the stomach or colon, although a positive guaiac reaction can occur without an actual ulcerative lesion. On this admission there was a new blood finding—myeloblasts were found in the sternal marrow. This was a terminal blood condition and was not, in my opinion, myeloblastic leukemia, although that is a definite possibility.

I think from all we have pointed out here in the way of symptoms that we have a lesion in the retroperitoneal area, probably not involving the pancreas or if it did involve the body or tail of the pancreas it extended to involve other organs as it became progressive. With carcinoma of the body of the pancreas "in the silent area" where few symptoms are produced, the commonest symptom in our experience is pain in the back, not in the left upper quadrant but in the back, that usually passes over to involve the other side. The second group of symptoms is entirely missing in this history, and that is the usual presence of bowel symptoms, which are characteristic of any pancreatic lesion that involves and obstructs the duct of Wirsung. We have had 165 carcinomas of the pancreas since

### CASE 34511\*

#### PRESENTATION OF CASE

*First admission* A sixty-two-year-old Negro janitor entered the hospital complaining of left-upper-quadrant pain of three weeks' duration.

Five months previously the patient developed a nonradiating, dull pain in the left upper quadrant, which responded quickly to the bland diet on which he was placed. Recurring three weeks before admission this pain became increasingly severe and was especially bad after the evening meal and during the night. He had no other digestive complaints except mild constipation. There

was a 20-pound weight loss during these three weeks.

Nineteen years before admission he had had an excision of the cecum and appendix, with side-to-side ileocolostomy for diverticulitis of the cecum. Eight years before admission he received a one-year course of intramuscular injections following the detection of a positive serologic test at another hospital. He had been aware of high blood pressure and a heart murmur for two years, without specific cardiovascular symptoms. He had an increase of nocturia from one to four or five times during the month before entry.

Physical examination showed a tall, thin man who had water-hammer pulses, a blood pressure of 210 systolic, 50 diastolic, and a heart enlarged to the sixth interspace in the anterior axillary line. The aortic second sound was increased over the pulmonic second sound. Grade III aortic diastolic and Grade I apical systolic murmurs were heard. The abdominal aorta was prominent. No masses were felt.

Examination of the blood revealed a white-cell count of 7400, with 80 per cent neutrophils. The hemoglobin was 13 gm. A blood Hinton test was negative. The urine concentrated to 1028 and gave a + test for albumin, and there was a rare red blood cell, white blood cell and cellular cast per high-power field. The stool was guaiac negative.

\*Presented at a meeting of the New England Cancer Society held at the Massachusetts General Hospital.

region. There was also a metastasis within the liver and one to the serosa of the stomach. On microscopical section the cells tended to be quite spindle shaped and in some places were composed of dense collagen. The appearance was most consistent with a fibrosarcoma, probably of neurogenic origin, that had involved both sides of the abdomen. The cells in many places were very atypical with numerous mitoses, and it seems to me that he could not have had a tumor as wild as this for a long time. The fact that the tumor occurred on both sides would be in favor of some form of neurogenic tumor perhaps arising from neurofibromas. There were no metastases to the lung. Pressure on the ureters perhaps accounted for some degree of the pyelonephritis and probably was the cause of the elevated nonprotein nitrogen toward the end. An incidental finding was the presence in the second and third lumbar vertebrae of grayish-white tissue, not at all connected with the tumor in the retroperitoneal space, that the prosector thought was another metastasis but, on microscopical examination, proved to be a chordoma. It was just picked up on routine sectioning of the vertebral column. I do not believe it produced any symptoms. I wonder if Dr. Robbins can possibly see it in these x-ray films.

DR. LAURENCE L. ROBBINS: Certainly the density of the lumbar vertebrae is increased, but I do not remember a chordoma doing that.

DR. CASTLEMAN: It was very soft.

DR. ROBBINS: I would not be able to make a definite diagnosis of the lesion.

DR. CATTELL: You cannot see anything in the right or left adrenal gland?

DR. ROBBINS: No.

## CASE 34512

### PRESENTATION OF CASE

*First admission.* A thirteen-year-old girl was admitted to the hospital complaining of a dry, persistent cough.

At the onset of the dry cough three years before admission nasal polyps were found. The cough continued following polypectomy. Several months later her tonsils and adenoids were removed, as were recurrent nasal polyps, without improving the chronic cough. Ten weeks before admission the cough became severe and was accompanied by large amounts of greenish-yellow, foul-smelling sputum. Vomiting followed severe paroxysms of coughing. She complained of headache and abdominal pain. She lost 13 pounds during this period. Five days before admission the temperature was 102°F.

The patient was the fifth of five children. Two older siblings, twenty-six and seventeen years old, were well. One sibling had died at the age

of eight months from pneumonia which had been present for a long time. Another had died at the age of eight weeks of vomiting, which had been present since birth.

The patient had been born at term following an uneventful pregnancy. The birth weight was 9 $\frac{3}{4}$  pounds. Development during the first ten years of life was similar to that of her siblings except that she was slightly obese. Since infancy she had been a voracious eater, and the stools were always large and bulky. She had had measles, chicken pox, mumps and German measles, and in each case apparently recovered without aftereffects. She had annual winter colds with cough from early childhood on, which tended to last all winter and were more severe than the other siblings' colds.

Physical examination showed a poorly developed and undernourished girl, with wasting of the buttocks and extremities. The right anterior chest was prominent, and the fingers and toes were clubbed. The chest was emphysematous and hyperresonant, with diffuse, dry rales throughout. The abdomen was round, protuberant and tympanic with active peristalsis. The liver and spleen were questionably enlarged. A white, glistening mass obstructed the right nares. The weight was 26.7 kg, and the height, 153 cm.

The temperature was 101°F, the pulse 110, and the respirations 20. The blood pressure was 90 systolic, 60 diastolic.

The urine was normal, the stools were light, foul smelling and fatty. The fat percentage of dry weight was 21.4. The stool nitrogen was 5.2 gm in twenty-four hours. The white-cell count was 23,600, with 68 per cent neutrophils, 28 per cent lymphocytes and 4 per cent monocytes. The hemoglobin was 12.2 gm. The reticulocyte count was 0.8 per cent. The fasting blood sugar was 67 mg per 100 cc. The total protein was 6.9 gm per 100 cc. The prothrombin time was normal, the cephalin flocculation test was +++ in twenty-four and forty-eight hours. The bromsulfalein test was normal. The vitamin A tolerance test showed a fasting level of 0.1 units per cubic centimeter (carotenoids) and 0.1 units per cubic centimeter (vitamin A). Five hours after a test dose of oil-soluble vitamin A the levels were 0.1 and 0.6 units per cubic centimeter. The calcium was 8.3 mg per 100 cc, and the phosphorus 3.6 and the alkaline phosphatase 8.6 units.

X-ray study of the chest demonstrated increased lateral and anteroposterior chest diameters and a low diaphragm (Fig 1). Throughout both lungs there was irregular, strand-like, parenchymal density (Fig 2). Clouding of all the nasal sinuses was found. The bones of the lumbar spine, pelvis, hands and wrists showed moderate generalized decalcification. The bone age was not retarded. Throat cultures demonstrated a varied flora on consecutive examination. Friedländer's bacillus,

August, 1942 They usually begin with bowel symptoms caused by decreased pancreatic enzymes available in the bowel No bowel symptoms were present in this patient, but this is possible with carcinoma of the body and tail, particularly if a portion of the pancreas remains available to furnish the external pancreatic enzymes through the duct of Wirsung into the duodenum I do not believe we have an ulcerative lesion that involves or invades the gastrointestinal tract, although one can see this with a lesion in this location, with involvement of the first portion of the jejunum as well as the more common lesions of the pancreas that ulcerate into the second portion of the duodenum There are some things inconsistent with pancreatic primary neoplasm There is no evidence that this was one of the tumors arising in the islands of Langerhans There was no change in metabolism of glucose About 30 per cent of these were carcinoma in our experience at the time the patients were operated on So we would consider this to be a primary lesion arising in the tail or body of the pancreas, with gradual extension The pain of carcinoma of the pancreatic body may be relieved by leaning forward and is characteristically found Whoever saw this patient and took this history was impressed with that one clinical fact

The other diagnosis we have to consider is kidney neoplasm This can reasonably be excluded Would you like to show the x-ray films?

DR CASTLEMAN The only x-ray films available are those taken between the first and second admissions and these are all normal

DR CATTELL A definitely ulcerated lesion in the region of the ampulla of Vater may occasionally be demonstrated by roentgenographic means In carcinoma of the body of the pancreas one may see displacement of the stomach upward, and sometimes can see evidence of displacement of the ligament of Treitz If this is a large retroperitoneal tumor, the commonest ones are neurofibroma, fibrosarcoma, leiomyosarcoma and lipomyosarcoma We ought to be able to feel a mass and see displacement of the kidney, stomach, small bowel or colon I do not believe this is a retroperitoneal tumor because of the rapid progression to death

DR RALPH E MILLER What do you think this blood picture was due to?

DR CATTELL I know very little about hematologic findings I would think it was a terminal state in a failing patient due to marked stimulation of the marrow I do not believe he had a myelogenous leukemia

DR MILLER Do you think it consistent with extreme metastases to the liver from a carcinoma?

DR CATTELL I do not believe so from the findings, although it might well be

DR GRANTLEY W TAYLOR Did you consider an aortic aneurysm in the differential diagnosis? He had a background of syphilis

DR CATTELL As I read the report I considered it seriously but threw it out on the basis of my first remarks

A PHYSICIAN How about the barium enema? Was that negative?

DR CASTLEMAN It was reported as negative.

A PHYSICIAN On the first admission?

DR CASTLEMAN Yes

DR KNOWLES B LAWRENCE I would suggest carcinoma of the splenic flexure with complications

DR CATTELL That is a definite possibility, but the barium enema was negative

DR THOMAS J ANGLE For how many days was sulfadiazine given?

DR CASTLEMAN For six days during the last admission

DR JOSEPH ROSS Is there any implication of the report of myeloid hyperplasia at the biopsy?

DR CASTLEMAN I think it meant hyperplasia of the myeloid elements but no myeloma

DR CATTELL That was my interpretation

DR CASTLEMAN Just a shift to the left

#### CLINICAL DIAGNOSIS

Carcinoma of pancreas

#### DR CATTELL'S DIAGNOSIS

Carcinoma of body of pancreas

#### ANATOMICAL DIAGNOSES

*Retroperitoneal fibrosarcoma, bilateral, with involvement of both adrenal glands and with metastases to liver and stomach*

*Chordoma of lumbar vertebrae*

#### PATHOLOGICAL DISCUSSION

DR CASTLEMAN The clinical impression was the same as Dr Cattell's that the patient had carcinoma of the pancreas One opinion reads as follows

This sixty-two-year-old man with syphilitic heart disease has left-upper-quadrant pain of about two months' duration, associated with weight loss and occasional vomiting. All x-ray examinations have failed to disclose the site of the lesion in the abdomen, so the tail of the pancreas has been considered as the site of a neoplasm The history of constipation of two years' duration, worse in recent months, suggests a colonic lesion (carcinoma of the splenic flexure), but the barium enema was negative I agree that laparotomy is now indicated and will not be surprised to find a retroperitoneal tumor in the left upper quadrant, with possibly a lymphoma, or no intra-abdominal disease

At autopsy the patient had a retroperitoneal tumor, a very malignant tumor, and its distribution was rather unusual It involved both sides of the abdomen The larger mass was located in the region of the right adrenal gland, completely obliterating it, and extending into the liver on that side as well as invading into a portion of the terminal ileum There was a similar but smaller tumor on the left side involving a portion of the left adrenal gland and extending into the tissues around that

increase in the anteroposterior diameter of the chest. There is no detectable enlargement of the heart, and no fluid is present in the costophrenic sinuses.

Examination of the chest made five months after admission shows a slight increase in the pulmonary involvement particularly in the apical segments.

The final examination of the chest made nine months after the first admission discloses a definite progression of the pulmonary changes. The focal areas of increased density are more marked. There is more emphysema, as shown by further flattening of the diaphragm. An additional finding at this time is a slight prominence of the right ventricle as seen on the lateral film.

The films of the paranasal sinuses are of considerable interest. They show almost complete obstruction of the nasal fossa by a polypoid soft-tissue mass. Marked thickening of the mucous membrane, with polypoid change, is seen in the maxillary, ethmoid and sphenoid sinuses. The frontal sinuses remain clear.

DR ROSS: Do you think there is alveolar involvement in the final film?

DR MCCORT: There are irregular patches of density in the peripheral lung. We cannot be certain whether they are atelectatic lobules or cellular infiltration of the alveoli.

DR ROSS: In arriving at this inevitable diagnosis we get help from the family history of one infant with chronic pulmonary disease, lasting eight months and ending in death, presumably, the same disease. An eight-week-old infant dying after persistent vomiting suggests, again without proof, that one child died of meconium ileus, a condition that has been described in association with cystic fibrosis of the pancreas in the newborn period. We know that the condition is commonly a familial, congenital disease. The persistent symptoms from early childhood—the voracious appetite, with rapid growth and apparent obesity—mean, I think, that this child met the requirement for growth by eating tremendous quantities, more than the average person, although a good deal was not absorbed as evidenced by the bulky, foul stools. The final occurrence of severe, persistent respiratory disease fills out the picture. The laboratory data of low serum calcium, the osteoporosis and the low vitamin A and carotenoids all indicate poor fat absorption. The absent tryptic enzyme activity shows that there was no pancreatic juice passing into the duodenum. The enlargement

of the liver, with the suggestively positive cephalin flocculation test, also suggests the possibility of some cirrhotic changes in the liver, which have been described in pancreatic fibrosis. However, the final enlargement of the liver on the last admission suggests more to me right-sided heart failure due to prolonged pulmonary emphysema.

Pancreatic fibrosis in a thirteen-year-old child is unusual. Most of the cases previously presented in these gatherings have been in young infants or in children just above the age of infancy. There have been cases reported sporadically in the literature of older children—none older than fourteen and a half years. The striking situation here is the late onset of the alarming symptoms—the alarming symptoms being due not to nutritional deficiency but to infection of the respiratory tract.

The best that could be done with chemotherapy was to control the infection. The underlying disease of the mucous membranes indicated by polyps and progressive emphysema, with probable fibrosis in the lungs, was not controlled—the use of various chemotherapeutic agents caused the change from one pathogen to another, without finally being able to keep ahead of the disease. My diagnosis is, therefore, pancreatic fibrosis. Dr Reversbach may have some comments about our present experience with this disease.

DR GERTRUD C. REYERSBACH: We have followed a number of children with this disease. The oldest we have is twelve and a half years old, having had diarrhea since birth and respiratory symptoms for five years. The next is ten years old and has had bulky stools since birth, respiratory symptoms starting at four years. Both these children have been treated with penicillin, streptomycin, and one also with a diet and pancreatin. We wonder whether we have helped these children to survive by therapy. When we go back to the literature we find quite a number of cases exactly the same as this in which the patients survived without therapy. Thus, the question whether our therapy helps is doubtful.

Our experience with treating the respiratory infection, which seems to be the lethal factor, has been disappointing. We are able to treat the *Staph aureus*, the causative agent of the infection, generally found at first and quite successfully for a time. Then the staphylococcus is replaced by gram-negative organisms: *B. pyocyaneus*, colon bacillus and so forth. We add streptomycin in the

*Staphylococcus aureus* and beta-hemolytic streptococcus. Two duodenal aspirations showed no tryptic enzyme activity.

The temperature and cough subsided on sulfadiazine and aerosol penicillin. The appetite was good. She was discharged after one month of hospitalization.

**Second admission** (four months later). During the first month after discharge sulfadiazine was continued at home, and the patient felt well. Fol-

lowing its discontinuance her condition was stabilized for a few weeks, but gradually recurrent cough, fever, weight loss and large, foul, frothy stools, averaging three or four each day, appeared. The physical signs were similar to those on the previous admission. On aerosol penicillin and streptomycin the symptoms subsided, and she was discharged one month after admission.

**Third admission** (three months later). Complaints and findings were similar to those on the second admission. There was some improvement on aerosol penicillin. She was discharged two weeks after admission.

FIGURE 1

**Final admission** (one month later). For a few days preceding admission she became febrile, chilly, cyanotic, dyspneic and orthopneic, and she had paroxysms of productive cough. On examination she was cyanotic. There was a small area of dullness and diminished breath sounds in the right base. The chest was otherwise hyperresonant. The liver edge was palpable two fingerbreadths below the costal margin. The temperature was

#### DIFFERENTIAL DIAGNOSIS

**DR RALPH A. ROSS:** This story has all the stark, grim inevitability of a Greek tragedy. The patient had a family history of two siblings who died in infancy, one of chronic infection and the other of neonatal intestinal obstruction. The patient herself had a history of a large appetite throughout life, even in the midst of acute illness, bulky stools, with severe respiratory infection from childhood.

FIGURE 2

and with cough and nasal polyps since ten years of age. Physical examination disclosed malnutrition, a protuberant abdomen and emphysema, with clubbing, in addition to x-ray findings, which were apparently those of general pulmonary involvement leading to a sum total of what we call cystic fibrosis of the pancreas.

May we see the x-ray films?

**DR JAMES J. McCORT:** An examination of the chest made on admission shows a patchy and mottled increase in density throughout both lung fields. Within this there are numerous radiolucent areas. The diaphragm is flat, and there is an

usual picture of cystic fibrosis of the pancreas seen in infancy. Whether it is possible for the latter to develop to the stage of complete disappearance of acinar tissue I have not the experience to say. Dr Sidney Farber informs me that he does believe it is possible.

The lungs showed the characteristic picture that we see in cystic fibrosis. They were very large; the entire bronchial tree was filled with rather inspissated purulent secretion. There was emphysema beyond the obstructed bronchi and the infection had extended here and there into the alveolar lumens, but the great majority was still in the bronchi.

The organ that interested me most was the liver. This was greatly enlarged, weighing 2000 gm, which would be large for the liver of an adult and was extremely large for this child. It was very fatty (Fig 4) as one would expect to find the liver of an animal that had a total pancreatectomy and had been kept alive with insulin — the type that Chaikoff<sup>1</sup> and Best<sup>2</sup> and various others have described. There was cirrhosis but not a portal cirrhosis, which develops from the lack of pancreatic secretions but a very clear-cut, biliary cirrhosis. All the small bile ducts were filled with plugs of inspissated material tinged with bile although not consisting primarily of bile pigment (Fig 5). I feel quite sure that the actual cirrhotic process was due to plugging of the bile ducts and was biliary in type. The fat infiltration, in contrast, might be traced to deficiency of pancreatic external secretion and had nothing to do with the development of the cirrhosis.

DR BUTLER: In Best's experimental animals he got fatty livers first, and then the cirrhosis seemed to come and replace the fatty liver, so that at one stage there was fatty liver and at a later stage cirrhosis.

DR ROSS: Has this been seen in infants?

DR REYERSBACH: Yes, it has. It is of interest because the clinical pictures vary so much in infants and in children in the same family — three siblings with the same disease — one dies at six months,

the next one at six years, and the next at ten, twelve or fourteen years. Going through the autopsy reports and the literature, I happened to find that the condition described today has been found at least four times in infants as well as in children aged four or more.<sup>3</sup> Whether that is different from the usual fibrosis of the pancreas I do not know.

DR MALLORY: In the case reported by Siwe<sup>4</sup> the pancreatic lesion was apparently entirely similar to that in this case — complete replacement of

FIGURE 5

acinar cells with adipose tissue and persistence of the islands of Langerhans. He interpreted it as agenesis of the acinar tissue. His case also showed cirrhosis of the liver but as far as I can judge from his illustrations and description it was portal rather than biliary in type.

course of the disease. Often, all the organisms become drug resistant. We may have given this child help in combating the infection and may have prolonged life, but we have not made any definite changes.

DR. TRACY B. MALLORY: The experience is almost exactly similar to that of treating bronchiec-

tasis with chemotherapeutic agents. One can change the bacterial flora very readily. One gets rid of the staphylococcus only to have it replaced with the colon bacillus. Whether the agents serve any useful purpose is very doubtful.

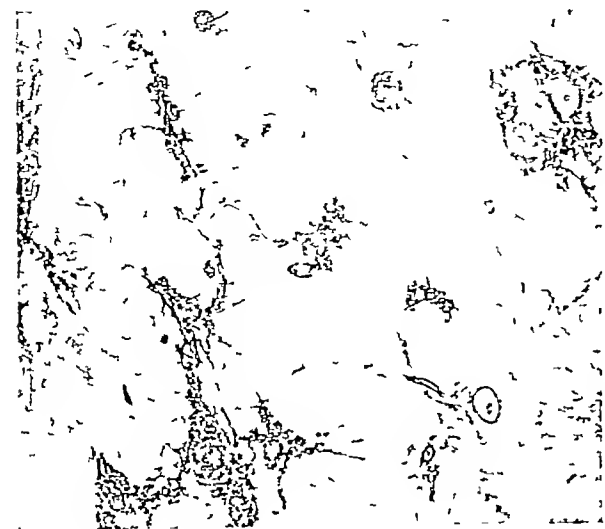

FIGURE 3

tasis with chemotherapeutic agents. One can change the bacterial flora very readily. One gets rid of the staphylococcus only to have it replaced with the colon bacillus. Whether the agents serve any useful purpose is very doubtful.

DR. ALLAN M. BUTLER: Your mention of bronchiectasis brings up the connection between a patient such as this and the group of cases Dr. Churchill's service has been interested in, characterized by nasal polyps, underdevelopment of the sinuses, chronic sinusitis, bronchiectasis and status inversus. What is the difference in the bronchiectasis of this group, who have no pancreatic fibrosis, as far as I know, and of patients with pancreatic fibrosis?

I do not know whether you found cirrhosis of the liver at post-mortem examination of this patient, but our findings on the ward made it suspect. It reminds one of the experience of Dr. Best with depancreatized dogs developing cirrhosis of the liver. Such cirrhosis could be prevented by the administration of choline or methionine. It is odd that in many patients who have no external secretions of the pancreas so little cirrhosis of the

DR. MALLORY: We found very severe pancreatic disease, but there were no cysts and not a great

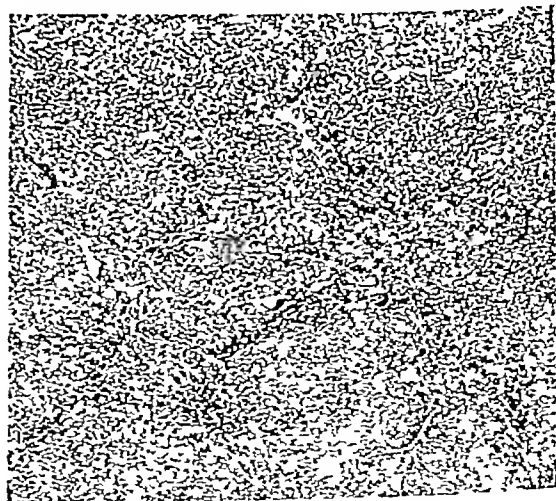

FIGURE 4

deal of fibrosis. There was a small, fibrous area close to the head of the pancreas in about the spot where the pancreatic duct should have been, but we were entirely unable to identify the pancreatic duct. The remainder of the pancreas consisted of fatty tissue (Fig. 3) and islands of Langerhans that looked normal. There were no acinar cells left, so that the microscopical appearance was essentially what one sees following ligation of the main pancreatic duct and did not resemble the

usual picture of cystic fibrosis of the pancreas seen in infancy. Whether it is possible for the latter to develop to the stage of complete disappearance of acinar tissue, I have not the experience to say. Dr Sidney Farber informs me that he does believe it is possible.

The lungs showed the characteristic picture that we see in cystic fibrosis. They were very large, the entire bronchial tree was filled with rather inspissated, purulent secretion. There was emphysema beyond the obstructed bronchi and the infection had extended here and there into the alveolar lumens, but the great majority was still in the bronchi.

## ONE WORLD

THE relations of human beings, one with another, too often represent the very extremes of human conduct. Bitterness and hate and cruelty as expressed by individuals and nations and races is thrown into sharp contrast with those great emotional surges of tenderness and compassion that at other times may animate almost all men and seem at all times to animate some of them.

The consciences and the emotions of the common people of a nation tend in the main to direct their thoughts and activities into the channels of compassion. Thus the people of this country, coldly as they may sometimes have been viewed by their fellow citizens of a world drawn closer together by mutual interdependence and swift travel, still pride

themselves on their generosity and their feeling of good will toward the common people of all other nations.

Aside from the vast gifts that national policy has dictated should be put into the hands of the Wise Men for distribution to our stricken neighbors, there has been a constant flow of more spontaneous, if lesser, offerings of good will to all those who suffer and who could be reached.

The air bridge to Berlin has carried more than food for the mouths and coal for the bins of our recent enemies and present wards, it has carried good will in a franker form to the children of that city under siege as a spontaneous expression of kindness and generosity on the part of American airmen.

Santa Claus in numerous guises and directing a variety of carriers, working in all seasons and without vacation, has delivered a continuous stream of freely offered gifts from these shores to all available quarters of the globe. And yet these earnestness of good intention on the part of a people conscious of its own favorable situation represent but one manifestation of a general good feeling that needs only the opportunity to prevail. Various religious and sociologic organizations have this year held meetings on an international plane, not the least among them being the World Council of Churches, the World Health Organization and the World Medical Association. The United Nations stand ready to hang a Christmas wreath on the door of nearly every country in the world and even, with some trepidation, to pin one upon the Iron Curtain itself.

The United States, at long last, has officially admitted and sincerely welcomed a new band of pilgrims to set foot upon her shores—at the Thanksgiving season, with fitting symbolism. May their Christmas in a new land be a happy one, and may this land fulfill the promises of freedom and opportunity that it has so far seemed to these displaced persons to offer!

Each year at this time it is well to remember that good will is communicable, that if enough people wish it "Earth shall be fair and all her people one", that through their will they may yet see peace on earth.

## MASSACHUSETTS PHYSICIANS COMMITTEE

ON NOVEMBER 22, 1948, a group of physicians from various parts of the Commonwealth met and voted to form a Massachusetts Physicians Committee for the purpose of promoting free enterprise and the preservation of a system of private practice in medicine in this country. This committee was formed not to oppose, but to assist, not to hinder but to help, not to destroy but to build up. Believing in the same health goal, if not in the methods of reaching it, that Mr Ewing has established in his report to the President — namely, the extension of the best possible medical services to all the people of the country, — it offers its assistance in helping to achieve those ends by the best possible means.

It believes that this goal can be most nearly approximated by preserving the system of private medical practice with all the reforms and safeguards for the people that experience may suggest, by the promotion and extension of voluntary prepayment plans, and by assisting government at the most effective level in furnishing the same adequate service to those who cannot afford to bear their share of the costs.

This committee is fearful of the waste and extravagance and inefficiency that may accompany an attempt at reaching the common goal by means of any system of compulsory, tax-supported or political medicine. It is fearful of the distance that such a system, however innocuous it appears at the beginning, may eventually travel.

It does not believe, as the chairman of the Committee for the Nation's Health believes, "that national health insurance does not mean regimentation of doctors or state control, and will not interfere in any way with the doctor-patient relationship." It does agree with him that "The time has come to take the politics out of health," but it does not agree that the passage of a bill for government-controlled national health insurance will achieve that end.

Working in harmony with the organized profession of medicine and with all other healthy inter-

ests, it invites the help of the physicians of the Commonwealth in studying these matters of general concern, in enlightening the public and in lending all the aid possible to the Government and the people in establishing the health care of the nation on a secure basis.

## UNDERGRADUATE INSTRUCTION IN ALLERGY

A COMPREHENSIVE survey has clearly demonstrated that satisfactory instruction in allergy is not being provided in the majority of the leading medical schools today. New England institutions, unhappily, prove no exception to the rule. This conclusion is based upon the results of a questionnaire<sup>1</sup> returned by sixty-six schools, less than half of which were found to have an acceptable minimal curriculum in allergy.

Should such an observation call forth the comment "why bother our students about sneezes, wheezes and itches," the answer seems clear. Few can deny that many young internists have completed their medical training with little or no contact with allergy or allergic thought.<sup>2</sup> Some medical and much lay opinion still classes allergy as a narrow specialty whose chief qualification is the ability to perform and the inability to interpret skin tests. On the contrary, altered reaction in general is the province of the allergist. Such a heading embraces the principles of sensitivity, of anaphylaxis, of immunology. It includes altered reactivity to proteins, bacteria, nonbacterial substances and drugs. Allergy is concerned with the practical management and pathogenesis of many diseases. It is closely interrelated with the fields of bacteriology, biochemistry, pathology, metabolism, circulatory disorders and psychosomatic medicine — in short, it is part and parcel of internal medicine.

No allergist can fulfill his maximum responsibility to his patients and to his specialty unless he has a background of sound medical training. In like manner, no internist should be regarded as well trained in internal medicine unless he is thoroughly

cognizant of the principles of anaphylaxis and allergy and of their application to medicine. It is high time that departments of medicine recognized the need of adequate undergraduate training in allergy. They should then take steps to obtain suitable facilities and to organize them in such a manner as to provide systematic and enlightened training.

### GUIDE TO HEALTH SERVICES

A USEFUL key to the health services available in the Greater Boston area has been prepared by the Boston Health League and sent to all physicians practicing in the area. Arranged according to type of specialized service, the information it offers runs the scale from adoption and care of the aged to well-baby conferences, workmen's compensation and x-ray services.

The complexity of the facilities available in a great metropolitan area make such a handbook nearly indispensable. With the *Handbook for Physicians* published by the Massachusetts Department of Public Health, and the *Directory of Social Service Resources of Greater Boston*, emanating from the Greater Boston Community Council, it completes an invaluable triad of such guides.

### OBITUARY

#### ABRAHAM MYERSON (1881-1948)

The death of Dr Abraham Myerson on September 3, 1948, in his sixty-seventh year ended a distinguished medical service of more than thirty-five years in this community.

Dr Myerson graduated from Tufts College Medical School in 1908. After a period of practice in Boston he trained for a career in neuropsychiatry by serving as resident neurologist to Alexian Brothers Hospital in St. Louis, 1912-1913, and assistant physician to the Boston Psychopathic Hospital, 1913-1914. From 1914 to 1918 he was pathologist and clinical director of the Taunton State Hospital, from 1918 to 1920 he served as chief medical officer of the outpatient department of the Boston Psychopathic Hospital. Thus he acquired a background

and experience in neurology, neuropathology and intramural and extramural psychiatry. His teaching experiences began in St. Louis and were continued in Boston. He became professor of neurology at Tufts College Medical School and taught this subject in an inspiring manner to generations of medical students. He was clinical professor of psychiatry at Harvard Medical School. Throughout his life his interests encompassed both neurology and psychiatry. He was visiting neurologist to the Boston City Hospital, neuropsychiatrist to the Beth Israel Hospital and consultant in neurology or psychiatry to several other institutions.

Dr Myerson became interested in research early in his medical career, and for more than thirty-five years he made outstanding contributions to medical literature. Two of his early interests were syphilis of the nervous system and genetics, and to the end he continued to investigate and report on these subjects. The scope of his research interests widened greatly, encompassing the effects of social, environmental and internal stresses on the one hand and metabolic and biochemical changes concomitant to mental illness on the other. The first group of studies are found in books from his pen, namely, *The Nervous Housewife*, *Foundations of Personality* and *When Life Loses Its Zest*. Many papers appearing in the medical literature document other types of work. In recognition of his abilities and accomplishments a research building was erected at the Boston State Hospital, and, aided by a large grant from The Rockefeller Foundation, he became director of research of an active organization.

He was a member of many medical societies, served on many committees and was elected president of several. He published eight books and more than a hundred and fifty scientific papers.

These cold facts give no adequate picture of Abraham Myerson. His dynamic personality, his speaking ability, his quick wit and humor, his logical thinking, his friendliness and his devotion to social improvement, civic affairs and human rights are more to the point. He was a stimulating teacher, guide and friend to students. He was a leader of many younger colleagues in their research efforts. He was a most popular lecturer to lay groups and was ever ready to interpret psychiatry to the laity as well as to his medical colleagues.

He was strong in his opinions and fearless in his expression of them. Book reviews by Myerson were forthright, explicit and critical. Praise was not withheld when considered merited, but statements inimical to his point of view were brilliantly and vigorously attacked. He was a strong and articulate opponent of psychoanalysis. To do justice to the subject and express his opinion, he read everything written by Freud as well as a vast amount of other psychoanalytic literature, becoming

ing almost encyclopedic in his knowledge of literature on this subject

With great dynamic qualities of personality, with deep erudition and learning, with brilliance, wit and articulateness, with strong emotional devotion to good causes and with a great store of energy he was indeed a force in the medical world — local, national and international. Perhaps no better testimony of his influence is needed than the fact that his two sons follow his footsteps in neuropsychiatry and his daughter is training in psychiatric social work.

A final word about his strength of character and great spirit is due. For seven years he was aware that he had a progressive cardiac ailment. Never for an instant did he seek sympathy, never did his broad interest in science and literature diminish. Until his last hours he continued his intellectual efforts and only wondered how much he could accomplish in the brief interval before death would stop him.

## MASSACHUSETTS MEDICAL SOCIETY

### DEATHS

**BARTON** — Robert B. Barton, M.D., of Wellesley Hills, died on November 30. He was in his forty-eighth year. Dr. Barton received his degree from Boston University School of Medicine in 1926. He was a fellow of the American Medical Association.

His widow and two daughters survive.

**PAINE** — N. Emmons Paine, M.D., of Walpole, died on November 30. He was in his ninety-sixth year.

Dr. Paine received his degree from Albany Medical College in 1875. He was the founder of the Newton Sanatorium and was formerly superintendent of the Westboro State Hospital and a member of the staffs of Newton-Wellesley Hospital and Massachusetts Memorial Hospitals. He was professor emeritus of psychiatry at Boston University School of Medicine and was a fellow of the American College of Physicians and the American Psychiatric Association.

A son and two daughters survive.

**SCHWAGER** — Solomon Schwager, M.D., of Pittsfield, died on November 30. He was in his fifty-eighth year.

Dr. Schwager received his degree from New York University College of Medicine in 1917. He was a fellow of the American Medical Association.

His widow and two sons survive.

## CORRESPONDENCE

### DOCTOR DRAFT

To the Editor: The editorial entitled "Concerning the Doctor Draft," which appeared in the November 11 issue of the *Journal*, contains the following statements:

Congress's contemplated action will concern chiefly doctors who were trained under ASTP and V-12 at Government expense but were unable to complete their term of active duty. If they should be required to complete their contract in a few months of peace-time service, it would seem too reasonable a sacrifice to be fairly resented.

There are a few errors here.

In the first place, we completed our term of active duty as determined by the Army and Navy.

Secondly, we have no contract broken or otherwise with the Government. With the exception of those who volunteered for the inactive reserve, we all have certificates of honorable discharge — no strings attached.

Finally, most of my colleagues who are former ASTP S or V-12's do not resent being drafted if it is necessary. We do resent slander and lies concerning us, especially in the press.

Are you brave enough to print this in toto?

KENNETH BRUNS  
Senior Medical Student  
Formerly AS V-12 USNR

493½ Forest Park  
St. Louis, Missouri

NOTE: In a literal sense Mr. Bruns is exactly right, although careful examination fails to reveal any hint of disparagement or slander in the wording of the editorial. Certainly none was intended. "Contract" was broadly used in the sense of implied obligation to repay the Government's investment by a period of active duty. ASTP S and V-12's who have served the originally intended term of active duty are morally quits with the Government that paid their tuition; those who have not (through no fault of their own, as specified in the editorial) have certainly broken no contract. However, many of them, and apparently Mr. Bruns among them, are still conscious enough of an obligation to be willing to discharge it in full when and if the necessity arises. In this they show themselves to be patriotic, responsible and fair-minded citizens, differing in no way from the overwhelming majority of the medical profession. — Ed

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Headache and Other Head Pain*. By Harold G. Wolff, M.D., professor of medicine (neurology) and associate professor of psychiatry, Cornell University Medical College and attending physician, New York Hospital, New York. 8°, cloth, 642 pp., with 154 illustrations. New York: Oxford University Press, 1948. \$12.00 (Oxford Medical Publications.)

The author in this comprehensive book summarizes his studies of fifteen years on the subject of head pain, including migraine in all its aspects and relations. Selected bibliographies are appended to the various chapters. The publishing is well done. The book is recommended for all medical libraries and should prove valuable to all neurologists and other physicians interested in the subject.

*Voluntary Medical Care Insurance in the United States*. By Franz Goldmann, M.D. 8°, cloth, 228 pp. New York: Columbia University Press, 1948. \$3.50.

This book, a companion to *Public Medical Care*, describes and analyzes the development and present state of voluntary medical care insurance and appraises the most important types of organizations in the United States including profit, nonprofit and group plans. The volume is well published and should be in all medical public and insurance libraries.

## MORAL PROBLEMS IN THE PRACTICE OF MEDICINE\*

With Analogies Drawn from the Profession of the Ministry

WILLARD L. SPERRY, M A, D D, S T D, AND LITT D T

CAMBRIDGE, MASSACHUSETTS

MAY I begin what I have to say to you this afternoon by thanking Dr Means for his kind invitation to me to share your staff meeting with you. And may I add my thanks to all of you for your co-operation in the Institute of Pastoral Care, which heads up at the Massachusetts General Hospital.

The fact that I am here at all and that this institute is centered at your hospital is symptomatic of one of the most significant facts in our life today — the fact that, as in the natural sciences, so in the sciences of man and in the professions, the party walls between fields of specialization are not so high as they once were. When I began my ministry I kept bachelor's hall with a well known surgeon. Occasionally I went his rounds with him. One night he routed me out to go along with him to a hospital. He was giving oxygen to a dying patient. As we came out of the room he said, "She'll be gone before morning." I asked, "What happens to her then?" He replied, "That is your business, not mine. You and I are never in the sick room at the same time. We meet at the doorway. You come in as I go out." That would hardly be said today. Our professions may not coincide, but they do overlap.

May I continue by saying that the standards of your profession are, on the whole, higher than those of any of the other professions. I saw this without disparagement of the earnestness and the devotion of the members of my own profession. But the separation of church and state in America forbids the state to do anything whatsoever to maintain decent minimal standards for the ministry, whereas the Commonwealth can and does require of you an adequate education before you may practice medicine. Not only so, but your own professional ethics, over and above the competence required by law, maintain your usage at a very high level. Take a single instance. A professional man is not supposed to advertise. If the newspapers carried, day by day, medical parallels to the ad-

vertisements run by the churches on a Saturday and the publicity that ministers allow themselves on Monday, any doctor who sanctioned such self-advertisement would find himself charged at once with unprofessional conduct. I do not hesitate, in dealing with students in the Divinity School, to call attention to the high ethical standards that prevail in the field of medicine.

I have been asked by Dr Means to talk about certain problems that we share together — problems that are more properly moral rather than medical. We shall come to cases a little later on. But I have to warn you, as I warned him in accepting his invitation, that these problems have no single, simple solution. However, Havelock Ellis once said that the important thing is not to find a man who knows the answer to your problem, but to find a man who knows what the problem is. Were I minded to do so I could cite problems in the practice of my own profession that are, in principle, substantially those which Dr Means had in mind in inviting me here. I merely ask you to take it for granted that I am not wholly unfamiliar with the type of situation that you face.

When we talk about morals and ethics we may mean one of two things. The two words mean, linguistically, the same thing — the *mores* or the *ethos* of a society, that is, the mean high-water mark of accepted manners in a given society. Thus a recent *Handbook of Psychiatry* (Overholser and Richmond) says, "Conscience is not something that is born in the individual, but something that is acquired from the practices, the beliefs, the attitudes and the customs of the group with which the individual identifies himself. For the average individual his conscience is the crystallized attitude of his group." This is a purely naturalistic sociologic account of morals. It makes large room for relativity in the whole field of ethics, and for the changes in moral standards of which all of us are aware.

On the other hand there are persons, and these in the main professedly religious persons, who are not content to define and dismiss morality as a

\*Presented at a staff meeting of the Massachusetts General Hospital, Boston, January 19, 1948.

†Dean, Harvard Divinity School.

## GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in Building E, Harvard Medical School, on Tuesday, December 21, at 8 15 p.m. A symposium on virus diseases will be presented, with Dr. John F. Enders as chairman.

## PROGRAM

- The Diagnosis of Virus Diseases of the Respiratory Tract  
Dr. Maxwell Finland
- The Prevention and Treatment of Virus Diseases of the Respiratory Tract  
Dr. Monroe D. Eaton
- Recent Advances in the Diagnosis and Treatment of Certain Rickettsial Diseases  
Dr. John C. Snyder
- The Interpretation of Reactions Following Smallpox Vaccination  
Major Abram S. Benenson, M.D.

## AMERICAN ASSOCIATION OF SCHOOLS OF SOCIAL WORK

The American Association of Schools of Social Work will hold its thirtieth annual meeting at the Hotel Statler, Boston, on January 27, 28 and 29, 1949.

## MAINE MARITIME ACADEMY

A position of medical officer is available for the annual cruise of the Maine Maritime Academy, which begins on January 8 and continues until April 4, 1949. A straight fee of \$1000, in addition to maintenance for the three months' cruise, is usually paid.

Further information regarding qualifications may be obtained from the Superintendent, Maine Maritime Academy, Castine, Maine.

## NATIONAL FOUNDATION FOR INFANTILE PARALYSIS FELLOWSHIPS

The National Foundation for Infantile Paralysis announces that the following fellowships are available to qualified applicants: research fellowships in virology, orthopedic surgery, pediatrics, epidemiology and neurology (available to doctors of medicine, or, when appropriate, doctors of philosophy, the former having a minimum of two years of training on the residency level, of sound health, as attested by a physical examination, citizens of the United States who can present an appropriate program of study and investigation), clinical fellowships in physical medicine for physicians who wish to prepare for eligibility for certification by the American Board of Physical Medicine (available to graduates of Class A medical schools who have completed a rotating internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, licensed to practice medicine in one or more states, citizens of the United States, forty years of age or younger and of sound health, as attested by a physical examination), and fellowships in public health for postgraduate study leading to the degree of Master of Public Health at a school of public health approved by the American Public Health Association (available to graduates of Class A medical schools who have completed not less than one year of internship in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, licensed to practice medicine in one or more states, citizens of the United States and of sound health as attested by a physical examination).

For further information regarding the fellowships, application should be made to the National Foundation for Infantile Paralysis, 120 Broadway, New York 5, New York. Selection will be made on a competitive basis by committees composed of specialists in each field, and awards will be based on the individual needs of the applicants.

## AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, INC.

The next written examination and review of case histories (Part I) for all candidates will be held in various cities of the United States and Canada on Friday, February 4, 1949.

Arrangements will be made so far as possible for candidates to take the Part I examination (written paper and submission of case records) at places convenient for them.

Candidates who successfully complete the Part I examination proceed automatically to the Part II examination to be held May 8 to 14 inclusive, 1949, at the Hotel Shoreland, Chicago, Illinois. Notice of the exact time and place of the Part I and Part II examinations will be sent all candidates well in advance of the examination date.

New bulletins are now available for distribution upon application and give details of all changes in Board requirements and regulations made at the annual meeting of the Board held in Washington, D. C., May 16 to May 22, 1948. These apply both to candidates and to hospitals conducting residency services for training.

Application forms and bulletins will be sent upon request made to the American Board of Obstetrics and Gynecology, Inc., 1015 Highland Building, Pittsburgh 6, Pennsylvania.

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, DECEMBER 23

## FRIDAY, DECEMBER 24

- \*9 00-10 00 a.m. Craniopharyngioma. Ophthalmic Type due to Pituitary Tumors (Demonstration and Discussion of Cases Operated on by Transphenoidal Methods) Dr. Oscar Hirsch. Joseph H. Pratt. Diagnostic Hospital.
- \*9 00 a.m.-12 00 p.m. Combined Medical and Surgical Staff Rounds. Peter Bent Brigham Hospital.

## MONDAY, DECEMBER 27

- \*12 15-1 15 p.m. Clinicopathological Conference. Main Amphitheater. Peter Bent Brigham Hospital.

## MORAL PROBLEMS IN THE PRACTICE OF MEDICINE\*

With Analogies Drawn from the Profession of the Ministry

WILLARD L. SPERRY, M.A., D.D., S.T.D., AND LITT.D.†

CAMBRIDGE, MASSACHUSETTS

MAY I begin what I have to say to you this afternoon by thanking Dr. Means for his kind invitation to me to share your staff meeting with you. And may I add my thanks to all of you for your co-operation in the Institute of Pastoral Care, which heads up at the Massachusetts General Hospital.

The fact that I am here at all and that this institute is centered at your hospital is symptomatic of one of the most significant facts in our life today — the fact that, as in the natural sciences, so in the sciences of man and in the professions, the party walls between fields of specialization are not so high as they once were. When I began my ministry I kept bachelor's hall with a well known surgeon. Occasionally I went his rounds with him. One night he routed me out to go along with him to a hospital. He was giving oxygen to a dying patient. As we came out of the room he said, "She'll be gone before morning." I asked, "What happens to her then?" He replied, "That is your business, not mine. You and I are never in the sick room at the same time. We meet at the doorway. You come in as I go out." That would hardly be said today. Our professions may not coincide, but they do overlap.

May I continue by saying that the standards of your profession are, on the whole, higher than those of any of the other professions. I say this without disparagement of the earnestness and the devotion of the members of my own profession. But the separation of church and state in America forbids the state to do anything whatsoever to maintain decent minimal standards for the ministry, whereas the Commonwealth can and does require of you an adequate education before you may practice medicine. Not only so, but your own professional ethics, over and above the competence required by law, maintain your usage at a very high level. Take a single instance. A professional man is not supposed to advertise. If the newspapers carried, day by day, medical parallels to the ad-

vertisements run by the churches on a Saturday and the publicity that ministers allow themselves on Monday, any doctor who sanctioned such self-advertisement would find himself charged at once with unprofessional conduct. I do not hesitate, in dealing with students in the Divinity School, to call attention to the high ethical standards that prevail in the field of medicine.

I have been asked by Dr. Means to talk about certain problems that we share together — problems that are more properly moral rather than medical. We shall come to cases a little later on. But I have to warn you, as I warned him in accepting his invitation, that these problems have no single, simple solution. However, Havelock Ellis once said that the important thing is not to find a man who knows the answer to your problem, but to find a man who knows what the problem is. Were I minded to do so I could cite problems in the practice of my own profession that are in principle, substantially those which Dr. Means had in mind in inviting me here. I merely ask you to take it for granted that I am not wholly unfamiliar with the type of situation that you face.

When we talk about morals and ethics we may mean one of two things. The two words mean, linguistically, the same thing — the *mores* or the *ethos* of a society, that is, the mean high-water mark of accepted manners in a given society. Thus a recent *Handbook of Psychiatry* (Overholser and Richmond) says, "Conscience is not something that is born in the individual, but something that is acquired from the practices, the beliefs, the attitudes and the customs of the group with which the individual identifies himself. For the average individual his conscience is the crystallized attitude of his group." This is a purely naturalistic, sociologic account of morals. It makes large room for relativity in the whole field of ethics, and for the changes in moral standards of which all of us are aware.

On the other hand there are persons, and these in the main professedly religious persons, who are not content to define and dismiss morality as a

\*Presented at a staff meeting of the Massachusetts General Hospital, Boston, January 19, 1948.

†Dean, Harvard Divinity School.

matter of social custom. Such persons feel that the distinction between right and wrong, in whatever terms these two words may be defined, has about it a certain absolute quality. Thomas Carlyle says that the greatest moment in modern European history was that when a lonely man stood before a hostile court and said, "It is dangerous to sin against conscience." Most of us have had moments in which we were aware of that danger. In the ancient Wisdom Literature of Israel there is a verse in which God says, "Thou hast not as it were forsaken me, thou hast forsaken thyself." To "forsake oneself" is a serious business, the process may eventually become suicidal for character.

Therefore, I commend to you another account of morals by Father George Tyrrell.

The rock of irresistible reality is conscience — the sense of right and its absolute claims. No analysis, no explaining away can permanently destroy this faith or lay the ghost. Only conscience can say, "Thou shalt have no other gods before me, thou shalt not bow down to them or worship them, for I the Lord thy God am a jealous God."

The sciences of man can prove beyond all contradiction the relativity of moral judgments at any given place and time. A practice that yesterday was declared to be permissible, if not right, is today declared to be forbidden and wrong. Polygamy and human slavery are two historic instances of this proposition. The prodigal varieties of moral judgment, and the fact, which each one of us has verified in his own experience, that conscience is educable, inclines the sociologist to regard the whole matter as one of ethical relativity. But the religious man cannot abandon altogether his conviction that, whatever its particular pronouncement at any given moment, the principle of conscience has an absolute warrant. No rationalization can explain, much less explain away, this conviction, which has its origins in the belief that the life of man is lived in touch with an "Infinite Mystery" and that our attempts to distinguish between right and wrong have their ultimate origins in the nature of "The Eternal Goodness." The process of ethical culture still goes on, but the quality of an ethical conviction remains constant.

To come more closely to our immediate subject, the actual moral choices that we have to make in this world are seldom between black and white, they are between shades of gray. One of my friends, who taught the undergraduate classes in ethics at Yale, used to say that once we have chosen the lighter shade of gray, we must then, for all practical purposes, go ahead on the assumption that it becomes for us a clear white.

The narrator in Conrad's *Lord Jim* says of his tragic hero that, given his dilemma, there was only a hairbreadth, only the thickness of a sheet of paper, between right and wrong. Once again all of us have had experience of this narrow margin between our moral options.

The most serious and by far the most difficult moral decisions we have to make are those that involve two rival loyalties, each of which is wholly good on its own premises, but which cannot be easily squared. I cited you a moment ago Father George Tyrrell. There is in his autobiography a poignant passage that harks back to just such a collision of loyalties in his own early life. He had felt a call to the religious life and had decided to join a religious order. But his decision meant abandoning to their own fate a needy mother and sister who, humanly speaking, had simple prior claims upon him. Looking back on his decision he said years later:

Well I remember my last day at home, my last day with those two now hid in death's dateless night, who were my share of the world, the best this life has had for me — whom I forsook for what? in the name of all that is sane and reasonable? For a craze, an idea, a fanaticism? Or for the love of and zeal for the truth, the Kingdom of God, the good of mankind. Had I been faithful to my duty all along, had I stayed at home and supported my mother and sister and made their sad narrow lives a little wider and brighter, would not God have given me light needful for my salvation? Have I done so much good to others who had no claim on me to atone for my neglect of those who had every claim? What have I given up or forsaken for the service of God, as I suppose some would call it, except my plain duty? These are the pleasant doubts that fill my mind in the spare moments, and make me say, Surely I have lived in vain.

In his *Oxford Lectures on Poetry*, A. C. Bradley has an essay on "Hegel's Theory of Tragedy." He points out that tragedy is never a matter of a conflict between good and evil. Such a conflict is forthright and never tragic. The essence of tragedy is, as we have said, a matter of a collision of two loyalties, each of which is wholly good on its own ground.

The essentially tragic fact is the self-division and intestinal warfare of the ethical substance, not so much the war of good with evil as the war of good with good. The family claims what the state refuses, love requires what honor forbids. The competing forces are both in themselves rightful, and so far the claim of each is equally justified, but the right of each is pushed into a wrong because it ignores the right of the other.

Professor Bradley illustrates this thesis at great length from the great Greek tragedies and from those of Shakespeare. Clytemnestra has killed her husband and her king. Orestes, her son, is ordered by Apollo to avenge his father, but to kill one's mother is itself a sin against filial piety. The bond of father and son demands that which the bond of son and mother forbids. Richard Lovelace, on going to the wars, says to his *Lucasta*:

Yet this inconstancy is such  
As you shall too adore  
I could not love thee, dear, so much,  
Loved I not honour more.

This was Othello's tragedy: his passionate love of Desdemona and his duty to his honor were at the final fatal moment incompatible, so he "put out the light."

The essence of tragedy, then, is not pain or suffering. The essence of tragedy is waste. We are confronted again and again with what William James has called "a forced, momentous option." This option cannot be avoided, a choice must be made, but when it is made something good in itself is inevitably lost.

In this analysis of our moral problems we come here to an area of life where crude rules of thumb, which serve the humdrum needs of every day, are of little help. We must go to art, and perhaps to religion, to understand the nature of our dilemma and to find there some element of resignation and reconciliation.

To come to still closer grips with our problem let me take two or three instances of the tragic dilemma with which we are only too familiar. At these points the professions of medicine and the ministry constantly overlap. Please understand that what I may say hereafter provides no dogmatic resolution of the tragic dilemma. I offer merely my own reflections upon situations that are even more familiar to you than they are to me, and yet situations that, over the years, I have shared with you. For there are times when a patient asks a priest or minister or rabbi questions that he shrinks from asking his doctor.

#### TELLING THE PATIENT THE TRUTH

This issue was, you remember, one that was vigorously debated here in these very circles some years ago, when a gallantly and remorselessly sincere man urged truth telling at all costs.

One might dodge the issue by asking in turn, with Pilate of old, "What is truth?" Bacon said that Pilate was merely a jester, who would not stay for an answer. My observation is that many wise physicians and surgeons are cautious about claiming finality for their diagnoses and prognoses. In the order of nature there are run-of-the-mill diseases that, humanly speaking, must apparently go their normal course to the end. It is a matter of common knowledge that the faith-healing sects in this country have made much of their capital out of hasty and erroneous diagnoses. Some would-be truth teller, who misinterpreted the facts, has dismissed them, perhaps to the ministry of devout believers, but certainly to the *vis medicatrix naturae*. This, however, is more immediately your problem than mine. Furthermore, as one of you said to me not long ago we never know when some new treatment and possible cure may come suddenly around a corner. Years ago a little daughter of Dean Inge of St. Paul's and a son of L. P. Jacks were taken to London hospitals in the last stages of diabetes, to await the first insulin that was being flown to England from Canada. The girl, alas, died, the lad lived to get his insulin and still lives happily.

But when there is reasonable assurance as to diagnosis and prognosis, what are the doctor, and the minister who shares the doctor's opinion, to do?

Much, perhaps all, depends on a patient's temperament and mental state at the time. Resolute natures, in full possession of their wits usually want to know what we think and expect, and are able to "take it." I see no reason or warrant for withholding what we believe to be the truth from such a person. I mentioned that Yale professor a few moments ago. He had an obscure illness and died untimely, after going the rounds of specialists in both New York and Boston. He was a man of quick intellect and good courage. He once said to me in a mood of discouragement and temporary bitterness, "I no longer believe anything that any doctor says to me. They have all lied to me so consistently that I have lost all faith in them." This was a bit of deliberate overstatement on his part, but I think he meant that he was tired of being cheered up by a too facile optimism, or dismissed with deliberate perplexity.

On the other hand many persons do not even ask themselves how ill they are, let alone asking any one else. They prefer to take what comes, as it comes. The reticence of such persons should be respected. There is no occasion and no moral obligation to intrude the supposed truth upon such minds. To do so would be a bit of gratuitous cruelty. And all of us know that there is a point in the course of an illness at which nature herself mercifully dulls the mind and its power of grasping ideas begins to relax. In his Ingersoll Lecture on the Immortality of Man, given at Harvard some years ago, William Osler said that most people die as they were born, unconscious of what is happening. You doctors know this well. I have to tell my divinity students that this is so, and that at these times they are not to ask or expect anything like quick mental response to their ministry to the sick. These are not the occasions to carry on a prolonged discussion as to an afterlife.

In short this whole question of truth telling seems to me to depend upon the temperament and the mental state of a patient. No single categorical rule can be laid down, we have to trust our instinctive knowledge of human beings and be guided accordingly.

#### PROLONGATION OF LIFE AND EUTHANASIA

Regarding the first of these questions there seems to be little question. There is a point beyond which the mere artificial prolongation of the life of a body that seems marked down for death is not merely useless but also even an unkindness. One might even defend the thesis that it is a perverted conception of goodness and of ethics. When Shakespeare says, "She should have died hereafter," he meant not that her death was premature but rather that she was going to die some time and in any case

When we are actually in sight of that time it seems to be right to accept the fact. I have never come across on the part of the laity any difference of opinion about the medical conduct of a case once this situation is accepted.

The question of euthanasia is more difficult. There is, as you know, much vocal medical opinion in its favor in England. And the matter is often discussed privately here. It is an open question. As to the act itself, many a suffering person has begged for it, many kinsfolk have been willing to accept it, and I suspect that many a doctor has been sorely tempted at this point. I have a friend who, with the connivance of her doctor, gave her husband, who was suffering from a cruelly painful and fatal disease, a heavy overdose of morphine. She said she had no scruples about doing so and had never had a single regret. You must know many more such examples than I know. She was either more resolute or more fortunate than most human beings. A few years ago I watched my Scottish terrier being put away. He was old and blind and sick. But even so I didn't like it. It seemed to me that the veterinarian and I were taking a great responsibility and one perhaps to which we were not morally entitled. How much more so in the case of a human life!

If euthanasia were ever to be legalized no single medical man could be or should be empowered to make such a decision alone. A panel of doctors would probably have to be set up by the state to make any such decision. Public medicine of any kind raises all sorts of valid questions. It is not easy to foresee a panel of state officials charged with this task, nor is it easy to envisage the doctor who would accept this responsibility as the major, if not the sole, form in which he practiced his profession. Whatever the warrant of a given emergency may be, the legal validation of euthanasia seems to cut against the whole basis and practice of medicine. I suppose that none of us are 100 per cent psychologically sound, and one wonders what perversions might creep into the practice of euthanasia.

Albert Schweitzer, who is a doctor as well as a minister, and who has done such splendid work at Lambarene in West Africa, says of himself that journeying up river from the coast to his hospital on one occasion he was searching for some basic ethical principle.

Slowly we kept upstream, laboriously feeling for channels between the sand banks. Lost in thought I struggled to find the elementary and universal conception of the ethical which I had not discovered in any philosophy. Sheet after sheet I covered with disconnected sentences. Late on the third day at the very moment we were making our way through a herd of hippopotamuses, there flashed upon my mind, unforeseen and unsought, the phrase "Reverence for life." For all life.

His autobiography has many striking instances of his subsequent application of that principle.

This is, after all, the ethical basis of the practice of your profession as of my profession. If we forfeit that reverence we have slipped our moral moorings. And if in practice we violate that principle, we should know that we are doing so and take the responsibility for so doing. Once again, "Thou hast not as it were forsaken me, thou hast forsaken thyself." To forsake one's own self is an act that leaves its scars on the mind. Personally, I should question the wisdom of medicine's accepting as a principle, and the state's legalizing in practice, acts of euthanasia. Such a *volte face* in the whole conception of the aim of the profession would impair the conscious integrity of its members and would introduce in place of an accepted principle—which, if it is ever to be violated, should be violated soberly and wittingly—a state of ethical perplexity and painful indecision in which each case must be decided on its own merits. The effect on the public would be almost disastrous, since it would introduce into these relationships a sense of insecurity and apprehension, rather than confidence and assurance. If a doctor or a minister has never had, or having had has lost, his reverence for life and his feeling for the sacredness of life, he lacks that which in theory his profession presupposes. Unless you and I are to revise radically our conception of our common task, it is not our business to take life, only to try to save it.

#### RIVAL CLAIMS OF COMPETING INDIVIDUALS, OR OF THE CONCRETE INDIVIDUAL AND SOCIETY IN THE ABSTRACT

We come, finally, to the specific type of problem that was proposed to me. Here is a woman apparently dying of an inoperable and incurable cancer of the stomach. She is being kept alive by blood transfusions, but the blood that she needs is the rarest type, of which the blood bank has only a limited supply. The transfusions cannot save her. Is it not foolish, perhaps even wrong, to waste this precious blood on her? Ought it not to be kept for some later patient who may be helped by it, whose life perhaps may actually be saved by it? Or here is a man in the iron lung, who could not live an hour outside it and yet may live half a lifetime in it, to the exclusion of someone else who might be got around a bad corner and in due time dismissed. Ought he to be allowed his monopoly of this mechanism?

These are difficult, even heartbreaking questions. Either way, the choice is a genuinely tragic one. I do not know that I have sufficient wisdom to answer them. I can only fall back on general principles.

There are two terms that have been much to the front in recent years. They represent what are called social trends. One is the word "depersonalization," and the other the words "mass man." Both terms represent tendencies, particularly on the part of the state, to depreciate the value of the

single individual in favor of the group as a whole. These trends have found their fullest expression in countries where totalitarianism has been, or still is, the order of the day. In such societies the individual is of value only as a member of the mass, and is always regarded as expendable.

Our own country has just now fought two world wars in defense of the general idea of liberty and the rights of the individual. His liberties have had to be circumscribed in wartime, and now that the fighting is for the moment over, we are left with lives that are much less free, as far as our private affairs are concerned, than they were forty years ago. It could not have been otherwise, perhaps, and yet this steadily narrowing area in which anything like actual liberty and private initiative remains is one of the paradoxes of these years.

There is abroad a tendency to treat this doctrine of mass man as though it were a late discovery, the mature achievement of complex modern societies. I venture to point out that on the whole, it is the oldest of all our social theories. It was the appraisal of life current in all primitive societies. The individual mattered only as a member of the tribe, and all the tribal rites looked to his initiation into the tribe and his subsequent identification with it. This was true of the religion of the early Israelites. The single individual had no independent worth either in his own eyes or for his fellows or even to Jehovah. The doctrine of the worth and moral independence of the individual emerges only with the prophet Ezekiel after the return from the exile. This lead is taken up and matured in Christianity, which holds that "not a sparrow falls to the ground without your Father." However difficult the doctrine may be to understand and defend, such is the doctrine of later Judaism and Christianity — both have traditionally believed in the value of the individual. Our social institutions come into being to express him and to defend him. "The Sabbath was made for man, not man for the Sabbath."

This appraisal of the facts was, also, the premise of all modern democracies, our own in particular. The case has never been theoretically proved beyond all contradiction, or vindicated in the total practice of any society. It remains, in many respects, a bold ideal. But unless we repudiate our hereditary faith, both religious and political, it is still our ideal, and its denial would mean a radical change in the whole temper of our life.

The drift of the times, in the worlds of finance and industry, and in military policy, seems to be in the direction of the dogma of mass man. At their hands the individual is inevitably more or less depersonalized. Perhaps it cannot be otherwise, given the numbers of human beings involved and the complexity of most modern issues.

In any case it is left largely to two groups of professional persons, the doctor and the minister, to

vindicate a working faith in the value of the individual. Any lack of that faith on our part is tantamount to desertion of an ideal outpost that we have held in behalf of what we believed to be a valid cause.

The first social-settlement house in the English-speaking world, Toynbee Hall in East London, was presided over by a quiet little Anglican clergyman, Samuel Barnett. In her biography of her husband Mrs. Barnett says that any number of persons used to come down for a day from the West End of London to its dreary East End, with large blue-print plans for the redemption of those drab slums. They aired their plans, spent a pleasant evening with the warden and went away. Mrs. Barnett says that her husband came to the conclusion that the only permanent good ever done in the East End of London was done by those "who were willing to take time and trouble with individuals," and that this verdict upon the fact became his own rule of life.

A man who goes into the practice of medicine or of the ministry ought to enter his profession with that conviction and ought to do his best to vindicate it. There is a place in society for the man who wishes to devote his life to the general and all-over cause of public health. There is a place in the religious world for a man who feels he should sign on with one or another of the great reform movements of the time. The work of these men is necessary, and their contribution to society may be very great. But the practicing doctor and the parish minister are primarily concerned with individual human beings. The moment either begins to sacrifice his concern for the individual to some other hypothetical person, or to society in the abstract, he has mistaken his vocation.

He may justify his decision to himself on the grounds of a higher or broader loyalty, but he will have failed his cause at a point that it is more and more difficult to hold in the modern world. If he ceases taking time and trouble with a given individual on the ground that he can thus be of greater service to someone else he impairs to this extent the confidence of the community in himself and his profession. Once a man accepts the ministry of a parish he is under bonds to take time and trouble with the individuals who comprise it. Most of the failures that I know of in my own profession have been due to a neglect of that premise. If my analogy is valid I should suppose that once a doctor and a hospital have accepted a patient they are under bonds to see the patient through.

I agree that this may involve what will often seem a waste of precious time to no permanent good. But there is something more at stake here than the welfare of the single patient, there is also the confidence of the community in the integrity and single-mindedness of the profession itself. If

that confidence is impaired not merely the good name but also the actual effectiveness of the profession suffers in consequence

These are tragic choices. And as Bradley says, the essence of tragedy is the fact of waste that it involves. To know them as tragic and to feel their tragedy is perhaps half the battle at the outset. If a man cannot feel these tragedies in medicine and the ministry there is something wrong with him. If he is a sensitive man he will feel them more deeply as the years go on. He will always make his decisions reluctantly and with pain of heart, if not perplexity of mind. But he is the defender in church and state of certain basic principles of our society that he cannot forfeit without radically revising

the premises of his profession and to this extent impairing the whole tradition to which he belongs

\* \* \*

I have not answered Dr Means's problems, or yours. But I have tried to point out what some of the issues are. In so far as I have any answers they are, briefly

Tell the truth, but "tell the truth in love," and telling the truth in love may often mean silence rather than some hastily spoken word. Maintain at all times a sense of the sacredness of life.

Be willing to take time and trouble with individuals at the expense of that abstraction known as mass man.

## PROGNOSIS IN ESSENTIAL HYPERTENSION\*

### Eight-Year Follow-up Study of 430 Patients on Conventional Medical Treatment

ROBERT STERLING PALMER, M D,† DOROTHEA LOOFBOUROW, M D,‡ AND  
CARL R. DOERING, M D§

BOSTON

CONSCIENTIOUS interval evaluation of sympathectomy for essential hypertension by comparison with control material is progressively defining the limitations and the applicability of this procedure.<sup>1,2</sup> The same attention to control material is required when one considers the usefulness of very restrictive diets, interest in which has recently revived.<sup>3,4</sup> Before applying these diets generally and indiscriminately, we should ask ourselves what the remote effects will be on the body electrolyte economy, on work capacity and hot-weather tolerance, on resistance to infection, on the basal metabolism, on carbohydrate tolerance and on fetal health in pregnancy. Finally and practically, how often is an extremely irksome diet necessary in essential hypertension? If employed, does it actually prolong the life of the patient? Are most of the successes obtained in those patients likely to be matched in any case? To help answer these three important questions, adequate control material is the first necessity. This we believe we have and submit it herewith. In this series of cases, treatment consisted of the combination of physical rest and activity deemed

appropriate for each patient, sedative drugs and sometimes sulfocyanates, low-fat, relatively high-protein and low-salt diets, in exceptional cases low-sodium diets for short periods, the usual drugs for congestive or anginal failure and finally practical psychotherapy.

Originally, our series of patients with hypertension consisted of 1072 patients personally observed, the great majority of them between 1935 and 1940. After patients with transient nervous hypertension, those with glomerulonephritis, those who were sympathectomized and those inadequately followed had been excluded, 646 subjects remained. Observation comprised a careful history and physical examination, routine blood and urine examinations, a fractional intravenous phenolsulphonephthalein test, a urine concentration test, frequently intravenous urography or orthodiagram or seven-foot film of the heart and an electrocardiogram.

After the original observations and satisfactory follow-up study, these 646 patients were classified according to clinically recognizable organic changes in the three vital areas: the head, the heart and the kidneys. The classification depended upon the most marked change in the area or areas in which it was found. These criteria are presented below.

#### CLASSIFICATION

##### Grade I Changes

These patients have no changes or minimal changes in the fundi as represented by narrowing

\*From the Committee on Research in Diseases of the Autonomic Nervous System, Massachusetts General Hospital and the Harvard School of Public Health.

This study was supported by a grant from the Life Insurance Fund of America.

†Associate physician, Massachusetts General Hospital; consulting physician, Massachusetts Eye and Ear Infirmary.

‡Assistant in medicine, Massachusetts General Hospital.

§Assistant professor of biostatistics, Harvard School of Public Health; consultant, Cambridge Tuberculosis and Health Association.

of the arterioles, normal hearts or no more than prominence in the region of the left ventricle by x-ray study, no impairment of renal function by the tests used and normal urine examination or occasionally slight albuminuria and slight changes on microscopical examination of the sediment

### *Grade II Changes*

These cases include moderate organic changes in the fundi as represented by widening of the arteriolar light reflex, narrowing, caliber changes and arteriovenous compression. The heart exceptionally is normal by x-ray study and is usually prominent in the region of the left ventricle and sometimes more definitely enlarged but without functional impairment, the kidney is normal slight degrees of albumin and minimal numbers of formed elements are found in the sediment, or there may be slightly impaired function

### *Grade III Changes*

The fundi are rarely normal, usually showing arteriolar narrowing, caliber changes, wide light reflex and arteriovenous compression. Often, there are exudates and hemorrhages, the heart is often moderately to markedly enlarged, commonly with symptoms and signs of actual or impending congestive failure or symptoms of anginal failure. The urine frequently shows albuminuria and casts, and renal function is often impaired though actual failure (uremia) is not common, cerebral accidents sometimes occur (in 20 per cent of cases)

### *Grade IV Changes*

The cardinal—indeed, the obligatory—sign is edema of the optic disks, with or without exudates and hemorrhages and always with marked narrowing of the arterioles. Cardiac enlargement and congestive failure may be present, renal impairment and failure are common

It is emphasized again that classification is not based on one organ, such as the fundus, but on recognized changes in any area, and that the classification is mild (Grade I), moderate (Grade II), or severe benign (Grade III), according to the most advanced change whether in one or more areas. For instance, a patient who has had a cerebral thrombosis is placed in Grade III, though the heart, kidneys and fundi are normal, no classification higher than III is made if the kidneys are impaired, there is angina pectoris, and there are exudates and hemorrhages in the eyegrounds—that is, there may or may not be evidence that one or all vital areas are affected seriously. Grade IV or malignant hypertension is recognized by papilledema alone with or without other changes. In 95 per cent this sign indicates a rapidly progressive course to a fatal outcome. In Grades I and II patients must be observed a year or more for one to be sure that the course characteristically is progressing slowly,

if at all. In Grade III serious change is promptly recognized in fundi (exudate or hemorrhages, or both), in the cerebral circulation (thrombosis or hemorrhage) in the heart (marked enlargement, actual or impending congestive or anginal failure) and in the kidneys (significant impairment of function)

We are well aware that the outward signs are poorly correlated with the inward state in essential hypertension as in other aspects of man, but we must use the signs that we have. For this reason, any clinically observable sign of vascular change in one or more of the three vital areas is taken as indicative of diffuse vascular disease, however localized such a change may be on clinical examination. It is further assumed that the severity of recognizable organic change as defined in the classification is directly proportional to the severity of the disease process. The latter assumption in practice has proved fairly correct.

In 1942–1943 after an average four years of follow-up study of 50 per cent of the 646 cases, the mortality was 6 per cent in Grade I hypertension, 17 per cent in Grade II, 36 per cent in Grade III, and 80 per cent in Grade IV.<sup>1</sup> In 1946–1947 after another four years, 430 cases or 66.5 per cent of the 646, were followed. The mortality was 22 per cent in Grade I, 47 per cent in Grade II, 78 per cent in Grade III and 94 per cent in Grade IV. It is evident that this clinical classification of essential hypertension on the average indicates the severity of the disease in respect to survival.

The average and median duration of known hypertension in each grade of the 430 patients is given in Table 1. The known duration of hypertension in Grades I to III is longer in the living (twelve to fifteen years) than in the dead (seven to nine years) patients. This reminds us of three things that the actual onset of hypertension is hardly ever accurately determined that the prognosis varies with age and sex, and that present methods of clinical examination as employed by us differentiate patients who do well from those who do badly only by an average of each grade and not in an individual patient. In Grade IV hypertension 3 patients with papilledema have survived an average of nine years and two months. These cases are exceptional. Others have had a similar experience.<sup>5, 6</sup> The average duration in patients with Grade IV changes who died is three and one-fourth years owing to the long duration of apparently benign hypertension terminated by the malignant phase in some of these cases. The median known duration is just under one and a half years. The average duration of our own observation of these patients is a little over seven months and the median slightly more than four months. It is almost always apparent at once that the course of the disease in patients with Grade IV changes is intense and rapid. It is usually apparent in Grade

III that one is observing an end stage of a condition that has often been very slowly progressive In Grades I and II a number of interval observations of a year or more are needed to prove that the condition is slowly progressive or stationary We know of no infallible signs at a single examination in these patients with Grade I and II changes that will foretell the appearance of late Grade III or malignant Grade IV changes

The age distribution of the various grades is shown in Figure 1 By inspection, one can notice that the patients with Grade IV changes are younger than all the others and that those with Grade II and III changes are older than those with Grade I This suggests that Grade I, II, and III changes form a group of patients that represents a condition different from that of Grade IV

Table 2 shows the sex distribution and survival rates and demonstrates that in this sample there are

TABLE 1 *Average and Median Duration of Known Hypertension by Grades*

GRADE OF HYPERTENSION	DURATION	
	AVERAGE yr	MEDIAN yr
Living patients		
I	12.5	11.5
II	13.9	13.0
III	14.7	13.0
IV	9.2	—
Dead patients		
I	9.1	8.5
II	8.6	7.0
III	8.2	7.0
IV	3.2	1.4

more female than male patients with essential hypertension In Grades I and II the percentage of women is greater than that of men The reverse is true of Grade IV In Grade III the numbers are equal, but the percentage of the total number of each sex reveals 50 per cent men and 40 per cent women with this degree of hypertension In Grade IV the percentage of the total number of each sex reveals 17 per cent men and 9 per cent women This sex difference is considered significant statistically, suggesting that female patients tend to have the milder grades of this disease It is an important point also that the probability of survival for females is definitely superior — 82 per cent as compared with 66 per cent for the men in Grade I, and 57 per cent as compared with 42 per cent for the men in Grade II The probability of survival is somewhat better in Grade III (27 and 17 per cent for female and male patients, respectively) and also better in Grade IV (9 and 3 per cent each for female and male patients)

The onset and progress of organic change in essential hypertension is assumed to depend upon the duration, the persistence and the height of blood pressure To evaluate the factor of age, the age at

first known hypertension was calculated, and Grades I to III were grouped as follows twenty-nine years or less, thirty to thirty-nine inclusive, forty to forty-nine inclusive, and fifty or over The mortality and the average duration of known blood pressure were determined for each group This was not done in Group IV because the course of the disease was short at any age The results for Grades I to III for the different age groups are shown in

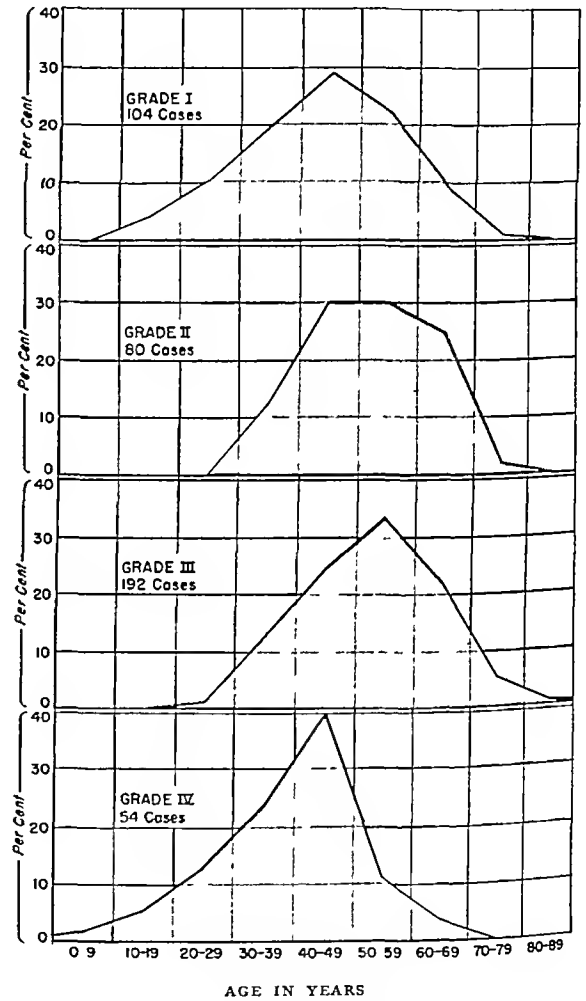

FIGURE 1 *Age Distribution by Decades*

Table 3 In these mortality figures, deaths from causes other than hypertension are excluded

From inspection of these figures it appears that an increase in age is associated with a higher mortality only in Grade I hypertension In Grades II and III the patients are older The numbers in age group twenty-nine or less are too few to be significant It is assumed that the course of the disease in many patients in Grades II and III when they were first seen was already more advanced The usually shorter known duration of hypertension in the dead patients may have been due to the cir-

cumstance that an earlier asymptomatic stage of the disease passed unnoticed. It may be that variations in the natural course of hypertension are due to constitutional, infectious, dietary, situational,

psychologic or other unknown factors that influence its progress favorably or unfavorably.

We wish to form an estimate of the prognosis of essential hypertension treated by conventional medical management based on the observation of these 430 patients followed in some cases for as long as seventeen years, some of them for shorter

III patients and the 54 Grade IV patients as 100 per cent in each grade and plotted the survival rate in per cent after four years, and again after eight years (Fig 2). The curve for Grade IV has been drawn with a steeper slope than is apparent from the four-year follow-up study. The reasons for this are that the median duration of known hypertension in this group is about one and a half years and that the median duration of our observation of this group prior to death is only slightly more than four months. If the follow-up examination had been made at two years instead of at four years, we should probably have found just a trifle larger percentage of survivors, as in the patients examined after four years.

Tentatively we have used a method of prediction that is both rough and speculative, by which one

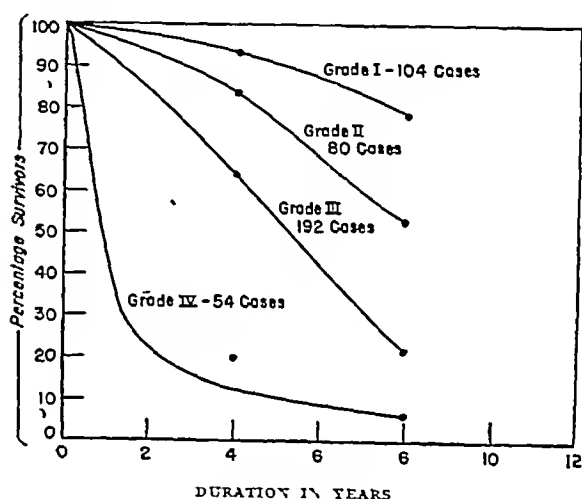

FIGURE 2 Survival according to Duration of Hypertension

TABLE 3 Mortality and Average Duration of Hypertension according to Age at Onset

AGE	MORTALITY	AVERAGE DURATION	
		LIVING PATIENTS	DEAD PATIENTS
yr	%	yr	yr
Patients with Grade I changes			
29 or less	12.5	12.5	14.0
30-39	12.0	12.8	9.0
40-49	19.0	11.1	6.2
50 and over	40.0	13.3	9.7
Patients with Grade II changes			
29 or less	—	20.0*	—
30-39	44.0	15.4	14.1
40-49	48.0	11.4	8.9
50 and over	42.0	11.9	6.6
Patients with Grade III changes			
29 or less	82.0	—†	11.3
30-39	78.5	15.6	8.7
40-49	68.0	15.8	9.1
50 and over	80.0	11.3	6.9

\*Includes only 6 patients

†Only 2 living patients, both of whom are included under group 50-59 years of age

periods, the average being eight years, and many of them with known hypertension long before our time of observation. We have taken the 104 Grade I patients, the 80 Grade II patients, the 192 Grade

might estimate the probable percentage of survivors at twelve years in Grade I as 58 per cent, in Grade II as 24 per cent, in Grade III as less than 2 per cent and in Grade IV as almost zero. Three years hence we hope to have the actual percentages.

### DISCUSSION

From our data, the quickest and clearest demonstration of the effectiveness of any therapeutic program will be to show survival of 20 per cent or more of a significant number of patients with Grade IV or malignant hypertension for five or more years. This criterion has been satisfied by Peet's<sup>7</sup> experience with dorsal sympathectomy.

The next most definite criterion of effectiveness of any given program will be to demonstrate the survival of two thirds of a significant number of patients with Grade III hypertension for more than five years.

The therapeutic effectiveness of any program in Grade I and Grade II hypertension will be doubtful until a significant number of patients have been

followed for ten years. At present we may say that considerably more than 80 per cent should be surviving after eight years in Grade I, and 60 per cent or more in Grade II to demonstrate therapeutic superiority. Consideration should be given to the sex incidence in these two grades, and allowance made for the uniformly better prognosis in female patients.

We urge that responsible clinical investigators interested in the study of essential hypertension agree upon terms and criteria for a clinically applicable classification of hypertension for the purpose of establishing the prognosis and the effectiveness of treatment in this, one of the most serious threats to life of civilized man.\*

\*The classification here used is based on that of Keith, Wagener and Kernohan,<sup>10</sup> whose work in this field since 1920, particularly in establishing the clinical syndrome of malignant hypertension is gratefully acknowledged.

## RECENT CONCEPTS REGARDING THE SPREAD AND TREATMENT OF POLIOMYELITIS\*

ROBERT B. LAWSON, M.D.†

WINSTON-SALEM, NORTH CAROLINA

THE essential questions asked about poliomyelitis today are, "How is it spread?" "How can you prevent the disease?" and "How can you cure it?" Although the answers to these questions are not known, a vast amount of knowledge about poliomyelitis, which is beginning to fit together, may furnish these answers in the next few years. At present there are glaring gaps in understanding of this disease, but the definite advances that are being made are filling some of these gaps.

### EPIDEMIOLOGY

Poliomyelitis is a worldwide disease affecting all races and classes of people. It is recognized to be most important as an epidemic disease, however, in North America, the Scandinavian countries, Great Britain and elsewhere in Europe. Until recently it was assumed to be very uncommon in the other sections of the world. Recent investigations by Paul et al.<sup>1,2</sup> have shown that, although epidemics of paralytic poliomyelitis are uncommon in the countries of the Middle East and the Far East, nonparalytic and nonepidemic infections are probably widespread in these and similar countries. This was clearly brought out by the experience of British and American troops stationed in the Middle East and Far East respectively. For, although there were only a few cases of poliomyelitis recognized in the native populations, the inci-

dence of poliomyelitis among the foreign military personnel was significantly higher than that in their home countries.

It is noteworthy that recognized epidemics are of recent occurrence and date back little more than sixty years in this country and in Scandinavia. During this period the age incidence of recognized cases has changed. Whereas the disease primarily involved infants and young children at first, there was a gradual extension into the older age groups here and in Scandinavia after the passage of years. Japan, on the other hand, had its first large epidemic in 1939 and, interestingly enough, is having the same younger age incidence that was seen in the early epidemics in the United States. Ninety per cent of the cases reported in Japan were in children under five years of age, whereas only 36 per cent of the patients were under five years in recent epidemics in this country.<sup>1</sup> It seems that there is a higher immunity in the older age groups in these native populations than is apparent in the population of the United States. This can be attributed to a more widespread dissemination of the virus in infancy in these countries, which, with the lower reported incidence of the disease, are also the countries of poor sanitation, so that it has been postulated that poor sanitation leads to wide dissemination of poliomyelitis virus among the young infants, which is not attended with a high rate of paralysis. On the other hand, as a country's sanitation is improved, it seems that more persons escape exposure to the virus in the early years and therefore remain

susceptible to a later and possibly more serious infection

The spread of poliomyelitis from patient to patient may go on by different routes. It is possible to infect experimental animals and presumably man through three routes: the nose and olfactory bulbs, the skin, and the gastrointestinal tract. It is well accepted that the usual and almost exclusive mode of entry in man is by the oropharynx through the mouth or nose. Virus leaves the human body by two routes, the oropharynx and the lower intestinal tract in the feces. Oropharyngeal swabbings contain virus in as many as 50 per cent of patients, especially for two to three days before the onset of the clinical disease to three to five days after the onset.<sup>3</sup> Stools have been found to contain virus in an even higher percentage of cases, especially in the first two weeks of the disease, but also as long as nineteen days before clinical evidence of infection<sup>4</sup> and six weeks or longer after the onset of disease in some cases.<sup>5</sup> The possible pathways of the virus from the oropharyngeal secretions or feces of the apparently healthy carrier or the clinical case to the new, susceptible person are shown in Figure 1. Virus may be transmitted directly by

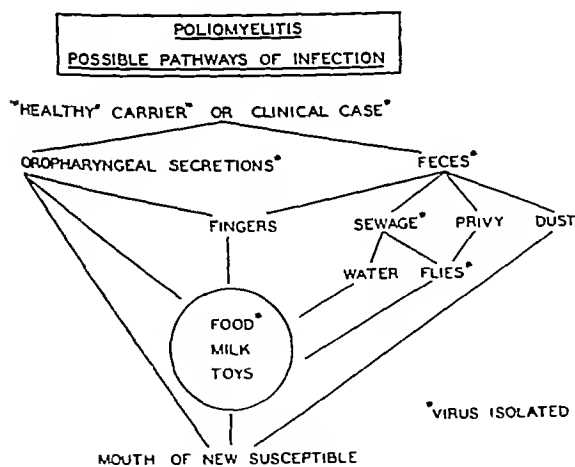

FIGURE 1

inhalation and ingestion of infected oropharyngeal droplets. Infected oropharyngeal secretions may also be passed by means of fingers and toys or food during the intimate play of children. Fecal virus may be transmitted directly as fecal dust or through the medium of toys among children, just as pinworm ova are spread so widely. Direct fecal contamination of food, including milk, may occur in the same way that typhoid spreads from a carrier, or fecal contamination of food or water may occur indirectly, transported by flies from exposed feces in privies or toilet bowls or from contaminated sewage. All these routes and others are possible and even probable, but there is no agreement on

which one is the most important in the actual transmission of the disease. The marked summer incidence of the disease and the finding of the virus in pools of flies caught during epidemics make the theory of fly transmission very attractive. I believe, however, that the fly plays only a minor role.

At present, the most convincing evidence indicates that close contact between human carriers of the virus plays the important role. During any epidemic only a small percentage of people carrying the virus are recognized since the vast majority of carriers do not have a typical illness. There is a serious lack of an easy and economical epidemiologic tool, such as the serologic tests for syphilis or the skin test for tuberculosis, that will pick up these inapparent infections. However, there are several small studies that show the importance of contact. Brown, Francis and Pearson<sup>1</sup> studied a boy's camp in Detroit after the appearance of poliomyelitis in a camper. One week after this case, they found poliomyelitis virus in the throat or feces of 5 of the remaining 7 boys in the same cabin, whereas no virus was found in the 10 boys living in the next cabin. Another interesting point was brought out — namely, that nineteen days later one of these boys carrying the virus developed typical poliomyelitis following severe exertion. A similar study was done by Gear and Mundel<sup>6</sup> in Johannesburg. After the appearance of paralytic poliomyelitis in a two-year-old child they tested the other members of the household and found virus in the stools of an eight-year-old brother. Twelve days later he developed poliomyelitis. Subsequently 2 children whom he had visited just before he became ill developed poliomyelitis, and their father had the virus in his stool. These 3 children and 12 others were at a birthday party together, of this group tests on 8 subjects revealed that 5 were harboring the virus. One of these carriers had an illness compatible with nonparalytic poliomyelitis. In summary, 1 paralytic case was followed by 3 other paralytic infections, 1 nonparalytic infection and 5 carrier states among 14 healthy contacts tested. Casey and his co-workers<sup>7</sup> have carried out extensive studies, also pointing out the importance of contact.

From these studies one can conclude that poliomyelitis virus has a world-wide distribution, that clinically recognized epidemics of poliomyelitis infections are of relatively recent origin and have been particularly prominent in the countries with high sanitation (this may mean that in countries of poorer sanitation, infections are occurring in the younger age groups with resulting immunity, but not associated with the usual signs of poliomyelitis), that close personal contact between apparently healthy carriers or clinical cases and susceptible hosts plays an important role in this widespread dissemination of the virus, and that

something happens during the summer in the temperate zones to increase this dissemination of virus (this may be explained by insect transmission, but other possibilities such as changes in the host or the virus itself may prove to be more important)

### PREVENTION

The epidemiology of poliomyelitis is important, for it leads to a discussion of prevention. The first approach is to try to prevent the dissemination of the virus. Although the most important pathway of infection is not known, the foregoing discussion suggests certain steps to minimize the transfer of the virus. Ordinary contact in schools, movies and churches may play some role, but intimate contact between children during epidemics appears to be the most dangerous factor in the spread of the virus, and should be reduced to a minimum. Foods commonly eaten raw should be washed, and all milk should be pasteurized. In addition, the possibilities of transfer of virus by flies should be minimized by fly-abatement programs and screening of all food in stores, restaurants and kitchens. Screening flies away from exposed feces in privies and toilets should be done, and further studies should be encouraged on ways to inactivate the virus present in sewage.

The second approach is to try to reduce the number of paralyzing infections among susceptible persons who have become carriers of the virus. There is evidence that exhaustion, severe chilling, coincident gastrointestinal infections and operations on the nose and throat may make the difference between a carrier state, or nonparalytic infection, and a case of paralysis. For this reason these conditions should be avoided during epidemic periods.

The third approach is to produce artificial immunity to poliomyelitis. Because of ignorance of the exact mode of transmission of the virus and because of the practical difficulties of applying what is known about it, the immunization of children against poliomyelitis is the greatest need in this field. Attempts in the past have met with failure either because the vaccines used did not produce immunity or because they were too dangerous by reason of containing live virus. New approaches to this problem are being made, and a satisfactory vaccine may be developed. If it can be proved that the people of the more unsanitary countries actually acquire immunity without demonstrable infection from exposure to the virus in early infancy, this may lead to an immunization procedure by the oral administration of virus. This idea has appealed to many people, but obviously it cannot be undertaken lightly.

### TREATMENT

The treatment of poliomyelitis is still hampered by the lack of a specific viricidal agent. The temporary popularity of serum from convalescent

patients has waned, and few people believe that it has any beneficial effect. In the present state of ignorance the treatment resolves itself around nonspecific measures aimed at the relief of complications during the acute stage, making the patient comfortable, limiting spasm and contracture of the muscles, muscle re-education and the correction of resulting deformities.

Almost all the deaths from poliomyelitis are due to bulbar or respiratory involvement so that improved treatment for this form of the disease is particularly important. Some of these deaths have resulted from complicating pneumonia, which may be prevented or treated by the judicious use of chemotherapy or antibiotic therapy (sulfonamides, penicillin). The early recognition and treatment of atelectasis may prevent some of the deaths. A more recent development is the early use of tracheotomy and oxygen therapy in selected cases described by a team of workers at the University of Minnesota,<sup>8</sup> who have shown that many patients with bulbar involvement have difficulty getting a good respiratory exchange even in the respirator. By the use of tracheotomy, alone or in conjunction with the respirator, and by the liberal use of oxygen they believe that they have pulled many patients through who would otherwise have died. Their criteria for tracheotomy were "Respiratory distress as evidenced by recurrent cyanosis, coarse rales in the chest and laryngeal stridor, excitement and unmanageability causing the patient to resist pharyngeal aspiration, stupor of a degree sufficient to make the patient oblivious of the accumulation of secretion in his airway, inability to cough effectively, pharyngeal pooling of mucus, vocal cord paralysis (or intralaryngeal hypesthesia demonstrable by laryngoscopy)."<sup>9</sup>

Another annoying and occasionally serious complication is paralysis of the bladder. Recent experience has shown that most of these patients can be relieved by the use of one of the new parasympatheticomimetic drugs, furmethide (furfuryltrimethylammonium iodide).<sup>10</sup> This is given subcutaneously in doses of 1.5 to 5.0 mg according to age, and is usually followed by voiding in five to ten minutes. The drug may have to be repeated, but spontaneous voiding is usually re-established after the first dose. In a short series of cases it has been found that catheterization, with its discomfort and attendant danger of urinary infection, can be avoided in the majority of cases.

The main treatment of poliomyelitis is symptomatic and at present is usually some modification of the Kenny technic. It is not necessary to dwell on Miss Kenny's theories regarding the therapy that she has gradually evolved, for these theories are not accepted as being tenable.

It has been pointed out that all her therapeutic measures of positioning in bed, hot applications and early muscle re-education have been described

before and used extensively in one clinic or another. It is not fair to Miss Kenny, however, to claim that nothing is new in her scheme of treatment, for it is quite apparent that these methods had given way in previous years to prolonged immobilization in splints or casts, followed by late muscle re-education. A few physicians never adopted the prolonged use of casts and splinting, but the majority had done so before Miss Kenny's appearance. Now very little of this type of immobilization is being practiced.

The chief differences in the Kenny regime and so-called "orthodox" treatment are that muscle re-education, including passive motion of the extremities, is started earlier in the Kenny program, that immobilization is much more complete in the "orthodox" method, and that Miss Kenny treats contractures by application of heat and tendon stretching rather than by corrective appliances.<sup>11, 12</sup>

There are many minor variations in the technique of treatment, of course, but it does not seem that many of them are important. Many different methods of treatment between these two extremes have been used for the past thirty years. Some men carried out a program of treatment very similar to Miss Kenny's for years before her advent. At the present time most medical centers have adopted treatment schemes that are very similar to the Kenny method, without its rigid barriers to modification.

It is of interest to compare, if possible, the results of treatment by these various methods. One cannot be dogmatic about such a comparison, for each investigator has a different method of evaluating results. However, a review of all the available articles that include specific figures shows very similar therapeutic results. Mortality rates over the past thirty years have varied, and there has been some variation in end results, but there appears to be no really significant difference in results obtained by the various methods.<sup>13</sup>

The first fairly satisfactory statistics from the Kenny Institute fail to prove any superiority for this method of therapy. I for one, however, would not go back to the period of long immobilization in casts. It is impossible to agree with Miss Kenny's pseudoscientific reasoning, but it does seem that her method of treatment is more comfortable for the patient and probably makes the recovery of muscle function easier, since the peripheral tissues are kept in better tone.

The only other new developments in therapy during the past few years have been the use of prostigmine and curare for the relief of muscle spasm. In the absence of proved value the latter is too dangerous for use at the present time, although it does warrant further study. The value of prostigmine also is not well proved. Because of the variability of this disease, many better controlled studies will have to be made before one can assess the worth of either of these drugs. Fortunately, most children with poliomyelitis will escape paralysis regardless of the method of treatment employed, and even those who are paralyzed will improve their muscular co-ordination and efficiency if treated over long periods by experienced personnel.

### CONCLUSION

In conclusion it may be noted that the picture is confused, but it is getting clearer. Newer theories regarding epidemiology, prevention and therapy have the support of well controlled clinical observation and experimentation. The outlook is better already, and investigators may well be on the brink of new discoveries that will allow conquest of this disease.

Some of these deaths have resulted from complicating pneumonia, which may be prevented or treated by the judicious use of chemotherapy or antibiotic therapy (sulfonamides, penicillin). The early recognition and treatment of atelectasis may prevent some of the deaths. A more recent development is the early use of tracheotomy and oxygen therapy in selected cases described by a team of workers at the University of Minnesota,<sup>8</sup> who have shown that many patients with bulbar involvement have difficulty getting a good respiratory exchange even in the respirator. By the use of tracheotomy, alone or in conjunction with the respirator, and by the liberal use of oxygen they believe that they have pulled many patients through who would otherwise have died. Their criteria for tracheotomy were "Respiratory distress as evidenced by recurrent cyanosis, coarse rales in the chest and laryngeal stridor, excitement and unmanageability causing the patient to resist pharyngeal aspiration, stupor of a degree sufficient to make the patient oblivious of the accumulation of secretion in his airway, inability to cough effectively, pharyngeal pooling of mucus, vocal cord paralysis (or intralaryngeal hypesthesia demonstrable by laryngoscopy)."<sup>9</sup>

Another annoying and occasionally serious complication is paralysis of the bladder. Recent experience has shown that most of these patients can be relieved by the use of one of the new parasympatheticomimetic drugs, furmethide (furfuryltrimethylammonium iodide).<sup>10</sup> This is given subcutaneously in doses of 15 to 50 mg according to age, and is usually followed by voiding in five to ten minutes. The drug may have to be repeated, but spontaneous voiding is usually re-established after the first dose. In a short series of cases it has been found that catheterization, with its discomfort and attendant danger of urinary infection, can be avoided in the majority of cases.

The main treatment of poliomyelitis is symptomatic and at present is usually some modification of the Kenny technic. It is not necessary to dwell on Miss Kenny's theories regarding the therapy that she has gradually evolved, for these theories are not accepted as being tenable.

It has been pointed out that all her therapeutic measures of positioning in bed, hot applications and early muscle re-education have been described

dentally at the age of 44, was the darkest of the family, but so far as is known he was not diabetic.

Physical examination revealed a bronze-gray cast of the exposed areas, the unexposed portions showing merely a peculiar dirty-blue pallor. The scleras were white. The mucosas were normal. The retinas were not remarkable. Occasional extrasystoles were noted, but the heart tones were of good quality. The liver was firm, smooth and nontender. It was enlarged four fingerbreadths and presented a rounded edge. The tip of the spleen was palpable. Angiomas and xanthomas were not present. The axillary and pubic hair were normal, but the genitalia showed mild atrophy. The rectal sphincter tone was good, and the prostate normal. Pedal pulses were present.

The blood pressure was 120/80.

The laboratory procedures are best enumerated as functional groups.

**Hepatobiliary system.** The albumin-globulin figures were 3.8:3.2 gm. The alkaline phosphatase was 10.2 Bodansky units. The cephalin flocculation was + + +, and the thymol turbidity, 0 units. The prothrombin time was normal. The bromsulfalein test, 5 mg per kg of body weight per 45 minutes, showed about 10 per cent retention of the dye (serum, opaque), the total cholesterol was 208 mg, and the cholesterol esters, 68 mg per 100 cc. The total serum lipids were 1057 mg per 100 cc, and the lipochrome index, 26 units. A Graham-Cole test showed nonvisualization

FIGURE 3 Liver Needle Section, Showing Hemochromatotic Cirrhosis (Low-Power, Hemosiderin and Eosin Stain)

of the gallbladder after the administration of nine "prodax" tablets. Duodenal drainage then revealed normal "A" bile, but "B" bile could not be obtained.

**Pancreas.** Pancreatic lipase and amylase were present in normal amounts in the duodenal contents. The stool fat and fatty acid content was not abnormal (Sudan III). Fatty acid crystals were not seen, nor were undigested fibers observed.

**Kidneys.** Urinalysis showed a trace of protein, but no formed elements. The urine concentration reached 1015 after 15 hours' abstinence from fluids. The phenolsulfonephthalein excretion after adequate fluids was 40 per

cent in 15 minutes, and totaled 50 per cent at the end of 2 hours. The serum phosphorus was 3.6 mg, and the blood urea nitrogen, 14 mg per 100 cc.

**Adrenal glands.** The serum sodium was 318 mg, and the serum potassium, 11.4 mg per 100 cc. A Kepler-Power water test<sup>6</sup> showed a night volume of 280 cc, the largest hourly day specimen measuring 90 cc. The quotient, how-

FIGURE 4 Portion of the Liver Needle Section, Showing Hemosiderin Granules within the Liver Cells, the Bile-Duct Epithelium and the Fibrous Stroma (High-Power, Ferrocyanide Technique)

ever, was 30 according to Procedure II and, therefore, negative.

**Hematopoietic system.** The hematocrit was 40 per cent. The red-cell count was 3,800,000, and the hemoglobin 11.2 gm (photometric technique). No macrocytosis was evident. The gastric contents were acid after histamine. Bone-marrow smears obtained from the iliac crest showed a marked increase in erythropoiesis, mild myeloid maturation arrest and hemosiderosis of fixed cells. Pathological sections of the clotted marrow showed that it was moderately fatty. Increased amounts of hemosiderin were present within the reticular and the sinus epithelial cells (Fig. 1).

A skin biopsy obtained from the dorsum of the hand revealed slight to moderate amounts of hemosiderin about the sweat glands (Fig. 2).

Liver needle biopsy showed a well established portal cirrhosis with moderate bile-duct proliferation. Abundant pigment was present within the fibrous stroma, and smaller amounts were found within the hepatic cells proper, as well as within the bile duct epithelium (Fig. 3 and 4). No active degenerative changes were evident.

The hemosiderin present in all three locations exhibited the ferrocyanide reaction characteristic for this pigment.

## DISCUSSION

The clinical picture in this case was sufficiently characteristic to make its discussion unnecessary. The lipemia, however, warrants some consideration. Since it most probably reflects primary digestive-organ impairment, the interrelated functions of the liver, the pancreas and the gastrointestinal tract are involved to a variable degree. Of course, lipemia is a feature of the nephrotic syndrome, but this need not be considered here.

The gastrointestinal tract is probably not at fault. This is a postabsorptive lipemia. As such, it is somewhat more logical to assume that this mani-

ALFRED R. LENZNER, M.D.,† AND BYRON D. BOWEN, M.D.‡

BUFFALO, NEW YORK

THE occurrence of lipemia in hemochromatosis has not been described in the literature, to our knowledge. The recognition, therefore, of an opaque serum taken from an otherwise typical patient in the fasting state was quite surprising. But so are several variants of hemochromatosis reported since Trousseau's first casual allusion to this syndrome in 1865<sup>1</sup>. For example, of the

etiology per se, they are of as much aid as those for the total iron content would be. The present circumstance, however, does give occasion for careful reconsideration of the causes of postabsorptive lipemia.

## CASE REPORT

A 56-year-old fireboat deckhand was admitted to the hospital in July, 1947, with the chief complaint of failure to gain weight. Diabetes mellitus had been diagnosed 18 months previously, after he had noted polyuria for 8 weeks. These symptoms were accompanied by a 30-pound weight loss. His physician had placed him upon 35 units of protamine insulin daily. No change in weight had followed this regimen. Four months before admission, he had entered another hospital because of painful feet and nocturia. Hepatomegaly, diabetes and pigmentation had been noted by a medical student acting as a subintern. Roentgenograms of the legs had revealed a moderate amount of arterial calcification and mild osteoporosis of the bones of the feet. The first fasting blood glucose had been 211 mg per 100 cc, a cephalin flocculation test had been ++, and the fasting serum collected

FIGURE 1 Section of Bone Marrow Aspirated from the Iliac Crest, Showing Increased Amounts of Hemosiderin in Reticular and Sinus Epithelial Cells (High-Power, Hemosiderin and Eosin Stain)

triad of cirrhosis of the liver, diabetes mellitus and pigmentation, cirrhosis only seems to be constant. In some cases diabetes has been proved not to have been present.<sup>2,3</sup> Others<sup>4</sup> have been unable to demonstrate intradermal pigment, despite apparently typical pigmentation. Moreover, the pathological physiology itself is obscure. One salient fact stands forth, however: these patients do retain abnormal amounts of iron salts.<sup>5</sup> Sheldon<sup>1</sup> has estimated that the total iron content in hemochromatosis may lie between 25 and 50 gm, as compared with a normal of approximately 3 gm.

Up to the present, figures seem to matter little. Those for the increased serum fat in this case are readily available. So far as they might indicate

FIGURE 2 Sweat Gland from the Dorsum of the Hand, Showing Hemosiderin Granules within the Basement Membrane (High-Power, Ferrocyanide Technic)

for an icteric index was reported as "too cloudy" for determination. He had remained on 35 units of protamine insulin until he was admitted for evaluation of the diabetes and other studies.

The patient related that while in high school he had been nicknamed "Gypsy", that he had frequently used argyrol swabs for "colds", but that his skin had become distinctly darker during the onset of overt diabetes. Since the insulin had been started he had regained much of his former strength, there was no nocturia, and his feet had improved. He had had loss of libido and potency for 18 months. He denied alcoholism. The family history was suggestive of hemochromatosis in that his mother had also been dark skinned, but she had died at 75 years of age. His brother, killed acci-

## THE MEDICAL EXAMINER AND THE PRACTICING PHYSICIAN\*

RICHARD FORD, M.D.

BOSTON

IN THE Commonwealth of Massachusetts, medical examiners and associate medical examiners are county officers appointed for a term of seven years for the purpose of investigating certain classes of deaths. Chapter 38 of the *General Laws* of the Commonwealth (as amended by Chapter 632 of *Acts and Resolves* of 1945) states:

When any person in the Commonwealth is supposed to have died by violence or by the action of chemical, thermal or electrical agents or following abortion, or from diseases resulting from injury or infection relating to occupation, or suddenly when not disabled by recognizable disease, or when any person is found dead, it shall be the duty of any person having knowledge of such death to notify the medical examiner of the district of the county wherein the body lies of the known facts concerning the time, place, manner, circumstances, and cause of such death. A physician who, having knowledge of such a death, fails to notify the medical examiner shall be punished by a fine of not more than one hundred dollars.

In brief, the six categories of deaths to be investigated are violent, chemical, thermal or electrical, deaths resulting from induced abortion, occupational deaths resulting from injury or infection, sudden deaths in the absence of recognizable disease, and persons found dead.

On receipt of notification of a death, there are three courses open to the medical examiner. He may decline jurisdiction over the case, referring it to the attending physician or to a board-of-health physician (if there is one) for certification regarding the cause of death. He may assume jurisdiction, scrutinize available information, make a *visu* of the body (external examination) and certify the cause of death himself. Or he may view the body and then perform an autopsy or cause one to be performed.

When may a medical examiner decline jurisdiction? He may decline when, after ascertaining the available facts, he is satisfied that the death was caused by disease not related to the six categories outlined above.

Who shall certify a death when the medical examiner declines? The attending physician shall certify if he is available and if he attended the decedent at least twice, the last visit being within two weeks before death. If the physician who attended the decedent during his terminal illness is not available or if there has been no attending physician, a board-of-health physician may certify. Thus, board-of-health physicians (in areas where they are appointed) certify the deaths of those disabled by recognized disease not related to the six categories of medical-examiner cases when the attending physician has not seen the decedent within two weeks or when he is absent. Either the mother's physician or a board-of-health physician may certify stillbirths if there has been obstetric or general medical care prior to the birth, and if there is no question of violence, illegitimacy or birth injury.

What are the rules requiring that cases be reported to the medical examiner? The rules of practice vary somewhat among the medical-examiner districts and are evolved usually by collaboration between the medical examiner and the local board of health. In most districts the following cases should be reported:

Any death thought to fall into one of the six categories established by the *General Laws*.

Any hospital death within twenty-four hours of admission.

Any hospital death when the decedent was unconscious on admission and remained so.

†Research fellow in pathology and legal medicine, Harvard Medical School; associate medical examiner, Suffolk County.

festation reflects an inadequacy of assimilation rather than excessive absorption. Before assaying the contributory roles of the liver and the pancreas, however, an examination of the physical and chemical characteristics of this lipemia may be helpful.

The term "lipemia" as it is used here is a clinical one—that is, it refers to visible amounts of fat in the fasting serum or plasma. The opacity is due to fats in their neutral phase. According to Thannhauser,<sup>7</sup> this is usually but not necessarily always accompanied by hypercholesteremia. Conversely, markedly elevated serum cholesterol and phospholipid levels are exhibited in the perfectly transparent serums of patients with primary biliary "xanthomatous" and cholangiolitic types of cirrhosis. These patients do not have lipemia, however, for their neutral fats are normal in amount. In this case excess neutral fats were not accompanied by an increase in either phospholipids or cholesterol (Table 1).

This fat pattern is a key consideration. It immediately eliminates idiopathic hyperlipemia,

TABLE 1 Serum Fat Analysis \*

	PATIENT mg per 100 cc	NORMAL CONTROL mg per 100 cc
Total fatty acids	599	200-400
Neutral fat	370	0-150
Total phospholipids	151	150-250
Total cholesterol	219	150-260
Cholesterol esters	139 (64%)	70% of total

\*Reported through the courtesy of Dr. Siegfried J. Thannhauser of Boston.

which is characterized by elevated cholesterol and phospholipid levels, in addition to the high neutral fats shown here.

The liver, moreover, is apparently not the prime mover in this lipemia. For although previous laboratory data had shown hepatic dysfunction, the essentially normal phospholipid, cholesterol and cholesterol-ester relations indicated that the hepatic phase of fat metabolism was unremarkable. Man et al.<sup>8</sup> concluded from similar fat studies that a "hypolipemia" usually exists in cirrhosis. The neutral fat seldom exceeded the upper limit of normal, the cholesterol and lipid phosphorus were either normal or decreased, and the cholesterol esters were often decreased. Aside from the pigment present in this liver, the process here is identical with that in Man's cases, and should not per se produce a hyperlipemia of this type. Although some of Thannhauser's cases exhibited mild elevations of neutral fat, these apparently occurred with depressed hepatic function, as shown by manifestly poor cholesterol esterization. Such a depression of function was not observed in the case reported above.

The pancreas, however, may be responsible for this lipemia, by virtue of either islet-cell or even acinar-cell dysfunction. Primary diabetes under control should not logically produce a persistent

postabsorptive neutral hyperlipemia. Man and Peters<sup>9</sup> concluded that "abnormalities of the serum lipoids are related loosely, if at all, to diabetes." When lipemia and hypercholesteremia did occur, these could not be correlated with the "inherent severity of the (islet cell) disease as measured by any recognized criteria." Alloxan diabetes in rabbits<sup>10</sup> and in dogs,<sup>11</sup> moreover, when controlled by insulin, failed to produce a hyperlipemia (total serum lipids). But high lipids and cholesterol accompanied fatal alloxan diabetes in all of Kendall's<sup>12</sup> animals.

The patient in the case reported above is a "fragile" diabetic. On 50 units of protamine zinc insulin daily his blood glucose levels have always been low (less than 100 mg per 100 cc), with rather high postprandial values (more than 240 mg per 100 cc) and glycosuria. There has been no ketosis, however, and the transiently elevated glucose levels should not furnish cause for this lipemia. He has never exhibited clinical shock. Islet-cell diabetes, therefore, does not strike one as being the causative agent here.

Finally, the acinar tissue of the pancreas should be mentioned. The presence of adequate duodenal pancreatic ferments, together with normal stool findings, seems to absolve the acini. Perhaps these tests are too gross for this type of disease. Nevertheless, even the technic of Bauman and Whipple<sup>13</sup> proved more helpful in obstructive pancreatic disease than in the sclerosing type characteristic of hemochromatosis. The evidence against the pancreatic acini is only circumstantial, to be sure, and yet one has the feeling that the pancreas is more guilty than the liver in this case.

Most studies of the pancreas in fat metabolism mention fat accumulations in the liver. It should be pointed out that the remaining liver parenchyma and its regenerates here are not fatty. This is true despite the lipemia and probably pancreatic insufficiency—a combination that might be considered ideal for the production of fatty liver. Here, as also in "idiopathic hyperlipemia," the liver is kept free from fat accumulations in an "environment of plenty," so to speak. One cannot, therefore, identify the specific reason for this lipemia with certainty.

At present, more than two years since his diabetes was first discovered, and despite a gradually increasing lipemia, the patient works every day. The fasting urine remains sugar free on 50 units of protamine zinc insulin. But the underlying lesion apparently continues unabated, for a dermal scar at the site of the liver biopsy has developed the gun-metal pigmentation often associated with hemochromatosis.

#### SUMMARY

A case of lipemia associated with hemochromatosis is reported. Skin biopsy, liver needle sections

An almost equally important function is to assist in the protection of public health from epidemic disease and industrial hazards. An incidental function is to investigate and furnish official records of deaths resulting from trauma of any sort, thereby protecting the rights of employee and employer, policyholder and insurer, civil claimant and defendant in all claims and suits for damages.

In metropolitan areas friction sometimes exists between the resident staffs of the hospitals and the medical examiner's office. It is apparently the firm belief of many of the younger physicians that the medical examiner acts in an ignorant, capricious and indifferent manner, especially with respect to performing autopsies. It is hoped that the exposition of the duties and limitations of power of the office presented above may eliminate this impression. Such critics, if they grant that the medical examiner must certify the cause and manner of death of certain cases without the right to autopsy, complain that bodies are removed from the hospitals by the medical examiner merely for viewing at a mortuary or undertaking establishment without allowing medical attendants the opportunity to seek permission for post-mortem examination by the hospital pathologist. The major cause for removal of bodies solely for view is the inadequacy of information furnished by the hospital to the medical examiner. Frequently, when the reporting hospital is unavoidably limited in information the medical examiner's office must seek out police reports or the records of other hospitals, or per-

haps initiate a police investigation. In the interim, after enduring delays due to locating witnesses and reaching hospital record rooms (open from 9 in the morning to 5 in the afternoon except Saturday afternoon and Sunday), the family has selected an undertaker, and the medical examiner has no right to delay the funeral further to enable the attending physicians to have additional time to solicit permission for autopsy. Sometimes the co-ordination between the administrative and professional staffs of a given hospital is at fault. A case may be declined by the medical examiner and the administration of the hospital notified, but no word is sent to the professional staff that the way is open to request permission.

Often there are limits to the physical capacity of the medical examiner to fulfill his prescribed duties. If during a twenty-four-hour period 10 medicolegal deaths are reported, with between 1 and 5 autopsies necessary in the public interest, it is obviously impossible to travel from place to place to view bodies under trying circumstances. There is, however, a solution to the difficulty. If each hospital were to designate a single physician with the experience and authority necessary to ensure complete and accurate reporting of medicolegal deaths and to facilitate the prompt viewing of bodies at the hospital, more cases would be available for hospital autopsy. No medical examiner, pathologist or general practitioner will deny that autopsy is desirable for the common good.

Any death pronounced by a physician other than the attending physician

Any death when the patient was not attended by a physician within two weeks

All such cases should be reported, but many will be declined at the time of reporting, and others after a preliminary investigation. For example, a man who collapsed at home or in his office and died fifteen minutes after hospital admission may be found to have been treated by the referring physician for a myocardial infarction five days previously. In another case in which a woman dies within twenty-four hours of admission to a hospital in coma the medical examiner may infer from the excessive obesity of the patient, from a positive history of hypertension and from a negative history of trauma that death was due to natural causes. Such cases may be declined by the medical examiner if he is satisfied that there are no reasonable grounds for suspecting that the death was caused or contributed to by physical or chemical injury or occupation.

What is the limit of time between injury and death within which a death must be reported to the medical examiner? There are no limits if the reporting physician believes that the injury caused or contributed to the death. Although the passage of time between injury and death may eliminate criminal responsibility, prevent tort action (damage suit) and make insurance claims contestable, intricacies of law, as when the damage was recognized, make it imperative that the medical examiner make an official record of the circumstances. Where there is not a clearly demonstrable relation between injury and death, the medical examiner may apply the British rule and decline such cases having a time interval in excess of a year and a day.

When may a medical examiner perform an autopsy? According to Chapter 38 of the *General Laws*, as amended

If on view of the dead body and after personal inquiry into the cause and manner of death, the medical examiner considers a further examination necessary in the public interest [he] on his own authority may make or cause to be made in his presence, an autopsy on the aforesaid body

In other words, medical examiners are required to perform an autopsy only if it appears to be necessary in the public interest. A death that is a police matter is apt to require post-mortem examination, either to exonerate a suspect or to substantiate a suspicion. In general, cases likely to reach the criminal courts require autopsy. A death thought to be the result of virulent contagious disease may well require post-mortem confirmation because of the possible hazard to public health. A death related to occupation in industry, as a result of either injury or infection, may require autopsy

in the public interest if others in that industry are exposed to the same hazard. Post-mortem examination of the body of an unknown person found dead may be desirable first, to determine the cause of death and, second, to provide information about the presence of chronic disease, the nature of past surgical procedures, old injuries, and any other anatomic fact that might add to the description of the unknown.

When the circumstances have established that an autopsy may reasonably be required in the public interest, the second criterion should be met—namely, that post-mortem dissection is necessary to establish either cause or manner of death. The body of a man who was seen by reliable witnesses to slip, fall and strike his head and who subsequently died in a hospital with x-ray films showing extensive fractures of the skull does not ordinarily require autopsy. If, on the other hand, a man were found unconscious on the street and subsequently died in a hospital without regaining consciousness and with signs of severe head trauma it would be necessary to perform a postmortem examination to determine to the fullest extent the nature of the injuries. Thus, it is in the public interest to establish whether there was one or multiple impacts, the size and the shape of the object that produced injury, and the presence or absence of disease or intoxication that may have predisposed the deceased to accident or assault. In essence, then, an official autopsy is necessary in cases in which precise detail regarding cause is of value, such as those destined for criminal courts, those in which the manner of death may be ascertained in part or in entirety by determination of the nature of injuries and those in which information contributing to identification may be acquired.

Under certain circumstances a medical examiner is required to perform an autopsy when so instructed

[The medical examiner] if he be so requested by the district attorney or the attorney general, shall make or cause to be made in his presence, an autopsy on the aforesaid body. Upon written order of the district attorney of the district where the body lies, or of the attorney general, a medical examiner shall also make, or cause to be made in his presence, an autopsy of any dead body within this county.

In simpler wording, on request—verbal or written—of either the attorney general or the district attorney, a medical examiner is required to perform an autopsy.

It should now be clear that a medical examiner does not act according to whim. He declines jurisdiction, or accepts and views a case, or performs an autopsy according to certain rules, which are derived from the *General Laws* of the Commonwealth. The most important function of the medical examiner is to protect the public by the acquisition of accurate medical evidence in deaths known or suspected to have resulted from criminal action.

An almost equally important function is to assist in the protection of public health from epidemic disease and industrial hazards. An incidental function is to investigate and furnish official records of deaths resulting from trauma of any sort, thereby protecting the rights of employee and employer, policyholder and insurer, civil claimant and defendant in all claims and suits for damages.

In metropolitan areas friction sometimes exists between the resident staffs of the hospitals and the medical examiner's office. It is apparently the firm belief of many of the younger physicians that the medical examiner acts in an ignorant, capricious and indifferent manner, especially with respect to performing autopsies. It is hoped that the exposition of the duties and limitations of power of the office presented above may eliminate this impression. Such critics, if they grant that the medical examiner must certify the cause and manner of death of certain cases without the right to autopsy, complain that bodies are removed from the hospitals by the medical examiner merely for viewing at a mortuary or undertaking establishment without allowing medical attendants the opportunity to seek permission for post-mortem examination by the hospital pathologist. The major cause for removal of bodies solely for view is the inadequacy of information furnished by the hospital to the medical examiner. Frequently, when the reporting hospital is unavoidably limited in information the medical examiner's office must seek out police reports or the records of other hospitals, or per-

haps initiate a police investigation. In the interim, after enduring delays due to locating witnesses and reaching hospital record rooms (open from 9 in the morning to 5 in the afternoon except Saturday afternoon and Sunday), the family has selected an undertaker, and the medical examiner has no right to delay the funeral further to enable the attending physicians to have additional time to solicit permission for autopsy. Sometimes the co-ordination between the administrative and professional staffs of a given hospital is at fault. A case may be declined by the medical examiner and the administration of the hospital notified, but no word is sent to the professional staff that the way is open to request permission.

Often there are limits to the physical capacity of the medical examiner to fulfill his prescribed duties. If during a twenty-four-hour period 10 medicolegal deaths are reported, with between 1 and 5 autopsies necessary in the public interest, it is obviously impossible to travel from place to place to view bodies under trying circumstances. There is, however, a solution to the difficulty. If each hospital were to designate a single physician with the experience and authority necessary to ensure complete and accurate reporting of medicolegal deaths and to facilitate the prompt viewing of bodies at the hospital, more cases would be available for hospital autopsy. No medical examiner, pathologist or general practitioner will deny that autopsy is desirable for the common good.

## MEDICAL PROGRESS

## BAL\*

RAYMOND V RANDALL, M D, AND ALBERT O SEELER, M D †

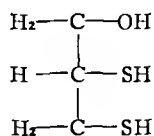

BOSTON

THE discovery of BAL (2,3-dimercaptopropanol) by Peters and his co-workers<sup>1</sup> in England was the result of an intensive search for a substance that would be effective in treating severe burns caused by contact with certain arsenical war gases such as lewisite. The name BAL is an abbreviation of "British Anti-Lewisite," a term applied to this substance after it had proved to be effective against lewisite. It was soon found that this compound was of value not only in treating the local effects of arsenical war gases but also in combating the systemic disturbances following their absorption. Moreover, BAL proved to be effective in the treatment of toxic reaction caused by arsenical drugs used in the therapy of syphilis. Further investigation showed that the substance was of value in the treatment of poisonings from a number of other metals.

The studies on BAL and related compounds have not only led to the development of a valuable therapeutic agent but also contributed to an understanding of the mode of action of various metals.

CHEMISTRY AND PROPERTIES<sup>2-4</sup>

The chemical name for BAL is 2,3-dimercaptopropanol. It contains two thiol groups (also known as sulfhydryl [-SH] groups) and consequently 2,3-dithiopropanol is a commonly used synonym. Its structural formula is

BAL has a molecular weight of 124.2 and a specific gravity of 1.21, and is an oily, colorless liquid with a skunklike odor. In common with a number of closely related dithiols, the compound is a sluggish, nonautooxidizable, oxidation-reduction system, easily oxidized in the presence of a number of catalysts, especially copper and iron porphyrins. BAL reacts with a number of metals to form BAL-metal complexes. Colored complexes are formed with iron, lead, bismuth, tin, copper, cobalt, nickel,

antimony and selenium. Zinc, cadmium and mercury combine with BAL to give white precipitates, and magnesium and manganese form colorless, soluble complexes. BAL instantaneously converts methemoglobin to oxyhemoglobin in the presence of oxygen.

BAL is soluble in water to the extent of 6 per cent (weight/volume). Because it is readily oxidized, aqueous solutions are unstable and must be prepared immediately before use. The compound is relatively stable in peanut oil, but soluble in this vehicle only to the extent of 5 per cent (weight/volume). However, when it is mixed with benzyl benzoate in the ratio of 1 part of BAL to 2 parts of benzyl benzoate it is miscible with peanut oil in all proportions. Such preparations are homogenous but become cloudy at icebox temperatures. This cloudiness readily disappears when the preparation is warmed to room temperature. Commercial preparations of BAL contain 10 per cent BAL and 20 per cent benzyl benzoate (weight/volume) in peanut oil and are suitable for intramuscular use only. Sterilization of such preparations by autoclaving at 120°C for twenty minutes may cause the loss of as much as 15 per cent of the available sulfhydryl groups by oxidation. If, however, these preparations are placed under nitrogen they may be autoclaved without significant decomposition.

## MODE OF ACTION OF HEAVY METALS AND BAL

During the past twenty-five years, the concept has arisen that heavy metals owe their toxicity, at least in large part, to their ability to combine with sulfhydryl groups of the protein fractions of enzymes. Studies that ultimately led to this concept and to the development of BAL began in 1923 when Voegtlin, Dyer and Leonard<sup>5</sup> showed that glutathione, as well as other monothiols (substances containing one thiol or sulfhydryl group), could counteract the toxic action of arsenoxides on trypanosomes both in vitro and in vivo. They further showed that glutathione delayed the onset of symptoms and death in rats given a lethal dose of arsenoxide. On the basis of these findings, they postulated that arsenoxide could be regarded as a specific poison affecting the sulfhydryl groups of some essential protoplasmic constituent. The addition of the monothiols presumably supplied extra sulfhydryl groups, which united with and thereby counteracted the toxicity of the arsenic. The au-

\*From the Department of Industrial Hygiene, Harvard School of Public Health.

This study was aided by a grant from the Medical Advisory Committee of the American Petroleum Institute.

†Assistant professor of industrial medicine, Harvard School of Public Health.

thors also assumed that the union between the arsenic and the added sulfhydryl groups was not stable—otherwise glutathione would have prevented rather than merely delayed death in rats given lethal doses of arsenic. Further evidence of the relation of sulfhydryl groups to the toxicity of arsenic was the observation of Walker<sup>6</sup> in 1928 that *Colpidium colpoda*, a unicellular organism, could be temporarily revived after arsenic poisoning by the addition of sodium thioglycollate.

Similarity in the mode of action of arsenic, bismuth and mercury compounds was demonstrated in 1939 by Eagle,<sup>7</sup> who showed that various sulfhydryl-containing substances abolished the anti-spirochetal action in vitro of bismuth and mercury as well as of arsenic. He found that thiamine chloride and methionine, which contain sulfide (—S—) rather than sulfhydryl (—SH) groups did not have a similar inhibitory effect on these heavy metals.

Studies on proteins and enzyme systems have also been carried out in an attempt to discover the mode of action of arsenic. Szent-Györgyi,<sup>8</sup> in 1930, showed that arsenic strongly inhibited the respiration of minced liver tissue. Voegtlin, Rosenthal and Johnson<sup>9</sup> found that glutathione added to rat tissue slices prevented the reduction in oxygen consumption caused by arsenic alone. These findings also suggested that sulfhydryl groups were intimately concerned with tissue respiration, and that the action of arsenic upon living tissue was primarily through the tissue's sulfhydryl compounds. Further evidence in support of these views was forthcoming in 1932, when Rosenthal<sup>10</sup> showed that although arsenic combined with proteins containing sulfhydryl groups, it did not combine with proteins in the absence of these groups.

In the course of studies on arsenical war gases, Peters, Sinclair and Thompson<sup>11</sup> found the enzyme pyruvate oxidase to be sensitive to small concentrations of arsenic or lewisite. Since none of the coenzymes known to be concerned with the pyruvate oxidase system were sensitive to lewisite, it was concluded that the point of attack of arsenic was upon a protein component of the enzyme system. It was soon demonstrated that a protein containing sulfhydryl groups was essential for the function of pyruvate oxidase and that blockage of these groups would inactivate the enzyme.<sup>12</sup> These findings indicated that the toxic action of arsenic was due, not to some nonspecific denaturant or coagulant effect upon cellular constituents, but to enzyme inhibition.

In contrast to the work mentioned above, wherein it had been found that monothiol afforded protection against various arsenic compounds, Sinclair (as quoted by Peters et al.<sup>11</sup>) found that monothiols, even when present in large excess, failed to protect pyruvate oxidase from the toxic action of lewisite. It, therefore, seemed important to re-

investigate the nature of the union between arsenic and protein sulfhydryl groups. Since it was impossible to obtain an arsenic-sensitive enzyme, such as pyruvate oxidase, in a purified state, Stocken and Thompson<sup>13</sup> studied kerateine, a derived protein containing many sulfhydryl groups. They found that at least 75 per cent of the arsenic in the lewisite-protein complex was in combination with two sulfhydryl groups. Additional findings made it seem probable that the arsenic had combined with two sulfhydryl groups closely placed on the same protein molecule to form a ring. On physicochemical grounds it was predicted that

FIGURE 1 Ring Structure FIGURE 2 Open-Chain Structure

a ring compound (Fig 1) would be more stable than an open-chain structure formed by the union of arsenic with two monothiol molecules (Fig 2). On the basis of this reasoning, it appeared that a substance capable of competing successfully with tissue proteins for arsenic must also be capable of forming a ring compound as stable as, and preferably more stable than, that formed between arsenic and the proteins. Supporting this view was the work cited above<sup>5-7</sup> showing that monothiols delayed but did

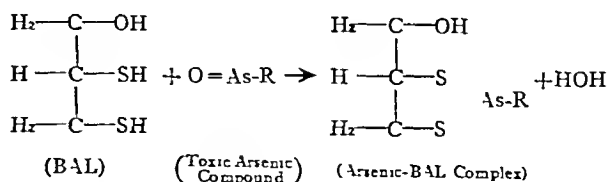

FIGURE 3 Reaction Between Arsenic and BAL

not always prevent the death of animals poisoned with arsenic.

Stocken and Thompson<sup>14</sup> decided to experiment with various dithiols because they believed that these compounds with their two sulfhydryl groups might be capable of forming stable cyclic combinations with arsenic. Numerous dithiols were tested, some with as many as 12 carbon atoms between the two sulfhydryl groups, and a number were found to react with arsenic to form a stable ring structure. However, not all the latter compounds were satisfactory on pharmacologic grounds, and it was only after extensive animal studies that BAL was selected as the most promising compound.

Further investigation showed that the substance was of value in the treatment of poisonings from a number of other metals.

The studies on BAL and related compounds have not only led to the development of a valuable therapeutic agent but also contributed to an understanding of the mode of action of various metals.

#### CHEMISTRY AND PROPERTIES<sup>2-4</sup>

The chemical name for BAL is 2,3-dimercaptopropanol. It contains two thiol groups (also known as sulfhydryl [-SH] groups) and consequently 2,3-dithiopropanol is a commonly used synonym. Its structural formula is

BAL has a molecular weight of 124.2 and a specific gravity of 1.21, and is an oily, colorless liquid with a skunklike odor. In common with a number of closely related dithiols, the compound is a sluggish, nonautoxidizable, oxidation-reduction system, easily oxidized in the presence of a number of catalysts, especially copper and iron porphyrins. BAL reacts with a number of metals to form BAL-metal complexes. Colored complexes are formed with iron, lead, bismuth, tin, copper, cobalt, nickel,

antimony and selenium. Zinc, cadmium and mercury combine with BAL to give white precipitates, and magnesium and manganese form colorless, soluble complexes. BAL instantaneously converts methemoglobin to oxyhemoglobin in the presence of oxygen.

BAL is soluble in water to the extent of 6 per cent (weight/volume). Because it is readily oxidized, aqueous solutions are unstable and must be prepared immediately before use. The compound is relatively stable in peanut oil, but soluble in this vehicle only to the extent of 5 per cent (weight/volume). However, when it is mixed with benzyl benzoate in the ratio of 1 part of BAL to 2 parts of benzyl benzoate it is miscible with peanut oil in all proportions. Such preparations are homogenous but become cloudy at icebox temperatures. This cloudiness readily disappears when the preparation is warmed to room temperature. Commercial preparations of BAL contain 10 per cent BAL and 20 per cent benzyl benzoate (weight/volume) in peanut oil and are suitable for intramuscular use only. Sterilization of such preparations by autoclaving at 120°C for twenty minutes may cause the loss of as much as 15 per cent of the available sulfhydryl groups by oxidation. If, however, these preparations are placed under nitrogen they may be autoclaved without significant decomposition.

#### MODE OF ACTION OF HEAVY METALS AND BAL

During the past twenty-five years, the concept has arisen that heavy metals owe their toxicity, at least in large part, to their ability to combine with sulfhydryl groups of the protein fractions of enzymes. Studies that ultimately led to this concept and to the development of BAL began in 1923 when Voegtlin, Dyer and Leonard<sup>5</sup> showed that glutathione, as well as other monothiols (substances containing one thiol or sulfhydryl group), could counteract the toxic action of arsenoxides on trypanosomes both in vitro and in vivo. They further showed that glutathione delayed the onset of symptoms and death in rats given a lethal dose of arsenoxide. On the basis of these findings, they postulated that arsenoxide could be regarded as a specific poison affecting the sulfhydryl groups of some essential protoplasmic constituent. The addition of the monothiols presumably supplied extra sulfhydryl groups, which united with and thereby counteracted the toxicity of the arsenic. The au-

†Assistant professor of industrial medicine, Harvard School of Public Health.

blood pressure is common, but this soon gives way to vascular collapse<sup>22</sup>

Undiluted BAL applied directly to the skin and mucous membranes causes localized redness, edema and capillary injury<sup>23, 24</sup>

Electroencephalograms taken during BAL-induced convulsions in rabbits have revealed that they are not cortical in origin. Studies following transection of the thoracic cord further showed that the convulsions do not arise in the cord. The exact site of origin has not been established. Sodium pentobarbital controlled these convulsions, but death from vascular collapse usually occurred<sup>22</sup>

In moderate doses, BAL is a respiratory stimulant. Large doses stimulate respiration initially, but severe depression of the respiratory center follows<sup>22</sup>

BAL causes an initial arteriolar constriction resulting in a rise in blood pressure. This effect is not mediated through the central nervous system, but is the result of a direct action upon the vessel walls. Subsequently, BAL may cause extensive capillary damage, which can lead to irreversible shock<sup>25, 26</sup>

In dogs, an intramuscular, lethal dose of BAL (100 mg per kilogram of body weight) has produced early hyperglycemia with glycosuria and subsequent preterminal hypoglycemia. Convulsions occurring in these animals were not hypoglycemic because they began while the blood sugar was still elevated. Histologic examination of the liver failed to reveal any evidence of hepatic-cell damage<sup>22</sup>. However, fatty degeneration and occasional necrosis have been found in the livers of dogs given daily intramuscular doses of 15 to 30 mg per kilogram of body weight for four days<sup>27</sup>. The possibility that the clinical use of BAL might be contraindicated in some cases of hepatic damage has been raised by the finding that animals with livers damaged by carbon tetrachloride showed toxic signs after doses of BAL that were ordinarily well tolerated<sup>28</sup>. However, BAL has been used in a number of patients with so-called postarsenical hepatitis, and there is no mention of extraordinarily toxic manifestations occurring in these persons.

Although the anticoagulant effect of BAL *in vitro* is pronounced, doubling the prothrombin time of human plasma, it has not been reported to produce hemorrhagic tendencies *in vivo*. Fantl and Nance<sup>29</sup> found that rabbits given BAL intramuscularly showed no changes in prothrombin time or coagulation time.

In general, histologic studies of animals receiving both single and repeated doses of BAL have failed to reveal conspicuous morphologic changes except in those dying from acutely lethal doses. Such animals show pulmonary hemorrhages and edema, which are probably the results of the marked vascular action of BAL. Isolated instances of thickening of alveolar walls and renal tubular degeneration have been seen, but it is impossible to correlate

these rare findings with the administration of BAL<sup>22</sup>. As noted above, liver damage has been observed to follow large doses.

### *Action on Man*

All clinicians who have written about the therapeutic uses of BAL warn of the undesirable side effects that may occur. Eagle and Magnuson<sup>30</sup> have reported the incidence of toxic manifestations following the intramuscular administration of BAL to 60 normal subjects and 61 patients with arsenical poisoning. At a dose level of 2.5 mg per kilogram of body weight, less than 1 per cent of injections were followed by mild toxic signs and symptoms. At a level of 4 mg per kilogram, mild to moderate reactions were noted in about 15 per cent of cases, and at a level of 5 mg 50 to 60 per cent had reactions. Localized pain at the site of injection was not uncommon, but it was no more severe than that seen after the intramuscular administration of a number of other therapeutic agents. The usual toxic manifestations were nausea, vomiting, headache, burning sensations of the mouth and eyes, lacrimation, profuse salivation, rhinorrhea, muscular aches, tingling of the extremities, sweating of the forehead and hands, pain in the teeth, a sense of constriction in the chest, anxiety and general agitation. Transient elevation of blood pressure was common. The symptoms began about ten to twenty minutes after the injections, reached a maximum in twenty to thirty minutes, and disappeared within fifty to ninety minutes. These findings are in accord with those of Modell et al<sup>31</sup> who, in addition, observed that single doses of 8 mg per kilogram of body weight almost invariably produced marked symptomatology. They also found that doses of 5 mg per kilogram could be repeated every three hours for twenty-four hours without significant cumulative effects.

Woodruff and Kometani<sup>32</sup> reported the case of a child who received two overdoses of BAL of 25 mg per kilogram each. Thirty minutes after the first overdose the child developed anorexia, vomiting and restlessness, all subsiding in an hour. Ten minutes after the second overdose (given three hours later) examination showed cutaneous flushing, mild hyperpyrexia, tachycardia, hypertension, a generalized convulsion lasting for three minutes and coma and stupor lasting for an hour. After the coma the child appeared to be normal, and recovery was uneventful.

Localized abscesses at the site of injection occur occasionally<sup>30</sup>. They seem to occur most frequently in cases of arsenical dermatitis in which the intramuscular needles have passed through infected tissues, and, therefore, are probably the result of secondary infection rather than a direct action of BAL upon the tissues.

Application to the skin can cause varying degrees of localized reactions ranging from mild erythema

It now seems clear that the antidotal action of BAL lies in its ability to unite with arsenic to form a relatively stable cyclic compound and thus to compete successfully with the sulfhydryl groups of tissue proteins for arsenic. This action is both prophylactic and therapeutic, because BAL can unite with arsenic before it enters into combination with the tissues (Fig 3) as well as wrest arsenic away from the tissues (Fig 4).

## PHARMACOLOGY

### Action on Enzymes

In an attempt to arrive at an understanding of the toxicity of BAL, Webb and van Heyningen<sup>15</sup> studied its action on a large number of enzyme

### Absorption, Metabolism and Excretion<sup>17-21</sup>

Studies with radioactive BAL (BAL containing radioactive sulfur) have shown that it is slowly absorbed through the skin but rapidly dispersed once it penetrates the cutaneous barrier. Radioactive BAL given intramuscularly has disappeared rapidly from the site of injection, with no radioactivity remaining at the site after six hours. Within five minutes after instillation into the conjunctival sac of the rabbit, BAL has been recovered from the aqueous of the anterior chamber.

Experiments with rabbits given intramuscular injections of radioactive BAL have shown that 80 per cent of the injected BAL entered the circulation and was distributed throughout the body within

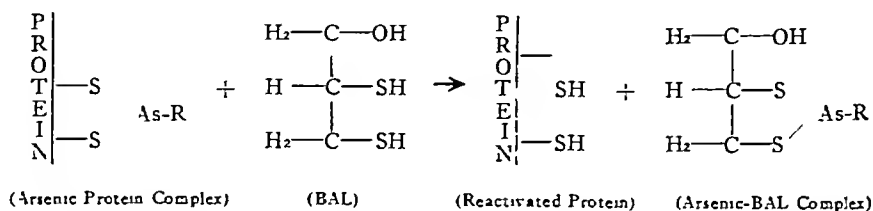

FIGURE 4 BAL Reactivation of an Arsenic-Poisoned Tissue Protein

systems. They found seven enzymes to be strongly inhibited by BAL: polyphenol oxidase, carbonic anhydrase, catalase, peroxidase, aldehyde mutase, phosphorylase and glyoxalase. Of these, four are known to be metal-containing enzymes: polyphenol oxidase (copper), carbonic anhydrase (zinc), catalase (iron), and peroxidase (iron). In view of the fact that BAL forms complexes with these metals,<sup>3</sup> it is likely that it inhibits the enzymes by combining with their metal radicals. In further support of this hypothesis is the finding that the addition of a copper salt to polyphenol oxidase inhibited by BAL restores the activity of this copper-containing enzyme. Cytochrome oxidase is the only metal-containing enzyme that was examined and found not to be inhibited by BAL. This was thought to be due to a rapid oxidation and inactivation of BAL when it comes in contact with this enzyme. No explanation is offered for the inhibition of aldehyde mutase and phosphorylase, although it is pointed out that these, too, may be metallic enzymes. It is believed that glyoxalase, which does not contain a metal but does contain glutathione (a monothiol), is inhibited by BAL, because the BAL can compete successfully with the monothiol for a position in the enzyme structure.

Barron et al.<sup>16</sup> found that BAL decreased the respiration of tissue slices and inhibited cytochrome C and succinoxidase. They also noted that BAL destroyed the activity of insulin by reduction of its —S—S— linkages.

an hour of injection. A fairly uniform blood level was maintained for two hours. This level was halved by the third hour, and fell to a third of the original value by the seventh hour. Aside from somewhat higher concentrations in the kidney and intestine, BAL was diffusely distributed throughout the body.

Only minute amounts of BAL have been found to be excreted by the respiratory tract although its skunklike odor may be detected in the expired air. Studies have shown that the major portion of absorbed BAL is rapidly metabolized and excreted in the urine. After single injections of radioactive BAL, 45 per cent of the total radioactivity could be recovered from the urine within six hours, and 81 per cent within twenty-four hours. Only a small proportion of the radioactive substances recoverable from the urine was in the form of unchanged BAL.

### Action on Animals

In general, the signs and symptoms of BAL toxicity are ushered in by an initial period of apathy accompanied by lacrimation, blepharospasm and conjunctival edema. With increasing dosage, one finds in addition to the above muscle tremors of gradually increasing intensity, inco-ordination, ataxia, especially of the hind limbs, dyspnea, and finally generalized clonic convulsions, coma and death. Only an occasional animal recovers once convulsions have begun. An early transient rise in

blood pressure is common, but this soon gives way to vascular collapse<sup>22-23</sup>

Undiluted BAL applied directly to the skin and mucous membranes causes localized redness, edema and capillary injury<sup>23-24</sup>

Electroencephalograms taken during BAL-induced convulsions in rabbits have revealed that they are not cortical in origin. Studies following transection of the thoracic cord further showed that the convulsions do not arise in the cord. The exact site of origin has not been established. Sodium pentobarbital controlled these convulsions, but death from vascular collapse usually occurred<sup>22</sup>

In moderate doses, BAL is a respiratory stimulant. Large doses stimulate respiration initially, but severe depression of the respiratory center follows<sup>22-23</sup>

BAL causes an initial arteriolar constriction resulting in a rise in blood pressure. This effect is not mediated through the central nervous system, but is the result of a direct action upon the vessel walls. Subsequently, BAL may cause extensive capillary damage which can lead to irreversible shock<sup>25-26</sup>

In dogs, an intramuscular lethal dose of BAL (100 mg per kilogram of body weight) has produced early hyperglycemia with glycosuria and subsequent preterminal hypoglycemia. Convulsions occurring in these animals were not hypoglycemic because they began while the blood sugar was still elevated. Histologic examination of the liver failed to reveal any evidence of hepatic-cell damage<sup>22</sup>. However, fatty degeneration and occasional necrosis have been found in the livers of dogs given daily intramuscular doses of 15 to 30 mg per kilogram of body weight for four days<sup>27</sup>. The possibility that the clinical use of BAL might be contraindicated in some cases of hepatic damage has been raised by the finding that animals with livers damaged by carbon tetrachloride showed toxic signs after doses of BAL that were ordinarily well tolerated<sup>28</sup>. However, BAL has been used in a number of patients with so-called postarsenical hepatitis, and there is no mention of extraordinarily toxic manifestations occurring in these persons.

these rare findings with the administration of BAL<sup>23</sup>. As noted above, liver damage has been observed to follow large doses.

#### *Action on Man*

All clinicians who have written about the therapeutic uses of BAL warn of the undesirable side effects that may occur. Eagle and Magnuson<sup>30</sup> have reported the incidence of toxic manifestations following the intramuscular administration of BAL to 60 normal subjects and 61 patients with arsenical poisoning. At a dose level of 2.5 mg per kilogram of body weight, less than 1 per cent of injections were followed by mild toxic signs and symptoms. At a level of 4 mg per kilogram mild to moderate reactions were noted in about 15 per cent of cases, and at a level of 5 mg, 50 to 60 per cent had reactions. Localized pain at the site of injection was not uncommon, but it was no more severe than that seen after the intramuscular administration of a number of other therapeutic agents. The usual toxic manifestations were nausea, vomiting, headache, burning sensations of the mouth and eyes, lacrimation, profuse salivation, rhinorrhea, muscular aches, tingling of the extremities, sweating of the forehead and hands, pain in the teeth, a sense of constriction in the chest, anxiety and general agitation. Transient elevation of blood pressure was common. The symptoms began about ten to twenty minutes after the injections, reached a maximum in twenty to thirty minutes, and disappeared within fifty to ninety minutes. These findings are in accord with those of Modell et al,<sup>31</sup> who, in addition, observed that single doses of 8 mg per kilogram of body weight almost invariably produced marked symptomatology. They also found that doses of 5 mg per kilogram could be repeated every three hours for twenty-four hours without significant cumulative effects.

Woodv and Kometani<sup>32</sup> reported the case of a child who received two overdoses of BAL of 25 mg per kilogram each. Thirty minutes after the first overdose the child developed anorexia, vomiting and restlessness, all subsiding in an hour. Ten minutes after the second overdose (given three hours later) examination showed cutaneous flushing, mild hyperpyrexia, tachycardia, hypertension, a generalized convulsion lasting for three minutes and coma and stupor lasting for an hour. After the coma the child appeared to be normal and recovery was uneventful.

Localized abscesses at the site of injection occur occasionally<sup>30</sup>. They seem to occur most frequently in cases of arsenical dermatitis in which the intramuscular needles have passed through infected tissues, and, therefore, are probably the result of secondary infection rather than a direct action of BAL upon the tissues.

Application to the skin can cause varying degrees of localized reactions ranging from mild erythema

to severe whealing and capillary damage<sup>19</sup> Sulzberger<sup>33</sup> was able to create skin sensitization with repeated applications of a 5 per cent BAL ointment to normal skin. Sixteen of 88 human subjects (19 per cent) developed localized reactions varying from faint erythema with pinhead-sized, papulo-urticarial lesions to marked erythema with confluent urticarial and papular lesions lasting up to five days. These relatively persistent lesions should be distinguished from the erythema and whealing frequently noted after topical application of BAL, which disappear in fifteen minutes to two hours. When applied to skin previously damaged by mustard gas, BAL caused a definite dermatitis in 35 out of 53 subjects (66 per cent).

Epinephrine has been used successfully to alleviate the undesirable side effects of BAL. 0.6 of 1 cc of 1:1000 epinephrine hydrochloride solution gave rapid and complete relief. Oral or parenteral administration of 25 mg of ephedrine sulfate half an hour before the administration of BAL prevented the onset of symptoms.<sup>34</sup>

### COMPOUNDS RELATED TO BAL

Although many compounds related to BAL have been studied, only two are of particular interest — namely, the ethyl ether of BAL and BAL glucoside.

The ethyl ether of BAL is more toxic than BAL. Whereas the initial toxic manifestations of this compound are similar to those produced by BAL, death, when it occurs, is not acute but is almost invariably delayed for days or weeks. Even doses forty times greater than those necessary to produce mild symptoms do not kill immediately. In spite of its comparatively great toxicity the ethyl ether of BAL is of interest because it is more effective than BAL in the treatment of arsine poisoning in animal experiments.<sup>24, 35</sup>

BAL glucoside (BAL-intrav) is much less toxic than BAL and has the advantage of being freely water soluble. Doses as large as 100 mg per kilogram of body weight have been given intravenously to man without apparent ill effects, whereas BAL itself may produce symptoms when given intramuscularly in doses of 4 mg per kilogram. Unfortunately, there are not sufficient data to permit a quantitative comparison of the therapeutic activity of BAL glucoside with BAL, but the limited information available suggests that the former has a more satisfactory therapeutic index than the latter.<sup>36-38</sup>

### BAL IN SPECIFIC POISONINGS

Although the immediate interest at the time BAL was developed was the treatment of arsenical war-gas poisoning, it soon became apparent that the compound was of value in the therapy of arsenical poisoning in general. Investigation of its value in other heavy-metal poisonings indicated that BAL could not be used indiscriminately in the treat-

ment of all because in some cases it not only was valueless but also actually appeared to enhance the toxicity of a metal. The concluding section of this progress report will be devoted to a discussion of the role of BAL in the treatment of specific metal poisonings, and mention will also be made of the effects of BAL on the action of alloxan and phenylthiourea.

(To be concluded)

### CASE 34521

#### PRESENTATION OF CASE

A fifty-five-year-old man entered the hospital because of abdominal cramps and distention.

Three weeks before admission the patient noted the gradual onset of an illness characterized by abdominal swelling and diffuse abdominal cramps. He felt bloated constantly and, in addition, had spasmodic, doubling, abdominal pains, which lasted about a minute and which he could not localize. There was a slight reduction in the number of bowel movements but no change in the character of the stools was noticed. There was no obstipation or passage of bloody, tarry or clay-colored stools. Though the patient's appetite remained good, he ate infrequently because his capacity for food was greatly reduced. A normal-sized meal nauseated him, but he never vomited. The urine was brown as it had been for several years. The legs and ankles became moderately swollen.

The patient had had diabetes for five years. He had been taking 10 units of protamine insulin daily until admission. For three years he had been subject to anginal attacks precipitated by exercise and relieved by nitroglycerin. There had been several episodes of ankle edema, orthopnea and nocturnal dyspnea. He had felt weak and tired since an attack of "virus pneumonia" five months before admission. He thought he had lost weight since that time but did not know how much. About four years before admission he had been jaundiced and felt weakness and malaise for three weeks. There had never been any previous episodes of abdominal symptoms.

The patient's father had died of diabetes, and a brother had the disease.

Physical examination showed a patient who appeared chronically ill and in moderate distress. The skin of the extremities and back had a dusky, cyanotic tinge. The tongue was thickly coated, and the breath fetid. The abdomen was distended, tympanic and nontender. There were shifting dullness and a fluid wave. No organs or masses were palpable. There was a soft, apical, systolic murmur. The lungs were clear. There was moderate pitting edema extending halfway up the leg, and slight pressural edema.

The temperature was 99°F, the pulse 80, and the respirations 20. The blood pressure was 130 systolic, 70 diastolic.

Examination of the blood disclosed a red-cell count of 4,400,000, with a hemoglobin of 16 gm, and a white-cell count of 8000, with 70 per cent neutrophils. The urine had a specific gravity of 1.012. The sediment was normal, and a test for bile was negative. There was a green sugar reaction. The stools were brown, formed and guaiac negative. The blood chemical values on admission were as follows: sugar 200 mg, nonprotein nitrogen 20 mg, and protein 5.8 gm per 100 cc, bilirubin 0.7 mg per 100 cc direct, 1.1 mg indirect, and carbon dioxide 31 milliequiv and chloride 88 milliequiv per liter. X-ray studies of the chest and abdomen showed both leaves of the diaphragm to be high, with haziness in the costophrenic sinuses. There was marked gaseous distention of the bowel, which could not be localized but was thought to affect both colon and small bowel. The peritoneal markings were not clear, indicating the presence of the fluid.

In the hospital the patient had a daily temperature between 100 and 102°F. A barium enema on the second hospital day showed delay of retrograde flow in the region of the splenic flexure, though barium passed into the dilated gas-filled and fluid-filled transverse colon. No definite lesion could be made out. The small intestine was also dilated. The urine reaction remained green on 10 units of regular insulin daily. The patient had a shaking chill on the third hospital day.

An exploratory laparotomy was performed on the sixth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR JAMES H TOWNSEND May we see the x-ray films?

These x-ray films are very impressive. We were not told about all this tubing, but there it is.

DR STANLEY M. WYMAN: We have only a few films from the original examination. Some of them were lost, apparently. The heart is definitely enlarged, chiefly toward the left, probably in the region of the left ventricle. The aorta is tortuous, and there is some calcification. There appears to be a small quantity of fluid in the left costophrenic angle and possibly on the right also. The lung fields reveal no definite intrinsic disease. The appearance of the chest is consistent with hypertensive arteriosclerotic heart disease, with probable fluid in both pleural spaces. This film of the abdomen with a Miller-Abbott tube in place was taken the day following the barium enema examination. The barium enema was done with the Miller-Abbott tube in place and quite a way down, as you see from the spot films. The patient was not prepared, and the examination, I gather from the record, was unsatisfactory. The fluoroscopist, in running the barium into the descending colon, arrived at the splenic flexure, where he had difficulty in forcing the barium farther. He took a number of spot films, which show barium passing into the distal transverse colon, where there is considerable fluid and retained material. The spot films of the area reveal no evidence of intrinsic filling defect, no definite kinks and no definite constriction by adhesions. I can say only from the films available that there was delay in the barium column at this point without a definite organic lesion. To go back to the plain film of the abdomen, there is a haziness that suggests fluid in the abdomen. This has to be taken with skepticism because this is a grid film.

DR TOWNSEND: From the data given I am sure that I shall be unable to make a precise diagnosis. However, there are certain possibilities that I can discuss.

To summarize the positive features, this fifty-five-year-old man, who was known to have had diabetes for five years, had an episode described as jaundice, which I think must always be taken with reservation. Four years before he had had what was called angina. For three years he had had a number of episodes of ankle edema, orthopnea and nocturnal dyspnea. Five months before admission he had what was called "virus pneumonia," and which easily could have been something else, perhaps pulmonary embolism or some other circulatory disturbance in the chest. He was brought to the hospital by an illness of three weeks' duration, characterized by abdominal cramps and swelling of the abdomen and of the ankles, and while in the hospital he had fever.

The physical examination showed a dusky color, apparently cyanosis, although there may have been something else about the color, a coated tongue, definite ascites and fever. From the laboratory evidence there was mild jaundice, elevated plasma

bilirubin, both direct and indirect, a slight reduction in serum protein, with a slight alkalosis and slight hypocalcemia, possibly associated with diet. I assume that since this man had cardiac failure he may well have been on a diet low in sodium chloride, which may have a bearing on the chloride of 88 milliequiv per liter. It is noteworthy that he did not have anemia and that the nonprotein nitrogen was normal. The blood sugar was high enough to prove the diabetes but not strikingly high. He did not have bile demonstrated in the urine. He apparently had normal amounts of bile in the stools. X-ray films suggest fluid in the pleural cavities and in the abdomen and gas-filled loops of bowel, which the x-ray people could not interpret entirely. They could not tell whether the whole intestine was dilated — paralytic ileus — or whether examination showed an obstructing lesion.

What are some of the possibilities? If we try to put them all together and put them on a cardiac basis, there seems little reason to doubt that this fifty-five-year-old man with diabetes had coronary-artery disease manifested by angina pectoris and symptoms of congestive failure. He also had a somewhat enlarged heart, and we wonder if the blood pressure had not been higher in the past than at present. We have no electrocardiographic evidence. I think we might say that he undoubtedly had coronary-artery disease and that he probably had some congestive failure. Could the cardiac condition have led to abdominal symptoms? Could he have had a mesenteric thrombosis or other thrombosis in the abdominal cavity? Yet if he had real mesenteric embolus, such as might come from thrombosis within the heart, one would hardly expect him to live three weeks. The episode would have been much more critical, and he would have died or been in serious trouble within a few hours as a rule. Is there anything about the cardiac condition that might lead to jaundice and ascites? Yes. Jaundice is not common in cardiac failure, although it may occur. Ascites may occur in most types of heart failure associated with right-sided heart failure, such as that seen with adhesive pericarditis or tricuspid lesions or with long-standing, definite, congestive failure, in which the nutmeg type of liver and, possibly, slight jaundice occur. However, this does not sound like that sort of history.

Are there any abdominal conditions that are part and parcel of the diabetes? There are at least three types of abdominal conditions that can produce abdominal symptoms and have diabetes as a feature. One is chronic pancreatitis, with enough destruction of islet tissue to produce diabetes, and I think it is possible that this patient could have had chronic recurrent pancreatitis. Jaundice and ascites can occur with it. This is a possibility, but I can see no way to prove it. The second abdominal condition associated with diabetes is a special form of liver cirrhosis, pigment cirrhosis. Hemochroma-

tos is associated with diabetes, usually from pancreatic fibrosis from pigment. This is seldom associated with jaundice, but I recall a case given to me a year or so ago in which four years before death the patient showed evidence of cirrhosis, including jaundice and ascites, and at that time on biopsy showed early Laennec's cirrhosis. Four years later, at the time of death from liver failure, there were extensive pigment deposits of the type called hemochromatosis. That is a possibility, but we have very little evidence, and I do not see how one can make the diagnosis.

Another possibility is cholesterol disease. We are not given the value of the blood cholesterol, but there is a condition of hypercholesterolemia which can be associated with deposits of cholesterol with fibrosis in the pancreas sufficient to cause diabetes. This also may be associated with enlarged liver and occasionally with jaundice. However, I doubt very much that it would lead to ascites, at least, I have never seen it. It can also be associated with coronary-artery disease and frequently terminates with coronary thrombosis.

What other possibilities should we consider? Ordinary liver cirrhosis, I think, is entirely possible. We are not given the usual battery of liver tests. We are told nothing about the prothrombin time, the cephalin flocculation test or the phosphatase level. We do know that he had ascites and jaundice, and that combination is always suggestive of Laennec's cirrhosis of the liver.

What about gallstones? There is a history of an attack of jaundice, without pain, four years ago. This time there were pain and jaundice. However, there seems to be very little to suggest that the patient was troubled with cholelithiasis, and it would be rather hard to explain the terminal picture on that basis.

What about the possibility of carcinoma of the pancreas? I think the possibility of neoplasm in the last few weeks of his life cannot be excluded. It could have been in the pancreas (it can be almost anywhere). I doubt that there is sufficient evidence to make a diagnosis without looking inside, which we are going to do vicariously in a minute.

One other possibility. Could he have had a spontaneous thrombosis of some radicle of the portal vein? Such things do occur. They are very difficult to diagnose in life and very apt to be associated with crampy, abdominal pain of indefinite character. They can be rapidly followed by the development of ascites and edema and large enough to result in a large area of gangrene of the bowel, but this man would not have lived three weeks if that had occurred. Of all possibilities, I think this is the least likely. If I were to list my diagnoses, I would say, of course, diabetes mellitus, coronary-artery disease and, I think, intra-abdominal thrombosis, probably in the portal system, possibly in some way related to cirrhosis of the liver.

DR WILLIAM DOCK I think these dusky legs make one think of hemochromatosis. That is an odd thing to have — cyanosis of the legs — without cyanosis of the lips, ears and fingers. With cyanosis of the back and legs it sounds as if he may have had an odd color, not merely diabetes with cyanosis, and it makes one suspicious. I think it is an important point. Patients with cirrhosis occasionally have bouts of fever and abdominal conditions unexplained by positive blood cultures or anything else. It may be that there was some intercurrent disease. However, I think this is a case in which terminal pyelophlebitis ought to be thought of. I should think he might have had carcinoma in the tail of the pancreas. I would be inclined to guess that he had bronze diabetes and got into new troubles superimposed on his cirrhosis, so that he came in on the Surgical rather than the Medical Service.

#### CLINICAL DIAGNOSES

Large bowel obstruction,<sup>2</sup> carcinoma  
Diabetes mellitus  
Angina pectoris

#### DR TOWNSEND'S DIAGNOSES

Diabetes mellitus  
Coronary-artery disease  
Cirrhosis of liver  
Intra-abdominal thrombosis

#### ANATOMICAL DIAGNOSES

*Hemochromatosis, liver, pancreas, skin and lymph nodes*  
*Hepatoma, with extension into hepatic and portal veins*  
Esophageal varices  
Ascites  
Splenomegaly  
Operations: exploratory laparotomy, bilateral femoral-vein ligation  
Thrombosis, left common femoral vein  
Hydrothorax  
Pulmonary congestion  
Chronic cholecystitis

#### PATHOLOGICAL DISCUSSION

DR JOHN B STANBURY The patient did come in on the Surgical Service. It was thought when he was first seen that there was distention of the small bowel, and enough possibility of small-bowel obstruction to justify surgical exploration. That was done. No obstruction was found, but a nodular liver was observed from which a biopsy was taken. It showed a marked grade of cirrhosis with a great deal of hemosiderin deposit, and a diagnosis of hemochromatosis was made. The patient was then transferred to the Medical Service, and the prognosis seemed so hopeless that they were not very

These x-ray films are very impressive. We were not told about all this tubing, but there it is.

DR STANLEY M. WYMAN: We have only a few films from the original examination. Some of them were lost, apparently. The heart is definitely enlarged, chiefly toward the left, probably in the region of the left ventricle. The aorta is tortuous, and there is some calcification. There appears to be a small quantity of fluid in the left costophrenic angle and possibly on the right also. The lung fields reveal no definite intrinsic disease. The appearance of the chest is consistent with hypertensive arteriosclerotic heart disease, with probable fluid in both pleural spaces. This film of the abdomen with a Miller-Abbott tube in place was taken the day following the barium enema examination. The barium enema was done with the Miller-Abbott tube in place and quite a way down, as you see from the spot films. The patient was not prepared, and the examination, I gather from the record, was unsatisfactory. The fluoroscopist, in running the barium into the descending colon, arrived at the splenic flexure, where he had difficulty in forcing the barium farther. He took a number of spot films, which show barium passing into the distal transverse colon, where there is considerable fluid and retained material. The spot films of the area reveal no evidence of intrinsic filling defect, no definite kinks and no definite constriction by adhesions. I can say only from the films available that there was delay in the barium column at this point without a definite organic lesion. To go back to the plain film of the abdomen, there is a haziness that suggests fluid in the abdomen. This has to be taken with skepticism because this is a grid film.

DR TOWNSEND: From the data given I am sure that I shall be unable to make a precise diagnosis. However, there are certain possibilities that I can discuss.

To summarize the positive features, this fifty-five-year-old man, who was known to have had diabetes for five years, had an episode described as jaundice, which I think must always be taken with reservation. Four years before he had had what was called angina. For three years he had had a number of episodes of ankle edema, orthopnea and nocturnal dyspnea. Five months before admission he had what was called "virus pneumonia," and which easily could have been something else, perhaps pulmonary embolism or some other circulatory disturbance in the chest. He was brought to the hospital by an illness of three weeks' duration, characterized by abdominal cramps and swelling of the abdomen and of the ankles, and while in the hospital he had fever.

The physical examination showed a dusky color, apparently cyanosis, although there may have been something else about the color, a coated tongue, definite ascites and fever. From the laboratory evidence there was mild jaundice, elevated plasma

bilirubin, both direct and indirect, a slight reduction in serum protein, with a slight alkalosis and slight hypocalcemia, possibly associated with diet. I assume that since this man had cardiac failure he may well have been on a diet low in sodium chloride, which may have a bearing on the chloride of 88 milliequiv per liter. It is noteworthy that he did not have anemia and that the nonprotein nitrogen was normal. The blood sugar was high enough to prove the diabetes but not strikingly high. He did not have bile demonstrated in the urine. He apparently had normal amounts of bile in the stools. X-ray films suggest fluid in the pleural cavities and in the abdomen and gas-filled loops of bowel, which the x-ray people could not interpret entirely. They could not tell whether the whole intestine was dilated — paralytic ileus — or whether examination showed an obstructing lesion.

What are some of the possibilities? If we try to put them all together and put them on a cardiac basis, there seems little reason to doubt that this fifty-five-year-old man with diabetes had coronary-artery disease manifested by angina pectoris and symptoms of congestive failure. He also had a somewhat enlarged heart, and we wonder if the blood pressure had not been higher in the past than at present. We have no electrocardiographic evidence. I think we might say that he undoubtedly had coronary-artery disease and that he probably had some congestive failure. Could the cardiac condition have led to abdominal symptoms? Could he have had a mesenteric thrombosis or other thrombosis in the abdominal cavity? Yet if he had real mesenteric embolus, such as might come from thrombosis within the heart, one would hardly expect him to live three weeks. The episode would have been much more critical, and he would have died or been in serious trouble within a few hours as a rule. Is there anything about the cardiac condition that might lead to jaundice and ascites? Yes. Jaundice is not common in cardiac failure, although it may occur. Ascites may occur in most types of heart failure associated with right-sided heart failure, such as that seen with adhesive pericarditis or tricuspid lesions or with long-standing, definite, congestive failure, in which the nutmeg type of liver and, possibly, slight jaundice occur. However, this does not sound like that sort of history.

Are there any abdominal conditions that are part and parcel of the diabetes? There are at least three types of abdominal conditions that can produce abdominal symptoms and have diabetes as a feature. One is chronic pancreatitis, with enough destruction of islet tissue to produce diabetes, and I think it is possible that this patient could have had chronic recurrent pancreatitis. Jaundice and ascites can occur with it. This is a possibility, but I can see no way to prove it. The second abdominal condition associated with diabetes is a special form of liver cirrhosis, pigment cirrhosis. Hemochroma-

Laboratory study revealed a serum van den Bergh of 1.8 mg per 100 cc direct and 2.0 mg per 100 cc indirect and an amylase of 116 units per 100 cc. The hemoglobin was 11 gm, and the white-cell count 6000. The specific gravity of the urine was 1.003, but examination was otherwise negative.

In the hospital the patient had another acute attack of pain, from which she was allowed to recover before operation. In the meantime she was given penicillin, streptomycin and three blood transfusions. On the twelfth hospital day a cholecystectomy and choledochostomy were done. One large and several small stones were found in the common duct, which was noted to be very large but soft. She convalesced well and was discharged on the tenth postoperative day. A cholangiogram done two days before discharge showed good filling of the biliary radicles, both intrahepatic and extrahepatic. There was some dilatation of the whole system, but the dye passed readily into the duodenum.

*Final admission* (two months later) In the interval the patient had been followed in the clinic and was very well when last seen, approximately six weeks before the present admission. She had continued to be up and about feeling well until two days before admission, when she noted the onset of anorexia and abdominal discomfort. On the following day she went to bed and had nausea and vomiting of blood of an unknown amount. She was also said to have passed blood by rectum. On the morning of the day of admission she was found unresponsive. It was also noted that the skin was yellowish. She was admitted in a state of coma.

Physical examination revealed a comatose, emaciated woman breathing heavily. The skin and conjunctivas showed jaundice. The lungs were clear. Abdominal and neurologic examinations were essentially negative. Rectal examination was negative.

The temperature was 98.6°F, the pulse 100, and the respirations 20. The blood pressure was 130 systolic, 90 diastolic.

Laboratory examination revealed a serum van den Bergh of 8.5 mg per 100 cc direct and over 12.5 mg per 100 cc indirect and a nonprotein nitrogen of 42 mg per 100 cc. The carbon dioxide was 22 milliequiv per liter, and the sugar 76 mg per 100 cc. Determination of the prothrombin time was attempted, but the blood did not clot even after 120 seconds with a control of 16 seconds. The hemoglobin was 15 gm, and the white-cell count 9000, with 81 per cent neutrophils. The urine

showed a ++ test for bile. A stool was guaiac negative.

On the following morning the patient's respirations were more rapid, and the jaundice deeper. Later that day respirations ceased, and she died.

#### DIFFERENTIAL DIAGNOSIS

DR GRANTLEY W. TAYLOR This is an extraordinary case. There are several points of considerable interest. First of all, this woman had a carcinoma of the colon at the age of fifty-five, which was cured apparently. At the age of sixty-seven she entered again with a carcinoma of the esophagus, which was an epidermoid, Grade III. This must represent one of the rare, very early cures of carcinoma of the esophagus because seven years later, when the gall bladder was operated on, I think it would have been remarked if she had shown any evidence of intra-abdominal extension or recurrence of carcinoma. She lived long enough to justify the original diagnosis of gall-bladder disease because when she came back on the eighth admission she had gallstones.

When the patient came in on the eighth admission she was a sick woman with frequent attacks of sharp pain, nausea, vomiting, gaseous eructations and questionable icterus, and she was in poor shape. The only extraordinary thing in this admission is the amylase of 116 units, which, if true, is certainly extreme. It makes one wonder if she had pancreatitis. Pancreatitis is certainly an overwhelming disease. She had an attack of pain but was not in any acute discomfort, and I am inclined to think that the amylase determination was an error. She was treated with penicillin, streptomycin and blood transfusions—again, a method of therapy consistent with the assumption that she had pancreatitis or something of that sort. Nothing was done until the twelfth day, when gallstones were removed and the common duct drained. A cholangiogram was done before discharge, which means that she had a T-tube in place and the idea was to carry out a protracted drainage of the biliary tree. That is what I get out of it. At readmission nothing is said about a biliary sinus or a biliary catheter. However, she was followed in the Out-Patient Department and did very well until just before the final admission, when she had an overwhelming onset of the final illness—an episode of anorexia, abdominal discomfort, nausea, vomiting and bleeding by rectum—and lapsed within two days into a state of

much interested in doing any great battery of liver-function tests. The bromsulfalein test showed 40 per cent retention of the dye, and the thymol turbidity was 7 units.

DR TRACY B MALLORY The patient died in two weeks. There was an episode suggesting pulmonary embolism following which the leg veins were ligated on both sides. From that time on there was constant seepage of fluid through the wounds where the veins had been ligated that could not be stopped. The peritoneal fluid evacuated at operation reaccumulated rapidly.

At autopsy we found that the liver weighed 3400 gm and was very grossly nodular, with two types of nodules, quite sharply distinct in color. In cutting across the liver we found in the central portion a large tumor similar in appearance and color to one of the types of nodules. Also, many thrombi were found in both the hepatic and portal veins. So the diagnosis of primary hepatoma with invasion of the venous system of the liver was made. There was also a thrombotic occlusion of the portal vein behind the tumor thrombus. There was moderate involvement of the adrenal glands and pancreas, and the lymph nodes in the porta hepatis were deeply pigmented.

DR TOWNSEND Was any reason found for the rather sudden decline of the patient three weeks before entry?

DR MALLORY I imagine that represents the rapid progress of the hepatic carcinoma, which spread very quickly throughout the venous system of the liver.

DR TOWNSEND Do you often find hepatic carcinoma developing on the basis of hemochromatosis?

DR MALLORY I have the impression that I have seen it disproportionately often in hemochromatosis. I have seen figures saying that that is not so. Considering the rarity of hemochromatosis, I think a surprising number of patients die with hepatoma.

DR JOHN B QUINBY What did the heart show?

DR MALLORY Mild atherosclerosis of the coronary arteries without narrowing and no infarction. The kidneys showed nothing remarkable.

### CASE 34522\*

#### PRESENTATION OF CASE

*First admission* A fifty-one-year-old unmarried woman was admitted to the hospital because of

severe epigastric pain. A diagnosis of gall-bladder disease was made. The symptoms subsided almost completely, and she was discharged on the fifth hospital day.

*Fourth admission* (four years later) In the interval the patient had two admissions for recurrent bouts of epigastric pain. During the last she underwent an exploratory laparotomy and appendectomy. The abdominal organs, including the gall bladder, were grossly normal. During this admission the patient was found to have an adenocarcinoma of the sigmoid colon, and a Mikulicz operation was subsequently done. She was discharged on the sixty-second hospital day.

*Seventh admission* (approximately twelve years later) In the interval the patient had been admitted on two separate occasions for a ventral hernia and for closure of the colostomy wound, the last admission being ten years before this one. At this time she was admitted because of increasing difficulty in swallowing and some weight loss. A roentgenogram showed findings consistent with carcinoma of the lower third of the esophagus. A biopsy showed epidermoid carcinoma, grade III. An esophagectomy and esophagostomy were done, and the patient discharged on the forty-third hospital day.

*Eighth admission* (seven years later) In the interval the patient had been seen more or less regularly in the Tumor Clinic, and no evidence of recurrence of either the esophageal or the sigmoid cancer noted. Approximately one month before admission she began to have frequent attacks of sharp, stabbing pain in the right upper quadrant. This pain was severe and accompanied by nausea, vomiting and gaseous eructations. The pain radiated to the back but not into the shoulder. She denied any change in the stools or urine but admitted to being jaundiced with several of the attacks. The present episode had begun four days before admission.

Physical examination revealed a poorly nourished woman in no acute discomfort. The scleras and skin were questionably icteric. The lungs were clear. The abdomen was flat, and numerous dilated veins were seen coursing under the skin. There appeared to be a considerable amount of voluntary spasm. The right upper quadrant was tender to deep palpation, but neither liver nor gall bladder could be felt. The spleen was not palpable.

\*Presented at a meeting of the New England Cancer Society held at the Massachusetts General Hospital.

Laboratory study revealed a serum van den Bergh of 1.8 mg per 100 cc direct and 2.0 mg per 100 cc indirect and an amylase of 116 units per 100 cc. The hemoglobin was 11 gm, and the white-cell count 6000. The specific gravity of the urine was 1.003, but examination was otherwise negative.

In the hospital the patient had another acute attack of pain, from which she was allowed to recover before operation. In the meantime she was given penicillin, streptomycin and three blood transfusions. On the twelfth hospital day a cholecystectomy and choledochostomy were done. One large and several small stones were found in the common duct, which was noted to be very large but soft. She convalesced well and was discharged on the tenth postoperative day. A cholangiogram done two days before discharge showed good filling of the biliary radicles, both intrahepatic and extrahepatic. There was some dilatation of the whole system, but the dye passed readily into the duodenum.

*Final admission* (two months later). In the interval the patient had been followed in the clinic and was very well when last seen, approximately six weeks before the present admission. On the following day she went to bed and had nausea and vomiting of blood of an unknown amount. She was also said to have passed blood by rectum. On the morning of the day of admission she was found unresponsive. It was also noted that the skin was yellowish. She was admitted in a state of coma.

Physical examination revealed a comatose, emaciated woman breathing heavily. The skin and conjunctivas showed jaundice. The lungs were clear. Abdominal and neurologic examinations were essentially negative. Rectal examination was negative.

The temperature was 98.6°F, the pulse 100, and the respirations 20. The blood pressure was 130 systolic, 90 diastolic.

Laboratory examination revealed a serum van den Bergh of 8.5 mg per 100 cc direct and over 12.5 mg per 100 cc indirect and a nonprotein nitrogen of 42 mg per 100 cc. The carbon dioxide was 22 milliequiv per liter, and the sugar 76 mg per 100 cc. Determination of the prothrombin time was attempted, but the blood did not clot even after 120 seconds with a control of 16 seconds. The hemoglobin was 15 gm, and the white-cell count 9000, with 81 per cent neutrophils. The urine

showed a ++ test for bile. A stool was guaiac negative.

On the following morning the patient's respirations were more rapid, and the jaundice deeper. Later that day respirations ceased, and she died.

#### DIFFERENTIAL DIAGNOSIS

DR GRANTLEY W TAYLOR. This is an extraordinary case. There are several points of considerable interest. First of all, this woman had a carcinoma of the colon at the age of fifty-five, which was cured apparently. At the age of sixty-seven she entered again with a carcinoma of the esophagus, which was an epidermoid Grade III. This must represent one of the rare, very early cures of carcinoma of the esophagus because seven years later, when the gall bladder was operated on, I think it would have been remarked if she had shown any evidence of intra-abdominal extension or recurrence of carcinoma. She lived long enough to justify the original diagnosis of gall-bladder disease because when she came back on the eighth admission she had gallstones.

When the patient came in on the eighth admission she was a sick woman with frequent attacks of sharp pain, nausea, vomiting, gaseous eructations and questionable icterus, and she was in poor shape. The only extraordinary thing in this admission is the amylase of 116 units, which if true, is certainly extreme. It makes one wonder if she had pancreatitis. Pancreatitis is certainly an overwhelming disease. She had an attack of pain but was not in any acute discomfort, and I am inclined to think that the amylase determination was an error. She was treated with penicillin, streptomycin and blood transfusions — again a method of therapy consistent with the assumption that she had pancreatitis or something of that sort. Nothing was done until the twelfth day, when gallstones were removed and the common duct drained. A cholangiogram was done before discharge, which means that she had a T-tube in place and the idea was to carry out a protracted drainage of the biliary tree. That is what I get out of it. At readmission nothing is said about a biliary sinus or a biliary catheter. However, she was followed in the Out-Patient Department and did very well until just before the final admission, when she had an overwhelming onset of the final illness — an episode of anorexia, abdominal discomfort, nausea, vomiting and bleeding by rectum — and lapsed within two days into a state of

coma On examination she was breathing heavily and was jaundiced Obviously she had severe derangement of the bleeding tendency when she came back because the blood taken for prothrombin time did not clot, even after two hours The blood hemoglobin was 15 gm, perhaps owing to hemoconcentration The white-cell count was normal, the urine showed bile, and the stool was guaiac negative — a contradiction to the history of hematemesis and melena

As I studied this case the question was obviously whether or not this was a complication of the former carcinoma in the form of hepatic metastases It seems extremely unlikely that two months after cholecystectomy, at which time presumably the liver was not manifesting hepatic metastases, metastatic disease involving the liver from either of the previous carcinomas would occur Of course the interesting thing is how rarely we see jaundice in cases of metastases involving the liver Then the question is whether she was suffering from a complication of the cholecystectomy We have been known to injure the common duct, even in this hospital, so that she could very well have had such a complication Against that is the fact that following cholecystectomy she did well for two months The terminal illness was abrupt — two days — and of severe onset Were one large and several small stones removed and one that descended to cause another acute episode of obstructive mechanical jaundice left? I think that is rather unlikely The lapse of the patient into coma, with a protracted prothrombin time such as that described here, sounds to me as if she had a profound visceral derangement of the liver, and that the terminal episode was one of liver failure — due to what, I cannot tell you It is consistent with severe hepatitis or acute yellow atrophy or something of that sort

What else could she have had? A hemorrhagic pancreatitis? At the final episode she complained of anorexia and of abdominal discomfort but nothing suggestive of the overwhelming onset of abdominal distress of pancreatic apoplexy That is as far as I can go

DR GEORGE LEVENE Is the pain radiating back into the shoulder suggestive of pancreatitis?

DR TAYLOR On the eighth admission she probably had something for which she was kept in the hospital for twelve days and given penicillin, streptomycin and transfusions We have very few data

given here, but everything was normal except for the elevated amylase It must have been thought that she had a pancreatitis secondary to biliary-tract disease because biliary drainage was instituted, a T-tube put in place and a cholangiogram taken before she went home Nothing is said about the state of the pancreas or the abdominal findings

DR LOUIS P HASTINGS Dr Taylor, did she have plasma transfusions a few months previously? What is the possibility of homologous serum hepatitis here?

DR TAYLOR I think it is possible We know that some of these patients have tremendously severe jaundice supervening on that basis We certainly do not expect it with transfusion of whole blood as commonly as we do with plasma

#### CLINICAL DIAGNOSIS

Homologous serum hepatitis

#### DR TAYLOR'S DIAGNOSIS

Hepatitis, with liver failure

#### ANATOMICAL DIAGNOSIS

*Homologous serum hepatitis*

#### PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN At autopsy this patient had a very small liver, weighing 700 gm, it was soft, flabby, and brownish red, more so on the right side, with small, yellowish to grayish-white areas here and there These grayish-white areas represented portal areas, and the reddish-brown areas represented the central parts of the lobule In the central parts of the lobule the liver cells were wiped out completely and replaced by blood This case represents an acute hepatitis of a fulminant variety and quite consistent with homologous serum jaundice The patient had received three transfusions, and I have asked Dr Soutter, who is in charge of the Blood Bank, to comment on the possible causes of the hepatitis

DR LAMAR SOUTTER This case was of great interest to us because of our desire to avoid this complication The possible source of homologous serum jaundice could have been from a needle or from a transfusion For the past half year, at least, all hypodermic and intravenous needles in the hospital have been autoclaved so that the possibility of receiving hepatitis from another patient through the means of the needle is almost nonexistent In

this case the other possible source is the transfusions. Out of 50,000 whole-blood transfusions from our Blood Bank this is the first case of homologous jaundice. Undoubtedly, there may be others in which the diagnosis was not made or the patient had a light case of jaundice not attributed to this source. It is possible for a person to have hepatitis or jaundice and not know about it—or not remember about it. We do not have any idea how long one is capable of carrying the virus before transmitting it to someone else. We do know that the incidence of homologous serum jaundice following whole-blood transfusion is infrequent as compared with that after dry plasma.

We investigated the donors of the three transfusions in this case. The first donor was a Negro boy, a professional donor of this hospital. He had been used before, and I am sure, after questioning him carefully, that he had no knowledge of ever having had any disease similar to jaundice or hepatitis. The second donor was a Red Cross volunteer, whose blood was sent to us by the Red Cross. I talked to him and found that there was no history of hepatitis or jaundice. The third blood came from an institution that establishes a credit in this hospital from which it can draw blood when needed. Unfortunately, although we believed that that institution had standards comparable to our own and observed the state and federal regulations regarding histories and physical examinations for donors, we found that it had collected blood at a prison but had neglected these matters. We assume that the blood that infected this patient came from that source, but of course there is no proof. The moral is obvious—a careful screening of donors must take place to keep down the incidence of the disease. I do not mean screening by the mere process of a

technician asking the donor if he has had jaundice. But if a doctor will ask the donor if he has had “yellow jaundice” of the skin or scleras and will go into the symptoms of hepatitis, we may cut down on this unfortunate complication.

DR RICHARD B. CATTELL: Dr. Castleman, have you ever observed this same picture in the liver in deaths following extensive disease with long common-duct obstruction due to stone?

DR CASTLEMAN: No, we never see it with stones. The liver, if involved, would be large, not small.

DR CATTELL: I mean following operation for common-duct stones.

DR CASTLEMAN: Not so rapidly as this. The patient died within three days of the onset of symptoms. It was a fulminating form of liver disease. I do not believe I have seen obstruction that fast. Have you?

DR CATTELL: No.

DR JOHN FALLON: What did you find in the pancreas?

DR CASTLEMAN: Nothing. The common duct was not dilated, and there were no residual stones.

DR TAYLOR: The tube had been taken out after the final cholecystogram?

DR CASTLEMAN: Yes. A note was made to that effect in the Out-Patient Department record.

DR TAYLOR: I did not make out why, on the eighth admission, the patient was kept for twelve days on penicillin, streptomycin and transfusions—in preparation for a gall-bladder operation.

DR CASTLEMAN: It was thought that she had acute cholecystitis. She was very sick before operation.

DR SOUTTER: The cardiologists spent five days getting her ready for operation.

## IN UNION STRENGTH

THE proposal of the Blue Cross and Blue Shield plans to form a joint national association for more effective interstate operation has met with vigorous though not unexpected opposition. The proposed organization, under the name of Blue Cross-Blue Shield Association, Inc., was to have been a non-profit membership corporation for the purpose of providing mechanisms for facilitating plan enrollment activities, collecting and interpreting experience data for all plans, basic underwriting and actuarial service for all plans, and the organization of Blue Cross-Blue Shield Health Service, Inc., as a stock insurance company. The object of the Health Service was to furnish coverage to employees of national firms where approved plans do not exist,

and excess coverage where necessary, a central agency through which enrollment, billing and collection could be handled for nationally enrolled groups, uniform rates and benefits for all employees of nationally enrolled groups regardless of place of residence, and uniform regulations regarding enrollment, membership and administration of benefits. These provisions were to provide its sole purpose for existence.

Opposition to it was based on the fear that in union there is too much strength, that centralization of organization entails centralization of authority, that this country's cherished heritage of free enterprise would be placed in jeopardy, and that an organization for the control of medical practice would be ready at hand for the Government to take over at will.

Here there was present the usual basis of controversy — not between clear right and clear wrong — but between two arguments, each of which contains or seems to contain points in its favor.

Despite the dangers that were so clearly set forth by the opponents of the proposed association, it had to be borne in mind by the medical profession that the probable alternative to the acceptance of some larger and well organized voluntary prepayment plan for medical service would be a determined attempt at Government control as outlined in Mr. Ewing's recently publicized ten-year program. It seemed also apparent to many observers of modern political trends that the motto *E pluribus unum*, adopted at one time with a reasonable show of enthusiasm, may still have its virtue. The remark attributed to Benjamin Franklin after the signing of the Declaration of Independence that the signers would do well to hang together unless they wanted to hang separately, indicates only that the advantages of united effort may sometimes outweigh its disadvantages.

The Blue Cross and Blue Shield Commissions were directed by the Los Angeles Conference of Blue Cross and Blue Shield plans in April, 1948, to revise the original proposals for a national association and submit them to the conference of plans to be held in October at French Lick Springs. This was done, the Blue Shield plans voted to submit the whole matter to the House of Delegates at its

meeting this month at St. Louis, and the Blue Cross voted to adopt the proposals but to defer action until after the same meeting.

The House of Delegates, giving as a main reason for its decision the possibility of Department of Justice action against a national company, voted to disapprove the association, favoring instead a national enrollment agency to co-operate in coordinating all prepaid health insurance plans. Such an agency would not be limited to sponsoring Blue Cross and Blue Shield plans alone.

The clear duty of the physicians of the country is now to support the actions and the decisions of their representative body, disregarding any differences of opinion that may previously have existed. The problems that lie ahead can be satisfactorily solved only by complete co-operation, and by recognition of the authority with which the House of Delegates of necessity speaks.

---

### "FORSAKE NOT THYSELF"

THREE moral obligations implicit in the ministry of the physician are the subject of Dean Willard L. Sperry's talk before the staff of the Massachusetts General Hospital, published elsewhere in this issue of the *Journal*, they concern the practice of medicine, but they present also logical points of contact with the profession of ministering to the mind and to the soul. They are to tell the truth, but so kindly that silence may sometimes take the place of words, to maintain at all times a sense of the sacredness of life, and to consider the individual at the expense of that abstraction known as mass man.

Judgment, as Hippocrates said, is difficult, and often the definition of a problem may be more stubborn than its answer. Moral judgments in particular may be relative, and the right of yesterday may be the wrong of today. Ethics can quickly change for the worse as well as for the better, and the change can be easily accepted, as was shockingly demonstrated during the years of Hitler's leadership in Germany. The principle of conscience, however, according to Dean Sperry's thesis "has an absolute warrant and cannot change."

Often the moral choice that confronts the physician is not between black and white, where the just course is plainly marked, but between two shades of gray. Having chosen what seems to be the lighter shade he must go ahead "on the assumption that it becomes a clear white." Tragedy is not a matter of a conflict between good and evil, but "a matter of a collision of two loyalties, each of which is wholly good on its own ground." This conflict has been tersely phrased by Richard Lovelace, whom Dean Sperry quotes:

"I could not love thee, dear, so much  
Loved I not honour more."

The ethics of truth-telling must be tempered with discrimination. Falsehood is not to be condoned, but as a matter of mercy and of what might be called the greater honesty, the absolute truth or what it seems to be, may sometimes need to be withheld. Time, too, may suddenly so change the apparent facts that what was held to be the truth becomes an error.

The problem of euthanasia does not immediately or openly concern the physician, but it involves a principle on which he must take his stand. This must be settled for the physician as for the minister on the basis of a profound reverence for life. A deviation on the part of medicine from its basic principle of saving life must constitute a crack in its armor. "If we forfeit that reverence we have slipped our moral moorings—it is not our business to take life, only to try to save it."

In the face of mass evaluations of strong nationalistic and group trends, of the principle of the greatest good to the greatest number, the physician in partnership with the minister must continue to have faith in the value of the individual.

---

### THE MEDICOLEGAL DEATH

Few physicians, in all probability, are entirely clear in their minds as to the exact nature of their obligations to the state in the matter of death reports. Their medicolegal obligations, at least so far as these relations in the Commonwealth of Massachusetts are concerned, are admirably presented in the article by Ford published elsewhere in this issue of the *Journal*.

Certain categories of death, as set forth, must come under the jurisdiction of the medical examiner. These and certain others—hospital deaths within twenty-four hours of admission, hospital deaths when the decedent was unconscious on admission and remained so, any death pronounced by a physician other than the attending physician and any death when the patient was not attended by a physician within two weeks—must be reported to the medical examiner for his decision as to jurisdiction.

Deaths so reported in which the medical examiner declines authority may be certified by the attending physician if he is available and attended the decedent at least twice, one of which visits was within two weeks of death. Otherwise the board-of-health physician may make the certification.

The interest of the public is in discovering and solving crime and in protecting the public health where it may be endangered by virulent communicable disease, by industrial hazards or otherwise.

The friction that sometimes exists in metropolitan areas between the resident staffs of hospitals and the medical examiner's office over the performance of autopsies could be largely eliminated by a proper understanding by the former of the duties of the latter. These difficulties could largely be eliminated, as Dr. Ford says, "if each hospital were to designate a single physician with the experience and authority necessary to ensure complete and accurate reporting of medicolegal deaths and to facilitate the prompt viewing of bodies at the hospital." If this were done, more cases would be available for hospital autopsy.

---

## THE WASHINGTONIAN HOSPITAL

IN SPITE of many difficulties, the Washingtonian Hospital is carrying on. As the oldest hospital of its kind in the United States, it is continuing to make its contribution to the treatment of alcoholism. Because of its obscure location and quiet work, few people realize that behind its ancient façade patients with acute and chronic alcoholism are continuously being treated by psychotherapy and reflex conditioning. Alumni of the hospital

have formed a "conditioning club" that meets semimonthly for group therapy with the medical director.

Last year 941 inpatients and 106 outpatients were given treatment. The average daily census is about 25. The bed capacity is 35.

Since its reorganization some ten years ago, it has continued its relation with the Community Fund. It maintains friendly relations with the Alcoholics Anonymous groups, but its main support comes from patients referred for treatment by private practitioners.

The Washingtonian Hospital, an institutional member of the American Hospital Association, is unique in offering the following services: treatment of acute alcoholic psychoses, acute intoxication without psychoses, cirrhosis of the liver, alcoholic neuritis, vitamin deficiency and malnutrition. It also institutes withdrawal procedures for certain alcohol and drug addicts. Other functions emphasized are efforts to rehabilitate alcohol addicts by psychotherapy, including some patients who require part-time hospitalization with working arrangements and social case work. Public education through addresses given to professional and lay groups is also emphasized. Consultative advice to social agencies and community leaders interested in problem drinkers is given.

In spite of the rising costs of medical care, the hospital is carrying on, mainly because a real need for it exists and because physicians practicing in Massachusetts know of its long service record and the accomplishments it has demonstrated in this uphill work.

---

## MEDICOLEGAL ABSTRACT

**Liability for Malpractice — Administration of narcotics.** A recent Massachusetts case involved questions of such general interest in connection with the liability of physicians for their administration of narcotics that a brief was filed in the case in behalf of the Massachusetts Medical Society.

The testimony in the case was wholly contradictory on the essential questions of how much morphine was given and under what circumstances it was given. The evidence in its aspect most favorable to the patient, who sued the doctor, was that on December 25, 1939, she was suffering from

nausea but without pain, that the defendant, without any complaint of pain by her and without any physical examination or questions regarding medical history, gave her a hypodermic injection of morphine, which was repeated twice that day, that early in 1940 the defendant gave her another injection in similar circumstances, that in 1941 the defendant gave her occasional injections until by July she was receiving about two injections a week, that by the end of August he was giving her an injection every day, in September twice a day, and in October three times or more a day until the patient's husband ordered the defendant from the house and threatened to "clean him up", that thereafter the patient became "jumpy and nervous", and that two days later, after telephoning about every doctor in the town for morphine, the patient experienced a complete black-out and was taken to a hospital suffering from morphine addiction and described as "one-quarter of the way along to confirmed addiction." The patient testified in effect that she had never stated that she had pain until after the defendant had ceased giving her the injections. There was medical testimony that it was not proper medical practice to administer morphine to a patient who complained of nausea but not of pain, or over a period in which there was no pain involved, or to continue giving morphine in the absence of a diagnosis of a condition that could not be cured.

There was evidence that another physician had given the patient codeine from 1939 on and during the period in which the defendant was treating her. There was also evidence that the patient had taken quantities of phenobarbital at some time, although it was not shown that she had taken phenobarbital during the period when she was receiving frequent injections of morphine from the defendant. Therefore, the question was presented whether the patient's condition when she was taken to the hospital was caused by morphine administered by the defendant or by other drugs. The court held that there was ample evidence, presumably the diagnosis of her condition as morphine addiction, to indicate that her condition was proximately caused by morphine administered by the defendant.

The court does not explain in what sense the injections given by the defendant caused the patient's condition. The court presumably meant that the jury could have believed that the injections given by the defendant were sufficient by themselves to account for the patient's condition or that the defendant's treatments would have caused some kind of breakdown by themselves although the patient's condition may have been aggravated by the codeine and phenobarbital. There is a sense in which a doctor may be said to have caused an addiction if his patient merely learns to like the effect of a drug from his injections, and the patient, afterward satisfying her taste from other sources, be-

comes an addict. The court apparently did not regard the case before it as such a case and it did not decide what rule should be applied in such a case.

The defendant argued that the plaintiff sought the morphine she got from him, knowing the risks involved and voluntarily assuming them. The court did not deny that she would be barred from recovery if such testimony were true but rejected this argument for the reason that on the evidence the jury could have found that she did not know or assume the risks. The plaintiff herself testified that if not at first, at least eventually, she sought the injections she received from the defendant. She testified that by about the last of July, 1944, she was "beginning to get a little sneaky—starting to lie" and did not always tell the defendant the truth about her condition. She testified that she did not know what the defendant was giving her, although in July she had a "suspicion," and she knew that it was something that was relieving her and making her feel "pretty high." The court concluded

From this, together with other evidence that need not be stated, the jury could have found that she knew she was getting morphine, but they were not obliged so to find. Much less were they obliged to find that she knew at what point addiction would begin, or that at any time before addiction became a fact she had ceased to rely upon the superior knowledge of the defendant as to the amount of the drug that could safely be taken over a given period of time. There was medical evidence that a person could become addicted "without knowing it."

The court plainly implied that after addiction has become a fact the patient might not be wholly responsible for her actions in attempting to get morphine injections and might not be barred from recovery on the ground that she assumed the risks. It is obvious in this case that when the patient started lying to the defendant to obtain morphine injections she had ceased to rely on the superior knowledge of the defendant and begun to assume the risks herself. The court must have thought that the jury could find that this was after the addiction was a fact. The time of addiction, therefore, becomes an important issue in cases such as this.

It was argued in the case that the patient by "lying" to obtain morphine injections was guilty of a criminal offense, which should prevent her from holding the doctor liable. However, the court held that the statute, which applied only to lying "for the purpose of procuring a prescription for, or the delivery of, a narcotic drug," was not applicable to a case of misrepresentation for the purpose of obtaining an injection personally administered by the doctor, such an injection not being a "delivery" within the meaning of the statute.

The court held that on this evidence, the jury could render a verdict for the plaintiff, even if they need not have done so. Reassuring the medical profession the court said

This decision rests upon evidence of improper and unprofessional conduct on the part of the defendant leading to addiction in the plaintiff. Nothing contained herein need cause anxiety to an honest physician who administers narcotics to a patient in accordance with the prevailing standards of medical practice.

This reassurance must be read in the light of the practical difficulties of proof that may be involved. In any case an honest doctor takes the risk that his testimony may not be believed. For example, in the case before the court, if the defendant's records and testimony had been believed, he would have appeared to be an honest physician administering narcotics to a patient in accordance with the prevailing standards of medical practice. The jury, however, apparently believed the patient's testimony, and this required the court to view the defendant's conduct in a different light (*King v Solomon*, 1948 Mass Adv Sh 1005).

## CORRESPONDENCE

### UNIVERSITY OF ROCHESTER TRAINING PROGRAM IN PSYCHOTHERAPY

To the Editor: I have read with great interest the article entitled "Medical Schools and the Quality of Medical Care," by Dr. F. Richard Weirnerman, which appeared in the November 25 issue of the *Journal*. I think that you are doing the profession a great service by publishing articles (and editorials!) on the subject of modern medical training and its socio-economic aspects. This is a timely reminder for those of us who, as students, find ourselves confronted with a maze of material in clinical medicine and who may therefore lose sight of the other implications of disease.

Nevertheless, for the sake of the record, I should like to point out that at the University of Rochester, under the expert guidance of Dr. John Romano, a well integrated program of training in psychotherapy has been initiated. This program began two years ago and now applies to students in all years. A new building has recently been erected for the hospitalization of patients with mental illness, and students in their third and fourth years are receiving intensive training in this new clinic. The course given here not only includes the study of basic psychiatry but also considers the ancillary disciplines of sociology and economics, as presented in lectures by persons who head the social service at the Strong Memorial Hospital.

Most of the students realize the great importance of this aspect of medical training — and not only of medical training but of medical living and thinking, if I may call it that.

Articles like Dr. Weirnerman's are therefore highly welcome and I hope that others on this vital topic will be forthcoming in your splendid *Journal*.

ERNEST J. LEVINER  
Third-Year Student

University of Rochester School of Medicine

## BOOK REVIEWS

*Unipolar Lead Electrocardiography. Including standard leads, unipolar extremity leads and multiple unipolar precordial leads.* By Emanuel Goldberger, B.S., M.D. 8°, cloth, 182 pp., with 88 illustrations. Philadelphia: Lea and Febiger, 1947. \$4.00.

Dr. Goldberger's book is really the first devoted almost exclusively to the subject of unipolar leads. Although these leads were studied and described by Wilson many years ago, they have come into general use only recently. The literature on this subject is growing rapidly but there has been a real need for a textbook to explain the theory and define the uses

and limitations of unipolar leads. Dr. Goldberger's book fills this requirement in part.

The presentation of material is an orderly one, beginning with an explanation of underlying theory, continuing with detailed instructions for taking leads and ending with a discussion of their clinical application.

Reasonable objections can be raised to the rather dogmatic way in which the subject matter is presented. Nevertheless, the book serves a very useful function in placing proper emphasis upon the origin of extremity lead patterns from basic patterns in the heart itself. Dr. Goldberger's approach also serves to emphasize heart position in relation to the recording electrodes. This represents another step away from purely empirical interpretation even though one does not agree with every statement the author makes. This monograph is not intended as a complete textbook and therefore detailed evaluations of unipolar leads cannot be expected. This book is recommended to all who are interested in electrocardiography.

*The Epithelia of Woman's Reproductive Organs. A correlative study of cyclic changes.* By George N. Papanicolaou, M.D., Ph.D., Herbert F. Traut, M.D., and Andrew A. Marchetti, M.D. 4°, cloth, 53 pp., with 22 plates. New York: The Commonwealth Fund, 1948. \$10.00.

This monograph records a decade of painstaking correlative research at Cornell University Medical College, sponsored by the Commonwealth Fund and conducted by three professorial experts in the fields of microscopical anatomy, biology, physiology and gynecology. The epithelial cytology of the normal human female reproductive tract is extensively examined, and its changes intensively studied in relation to the menstrual cycle. The results are embodied not only in the text but also in a large, colored folding chart, and are amplified and presented in twenty-three full-page plates of drawings and colored photomicrographs. There is a foreword by Dr. Joseph C. Hinsey, dean and professor of anatomy at Cornell University Medical College. In their introduction the authors review the literature of the subject especially the epochal work of Rock and Hertig in the classification of the menstrual cycle, which is recorded in a bibliography of ninety titles.

This volume represents a monumental piece of research of permanent value, for it goes far to clarify and complete knowledge in the field and subject with which it deals, and was made possible by the intelligently co-ordinated and directed skills of investigators, technicians, and clinicians working harmoniously in a common enterprise toward a common objective.

## NOTICES

### POSITIONS FOR CIVILIAN DOCTORS IN PANAMA

Permanent appointments, in the Civil Service, for physicians now exist in the Panama Canal Medical Service. Salaries range from \$5599 to \$7794, with free transportation to the Canal Zone provided for physicians, their families and household goods. Return transportation is furnished upon completion of a minimum of one year's service. In addition, doctors who receive appointments get two months' paid vacation (including time lost by illness) and reduced fares on Panama Canal passenger vessels.

Requirements for position paying \$5599 to \$6540 are graduation from an approved medical school, license to practice medicine in a state, ability to pass a standard physical examination and completion of one year of internship in a hospital approved by the American Medical Association.

Requirements for positions paying \$6540 to \$7794 are the same except that a minimum of three years of post-internship experience is required.

Physicians who are interested in a position as medical officer in the Panama Canal Zone should communicate with Chief of Office, The Panama Canal, Washington, D.C. Applications may also be submitted to the United States Civil Service Commission, Washington, D.C.

(Notices concluded on page vi)

## ANNOUNCEMENTS

Dr Samuel R Manelis announces the opening of his office for the practice of orthopedic surgery and fractures at 321 North Main Street, Fall River

Dr Eugene F McAuliffe announces the opening of offices at 1180 Beacon Street, Brookline, and 486 Adams Street, Milton, for the practice of internal medicine

## AMERICAN COLLEGE OF SURGEONS SECTIONAL-MEETING SCHEDULE

The American College of Surgeons announces that six two-day sectional meetings will be held between January 7 and April 13, 1949, for physicians and surgeons, and professional personnel of hospitals. A seventh meeting to be held in the West in the latter part of April will be announced later. The latest developments in medical science and in hospital service will be presented at each meeting. The schedule follows:

DATE	CITY	HEADQUARTERS
January 7-8	Edgewater Park, Mississippi	Edgewater Gulf Hotel
January 14-15	Houston, Texas	Rice Hotel
February 11-12	Kansas City, Mo	Hotel President
March 15-16	Washington, D. C	Statler Hotel
March 21-22	Buffalo, New York	Statler Hotel
April 12-13	Edmonton, Alberta	MacDonald Hotel

Conferences for the hospital personnel and for the medical groups will run concurrently. A joint meeting of the two groups will open at 8 30 a m each day with the showing of medical motion pictures followed by separate sessions at 10-00 a m. Luncheons for the physicians and surgeons and for the hospital representatives, respectively, will be held daily. Separate afternoon sessions beginning at 2 00 o'clock will be held for the two groups. There will be a dinner meeting followed by a round-table conference on the first evening. According to Dr Dallas B Phemister of Chicago, president of the American College of Surgeons, several hundred persons are expected to attend each of the sectional meetings. Prominent local and visiting medical and hospital authorities will address the sessions.

## EARLY NEUROSYPHILIS

ISRAEL KOPP, M.D.\*

BOSTON

**I**NVASION of the central nervous system occurs in nearly all patients during the early stages of syphilis, usually during the first year of the infection. Early neurosyphilis is essentially a leptomeningitis. It is most often asymptomatic. The knowledge of its presence is of great importance since more intensive therapy and careful observation are necessary for these patients.

Early asymptomatic neurosyphilis can be detected only by spinal-fluid examination. The percentage of abnormal spinal fluids depends upon the time and frequency of the examination, ranging

neurosyphilis (tabes, paresis, optic atrophy and so forth).

The finding of a normal spinal fluid in early syphilis, of less than two years' duration, does not always indicate that neurosyphilis will not occur in the future. Neurosyphilis may develop despite what is commonly accepted as intensive and adequate therapy with mapharsen, bismuth or penicillin. For this reason it is essential that spinal-fluid examinations be repeated over a period of years before the patient can be given complete assurance that neurosyphilis will not develop. A

TABLE 1 *Spinal-Fluid Findings in Case 1*

DATE	WASSERMANN REACTION	CELL COUNT <i>per cc mm</i>	GLOBULIN	TOTAL PROTEIN <i>mg per 100 cc</i>	GOLD-SOL CURVE	COMMENT
1/10/44	Negative	5	Negative	—	Negative	Before treatment
3/ 2/44	± (0.5 cc.)	—	Negative	—	Negative	Before treatment

9/ 8/45	— (0.1 cc.)	197 lymphocytes	Trace	59	4444:21000	—
10/12/45	— (0.25 cc.)	5 lymphocytes	Negative	28	0023:00000	After malaria and penicillin therapy

from 9 per cent in primary syphilis to 16 and 48 per cent in early and late secondary syphilis.<sup>1</sup> The degree of spinal-fluid abnormality is also of importance, since Moore<sup>2</sup> has shown that with inadequate treatment parenchymatous neurosyphilis will develop in 70 to 80 per cent of patients in whom early examination revealed severe or so-called Group III changes.

Despite these facts, syphilis of the central nervous system has been looked upon by some as a late development of the disease. This attitude has been fostered by the failure to do spinal-fluid examinations in early syphilis, by the rather infrequent appearance of early symptomatic neurosyphilis (meningitis and thromboses) and by the late development of symptomatic parenchymatous

neurosyphilis. The following case reports bring out some important facts regarding the development, treatment and course of early neurosyphilis.

The following case reports bring out some important facts regarding the development, treatment and course of early neurosyphilis.

### CASE REPORTS

In the following case of early asymptomatic neurosyphilis with mild spinal-fluid abnormality the spinal fluid became normal after intensive mapharsen and bismuth therapy. A severe neurorelapse occurred ten months later.

**Case 1.** H. J. A., a 31-year-old man, developed a penile lesion in October, 1943. The blood Kahn reaction was positive on November 27 and December 6. He was given forty intravenous injections of mapharsen (0.060 gm each) and

\*Research fellow, Department of Psychiatry, Harvard Medical School; research associate, Department of Mental Health, Boston Psychopathic Hospital; assistant physician, Beth Israel Hospital; attending physician, Neuropsychiatric Service, Veterans Administration Hospital, West Roxbury, Massachusetts; formerly, chief, Neurosyphilis Section, Schick General Hospital, Clinton, Iowa.

sixteen intramuscular injections of bismuth subsalicylate (0.200 gm each) from March 10 to September 16, 1944. The results of spinal-fluid examinations are presented in Table 1.

Neurologic examination on August 30, 1945, was negative. The blood Kahn and Wassermann reactions were positive.

The patient was inoculated with tertian malaria on September 12 and was allowed ten paroxysms until October 6, 1945. He was also given one hundred and twenty doses of 30,000 units of penicillin intramuscularly at 3-hour intervals from September 30 to October 16, 1945.

This case provides an excellent example of the importance of repeated spinal-fluid examinations in early syphilis. The spinal fluid three months after the primary lesion and prior to any chemo-

The findings after combined penicillin and malaria therapy revealed the usual marked reduction in cell count and protein. Spinal fluid and clinical re-evaluations were recommended at six-month intervals until the spinal fluid becomes normal and then yearly for three years. Additional therapy, preferably penicillin, will be necessary if clinical or spinal-fluid relapse occurs.

In the following case of asymptomatic neurosyphilis with Group III spinal fluid and marked meningeal reaction nine months after seropositive primary syphilis and immediately after completion

The high cell count—223 per cubic millimeter, with 98 per cent lymphocytes—is indicative of a fairly severe meningeal reaction. Since the patient was free of symptoms and neurologic examination was negative, the neurorelapse would have been overlooked had not the spinal-fluid examination been repeated. This type of abnormal fluid is of considerable prognostic significance in the development of future parenchymatous neurosyphilis. Intensive therapy, occasionally reinforced by fever, is necessary if such an event is to be prevented. The finding of even slight spinal-fluid abnormalities in early asymptomatic neurosyphilis is of considerable importance and necessitates frequent clinical and spinal-fluid re-evaluations.

tions of bismuth subsalicylate (0.200 gm each) were given from March 20 to September 22. The blood Kahn and Wassermann reactions were positive after treatment. The spinal-fluid findings are presented in Table 2.

The patient was given a second course of thirty-one injections of mapharsen (0.060 gm each) and eight injections of bismuth subsalicylate (0.200 gm each) from December 4, 1944, to February 28, 1945, and sixty doses of 40,000 units of penicillin intramuscularly at 3-hour intervals from January 27 to February 6, 1945.

Central-nervous-system syphilis was detected shortly after intensive mapharsen and bismuth therapy for primary syphilis. The spinal-fluid abnormalities were severe (Group III). The high cell count indicated a marked meningeal reaction, but there were no symptoms of meningitis. Additional mapharsen, bismuth and penicillin therapy

resulted in a marked reduction of the cell count, but the spinal fluid remained abnormal. Though continued chemotherapy with trivalent arsenicals or penicillin often results in a normal spinal fluid in early neurosyphilis, malarial therapy was recommended. Repeated clinical and spinal-fluid evaluations are necessary for this patient, as recommended in Case 1.

In the following asymptomatic neurosyphilis with Group III spinal fluid ten months after seropositive primary syphilis followed treatment with penicillin, mapharsen and bismuth. Combined malaria and penicillin was then administered.

CASE 3 F R, a 32-year-old Negro, developed a penile lesion in September, 1944. The blood Kahn reaction was positive on September 7.

He was given 60 doses of 40,000 units of penicillin intramuscularly at 3-hour intervals from September 11 to September 18. Because healing of the penile lesion was slow, he

some hoarseness, as well as patchy areas of alopecia involving the scalp and eyebrows. Dark-field examinations of scrapings of the perianal lesion on May 8 and 9 revealed *Treponema pallidum*. A serologic test on May 8 revealed 240 Kahn units.

The patient was given sixty doses of 40,000 units of penicillin intramuscularly at 3-hour intervals from May 9 to May 15. The blood titer had fallen to 40 Kahn units on November 3.

The spinal-fluid findings 6 months after the secondary lesions had appeared and penicillin treatment had been instituted are presented in Table 4.

Neurologic examination was negative on November 17. The patient was inoculated with tertian malaria on January 12, 1946, and allowed nine paroxysms to January 31. He was given one hundred and twenty injections of 30,000 units of penicillin intramuscularly at 3-hour intervals from January 17 to February 1. Spinal-fluid examination after therapy was refused.

Penicillin therapy for secondary syphilis did not prevent the development of asymptomatic neurosyphilis with a Group III spinal fluid. The per-

TABLE 4 Spinal-Fluid Findings in Case 4

11/20/45	+ (0.1 cc.)	156 lymphocytes	Slight trace	57	55543321000

was also given forty intravenous injections of mapharsen (0.060 gm. each) and 16 intramuscular injections of bismuth subsalicylate (0.200 gm. each) from November, 1944, to July, 1945. The spinal-fluid findings are shown in Table 3.

Neurologic examination on September 1 was normal. The patient was inoculated with quartan malaria on September 25 and allowed ten paroxysms to November 10. Fever was also induced on four occasions by means of mixed typhoid vaccine intravenously. He was given one hundred and twenty doses of 30,000 units of penicillin intramuscularly at 3-hour intervals from October 28 to November 12.

Intensive chemotherapy, consisting of penicillin, mapharsen, and bismuth for primary seropositive syphilis, did not prevent the development of asymptomatic neurosyphilis with strong spinal-fluid abnormalities. Involvement of the nervous system was first detected ten months after the primary lesion had appeared and immediately after chemotherapy had been completed. Because of the strong abnormalities in the spinal fluid, malarial therapy combined with penicillin was given. This case reveals the importance of a spinal-fluid examination before the patient is discharged from treatment. Frequent clinical and spinal fluid re-evaluations are necessary, as recommended in Case 1.

In the following case there were marked spinal-fluid abnormalities (Group III) six months after penicillin treatment of secondary syphilis. The patient was also treated with combined penicillin and malaria.

CASE 4 A S P, a 29-year-old man, admitted repeated exposures in February and March, 1945. Lesions of the anus, penis, gums and tongue were noted on May 8. There was

sistence of positive serologic tests should cause one to suspect involvement of the central nervous system. The incidence of neurosyphilis following penicillin therapy of early syphilis is estimated as less than 2 per cent. Repeated courses of penicillin with or without mapharsen and bismuth might well have resulted in a normal spinal fluid since this was a case of early asymptomatic neurosyphilis. However, as long-continued therapy and observation were not possible, combined malaria and penicillin therapy were recommended. If it is among this group that the future paresis or tabes is most apt to develop, early malarial therapy should be of great benefit.

In the following case of asymptomatic neurosyphilis with progressively severe abnormalities in the spinal fluid despite intensive chemotherapy for secondary syphilis, a reversal of Group III spinal fluid to normal occurred after penicillin, malaria and typhoid vaccine fever.

CASE 5 M E H, a 28-year-old Negro, developed a primary lesion in December, 1943. This was followed by a right inguinal adenitis and a maculopapular rash of the face and back. Dark-field examination of the penile lesion was negative. The blood Kahn and Wassermann reactions were positive in December, 1943, and January, 1944. Forty intravenous injections of mapharsen (0.060 gm. each) and fifteen intramuscular injections of bismuth subsalicylate (0.200 gm. each) were given from January 18 to August 31.

The blood Kahn reaction became negative after treatment, remaining so until February, 1945, and then relapsing to positive. The results of the spinal-fluid examinations are shown in Table 5.

The patient was given eighty doses of 50,000 units intramuscularly of penicillin at 3-hour intervals from March 21 to March 31. He was inoculated with quartan malaria on May 24, and allowed eight paroxysms until July 26. Fever was also induced on seven occasions by means of mixed typhoid vaccine intravenously.

One year after a primary lesion and about three months after completion of intensive chemotherapy, the spinal fluid revealed an increase in cells, which was indicative of central-nervous-system involvement. Two months thereafter the spinal-fluid

developed in February, 1944. A diagnosis of lymphogranuloma inguinale was made. He was given sulfonamide therapy. The lymph nodes became less tender but remained enlarged for 3 or 4 months. A serologic test was positive in January and February, 1945. The results of spinal-fluid examination are presented in Table 6.

He was given fifteen intravenous injections of mapharsen (0.060 gm each) and five intramuscular injections of bismuth subsalicylate (0.200 gm each) from February 26 to April 13. The spinal fluid reverted to normal in 5 months.

Neurologic examination on June 30 was negative, as was a Frei test on July 7. The blood Kahn and Wassermann reactions were positive.

abnormalities were severe (Group III). The fluid showed some improvement after the administration of penicillin and became practically normal after fever therapy.

It is possible that the spinal fluid would eventually have become normal as a result of penicillin therapy alone. Moore<sup>3</sup> states that the speed and extent of disappearance of all spinal-fluid abnormalities following penicillin depends upon the degree of these abnormalities before treatment.

From July 12 to July 19 the patient was given sixty injections of 40,000 units of penicillin intramuscularly at 3-hour intervals.

The neurosyphilis in this case was asymptomatic and evidently early. The penile lesion in December, 1943, was probably a chancre and not lymphogranuloma inguinale, since a Frei test two and a half years later was negative. A moderate amount of mapharsen and bismuth therapy had rapidly reversed a Group III spinal fluid to normal. This

TABLE 6 Spinal-Fluid Findings in Case 6

and the duration of the syphilitic infection. In a series of 91 patients with asymptomatic neurosyphilis, 48 of less than four years' duration, observed on an average for about nine months, spinal-fluid normality once obtained seemed to be sustained. Serologic relapse like that in Case 5, which should always alert one to the possible presence of early neurosyphilis, demands a spinal-fluid examination.

In the following case of early asymptomatic neurosyphilis with marked spinal-fluid abnormalities, the spinal fluid became normal after a moderate amount of mapharsen and bismuth therapy.

CASE 6. J. L. R., a 24-year-old man, had negative serologic tests in December, 1942. A penile lesion appeared 7 to 10 days after exposure in December, 1943. Dark-field examinations were negative. Left inguinal adenopathy

is not uncommon in early asymptomatic neurosyphilis. However, repeated spinal-fluid and clinical re-evaluation for four years at least is necessary since relapse is not uncommon with this degree of abnormality.

In the following case of early meningo-vascular neurosyphilis with right cerebral thrombosis spinal-fluid abnormalities persisted after two courses of penicillin, malaria therapy was instituted.

CASE 7. H. J. B., a 27-year-old man, had a negative serologic test on December 15, 1943. On May 23, 1945, a central weakness of the left facial muscles developed, accompanied by a left hemiparesis. The spinal-fluid findings are shown in Table 7.

The Wassermann and Kahn reactions of the blood were positive on June 8. From June 23 to July 3 eighty doses of

50,000 units of penicillin were administered intramuscularly at 3-hour intervals

On August 8 neurologic examination revealed brisk and equal reflexes and a left Babinski sign. The serologic tests were again positive. The subsequent spinal-fluid findings are presented in Table 7.

The patient was given a second course of penicillin, consisting of one hundred and twenty doses of 30,000 units intramuscularly at 3-hour intervals from September 7 to 22. Since the protein and cell count remained elevated after completion of penicillin therapy, he was inoculated with tertian malaria and allowed eleven paroxysms.

Early symptomatic neurosyphilis is not common. The patient gave no history of primary or secondary syphilis. The first sign of neurosyphilis was weakness of the left side of the face and left side

in July, 1945, he was given four doses of 50,000 units of penicillin intramuscularly. He was again given some penicillin therapy, the exact amount not known, in September because of tonsillitis.

On October 3, he experienced a grand mal seizure with involvement of the right side of the face and right upper extremity. On October 5, 8 and 9 similar episodes without loss of consciousness occurred. During this time he complained of left frontal headaches. Central weakness of the right facial muscles and slurring of speech were observed on October 13.

The quantitative titer of the blood on October 15 and 15 was 10 Kahn units. X-ray study of the skull was negative. The spinal-fluid pressure and dynamics were normal. A sugar tolerance test was normal. The spinal-fluid findings are presented in Table 8.

From October 15 to 22 sixty doses of 40,000 units of penicillin were administered intramuscularly at 3-hour intervals.

TABLE 7 Spinal-Fluid Findings in Case 7

DATE	WASSERMANN REACTION	CELL COUNT <i>per cu mm</i>	GLOBULIN	TOTAL PROTEIN <i>mg per 100 cc</i>	GOLD-SOL CURVE	COMMENT

of the body. This was indicative of a vascular lesion, but pure syphilitic arteritis rarely occurs without an associated meningitis or meningo-encephalitis. Though syphilis had been suspected as the cause after the finding of 284 cells per cubic millimeter in the spinal fluid, the Wassermann reaction of the spinal fluid and blood had not been determined. Strong spinal-fluid abnormalities and

Neurologic examination on October 30 revealed central weakness of the right facial muscles, and the reflexes of the right upper extremity were more active than those on the left.

The serologic titer on November 2 was 40 Kahn units, the blood Wassermann reaction was positive.

From January 9 to 16, 1946, the patient was given a second course of penicillin consisting of sixty doses of 40,000 units intramuscularly at 3-hour intervals.

The serologic titer was 10 Kahn units and the blood Wassermann reaction was negative on January 17.

		5 lymphocytes				

a positive serologic test were found two weeks thereafter. Spinal-fluid abnormalities were still present after two courses of penicillin, and it was considered best to administer malaria therapy. Clinical and spinal-fluid re-evaluations, as in Case 1, were recommended.

In the following case of early meningovascular neurosyphilis with Jacksonian attacks moderately severe spinal-fluid abnormalities rapidly returned to normal after 2,400,000 units of penicillin had been administered.

CASE 8 R E R, a 27-year-old man, had a negative serologic test in August, 1942. Because of a gonorrheal infection

A convulsive episode may be the first indication of neurosyphilis, early or late. This is due to a thrombosis of a cortical vessel that occasionally occurs in the leptomeningitis of neurosyphilis. The moderately severe spinal-fluid abnormalities rapidly reverted to normal after 2,400,000 units of penicillin had been administered. The patient will require clinical and spinal-fluid re-evaluations for at least three years. The convulsive episodes disappear in most cases with adequate anti-syphilitic therapy. If they recur, anticonvulsants should be given.

In the following case of syphilitic meningitis with cerebral thrombosis in early syphilis the patient suffered a neurorelapse

CASE 9 W R C, a 21-year-old man, developed a penile lesion in December, 1942. He received three intravenous treatments. A serologic test on February 12 and March 26, 1943, was positive. The spinal-fluid findings are presented in Table 9.

He was given thirty-nine injections of mapharsen (0.060 gm each) and seventeen of bismuth subsalicylate (0.200 gm each) from May to December.

From December, 1944, on he experienced frontal headaches of 2 or 3 hours' duration. Dizzy spells occurred in May, 1945. Numbness of the right forearm and the fourth and fifth fingers over 1 week's time was present in August. He was aphasic from September 1 to 8. There was also weakness

## DISCUSSION

The cases reported above are examples of early asymptomatic and symptomatic neurosyphilis. Of 154 cases of asymptomatic neurosyphilis from November, 1944, to February, 1946, 25 (15 per cent) were of less than two years' duration when the patients were first seen. Spinal-fluid abnormalities of varying degree were found from the secondary stage of syphilis on. These abnormalities may clear with chemotherapy, mapharsen, bismuth or penicillin, but occasionally relapse occurs despite intensive therapy.

TABLE 9 Spinal-Fluid Findings in Case 9

DATE	WASSERMANN REACTION	CELL COUNT <i>per cu mm</i>	GLOBULIN	TOTAL PROTEIN <i>mg per 100 cc</i>	GOLD-SOL CURVE	COMMENT
5/8/43	Negative (0.5 cc)	110	Negative	—	—	—

of the right upper extremity and numbness of the ulnar portion of the forearm.

A serologic test on September 7 revealed 40 Kahn units. Physical examination showed dysarthria, loss of the finer movements of the right hand and absent right abdominal reflexes.

The serologic titer on October 18 was 40 Kahn units, the blood Wassermann reaction was positive.

He was inoculated with tertian malaria on November 17 and allowed eleven paroxysms until December 9. He was also given one hundred and twenty doses of 30,000 units of penicillin intramuscularly at 3-hour intervals from November 22 to December 7.

This patient's spinal fluid revealed an increase in cell count five months after the appearance of a primary lesion. The spinal fluid was normal immediately after the completion of seven months of intensive mapharsen and bismuth therapy. One year later, progressively severe symptoms referable to the central nervous system developed. Neurorelapse with spinal-fluid abnormalities, Group III in type, were found twenty-two months after a normal spinal-fluid had been obtained and three years after the primary lesion.

The sequence of events in this patient again emphasizes the fact that one cannot rely on a single normal spinal-fluid specimen in early neurosyphilis, especially an examination performed shortly after the completion of chemotherapy. In addition, the necessity of adequate therapy for syphilitic meningitis has been stressed by various observers, since two thirds of inadequately treated patients have developed parenchymatous and late meningo-vascular neurosyphilis.<sup>4</sup> Since the patient's syphilis was of three years' duration, malaria therapy was given without hesitation.

These cases support the advice that treatment for early syphilis cannot be considered satisfactory unless a spinal-fluid examination is done before the patient is discharged. If the spinal fluid is normal, adequate follow-up study requires that it should be normal again at least four years after the primary lesion. If spinal-fluid abnormalities are present during the first two years of the infection, additional chemotherapy (formerly trivalent arsenicals and bismuth, now penicillin) is necessary, since early neurosyphilis will respond most often to chemotherapy alone. If marked improvement or a normal spinal fluid does not result within a year, fever therapy is given. However, if the infection is of more than two years' duration when the patient is first seen and significant spinal-fluid abnormalities are present, fever therapy should be administered immediately, combined now with penicillin. Further experience will be necessary before it can be determined whether penicillin alone will be adequate in these cases, as has been reported by some observers.<sup>5</sup>

The majority of the patients with early asymptomatic neurosyphilis included in this study had already received chemotherapy consisting of trivalent arsenicals and bismuth. A few had received penicillin. In many cases the treatment was considered adequate according to present standards. With the introduction of penicillin, it is now necessary to determine new methods for the treatment of neurosyphilis. It is already apparent that the incidence of neurosyphilis has been reduced considerably as a result of the treatment of early

sphilis with penicillin. Used alone, the drug has proved very effective in the treatment of syphilitic meningitis, asymptomatic and meningo-vascular neurosyphilis and, in the opinion of some observers, in parenchymatous neurosyphilis.

It is also evident from the cases reported above that malaria therapy was administered quite early for the treatment of neurosyphilis. Undoubtedly the spinal-fluid abnormalities in some cases would have responded to additional chemotherapy alone. Since it is especially among the patients with severe spinal-fluid abnormalities that future parenchymatous neurosyphilis may develop, and since circumstances prevented long-continued chemotherapy and observation in this group, malaria therapy was given early. Clinical and spinal-fluid evaluations of these patients over the years should be of considerable interest in demonstrating the preventive effect of combined malaria and penicillin therapy of early neurosyphilis upon the development of late parenchymatous disorders.

Prior to the introduction of penicillin, Moore<sup>6</sup> had expressed the opinion that fever therapy in asymptomatic neurosyphilis is seldom necessary except in patients with Group III spinal fluids and those of other groups in whom at least eighteen months of other forms of treatment had failed to effect serologic reversal. Malaria was not recommended by him if the infection was recent until the patient had had at least six months' treatment with the arsphenamines and heavy metal given for the treponemicidal effect. The latter was advised because of the great probability of infectious mucocutaneous relapse. It is possible that this objection can now be overcome by the concurrent use of penicillin, with its pronounced treponemicidal effect, and malaria.

## SUMMARY

Invasion of the central nervous system in syphilis is early, occurring in nearly all patients, usually within the first year of the infection.

Early neurosyphilis is most often asymptomatic but occasionally is symptomatic. When asymptomatic, it can be detected only by spinal-fluid examination.

Neurosyphilis may develop despite the administration of what is commonly accepted as adequate chemotherapy for early syphilis.

Complete reliance cannot be placed on the finding of a single normal spinal-fluid specimen in early syphilis before or immediately after therapy.

A negative spinal-fluid examination four years or more after the primary lesion, regardless of whether therapy has been given, is good assurance against the future development of meningo-vascular or parenchymatous neurosyphilis.

The treatment of early syphilis with penicillin has reduced considerably the incidence of early neurosyphilis. Penicillin alone is of great benefit in the therapy of neurosyphilis of the asymptomatic, meningo-vascular and meningitic types. Further experience is necessary to determine its value as the sole treatment for parenchymatous (general paresis, tabes dorsalis, optic atrophy and so forth) neurosyphilis.

## HOSPITAL AND HEALTH-CENTER FACILITIES IN MASSACHUSETTS

### The Massachusetts State Plan for the Administration of Public Law 725 (Hospital Survey and Construction Act)

VLADO A. GETTING, M.D., DR. P.H.,\* A. DANIEL RUBENSTEIN, M.D.,† AND CLAIRE F. RYDER, M.D.‡

BOSTON

THE acute shortage of hospital beds experienced everywhere in the country during the past few years resulted in 1946 in the enactment of Public Law 725 by the Seventy-Ninth Congress. This act, the Hospital Survey and Construction Act, previously known as Senate Bill 191, or the Hill-Burton Bill, was the first and only bill to be endorsed in Congressional hearings by the American Public Health Association, the American Hospital Association and the American Medical Association. The purpose of the Act is to enable communities throughout the nation to construct hospitals and health-center facilities under a federal grants-in-aid program for a period of five years beginning July 1, 1947. Such facilities are to be provided on the basis of need according to plans developed by each state. The federal Government is contributing a third of the cost of constructing and equipping hospitals and health centers, and the remaining two thirds is derived from sources within the state.

Of the \$75,000,000 authorized by Congress for hospital construction during the first year of the program, approximately \$1,600,000 has been allotted to Massachusetts. The amount of the grant to Massachusetts for the five-year period of the program totals approximately \$8,000,000. Since each dollar of federal grants must be matched by two dollars from state or local sources, the total expenditure under this program in Massachusetts amounts to \$24,000,000. State, county, municipal and private nonprofit hospitals may be assisted if individual projects are approved by the state operating agency (usually the health department) and the United States Public Health Service, and provided that the project is in accord with the plan<sup>1</sup> formulated by the state agency to meet the needs for additional facilities. The Massachusetts State Plan was approved by the Surgeon General of the United States Public Health Service on December 2, 1947. The state agency in Massachusetts directly responsible for the administration of Public Law 725 is the Department of Public Health. For the administration of this Act, a bureau of hospital survey and construction has been created, and an advisory council to the state agency has been appointed.

In accordance with the regulations promulgated by the United States Public Health Service regarding Public Law 725, the Commonwealth of Massachusetts has been divided into three types of hospital service areas—namely, base, intermediate and rural.

A base area is defined as one that, irrespective of population, contains a teaching hospital of a medical school, or one that has a total population of at least 100,000 and contains or will contain a general hospital of 200 beds or more providing internships and at least two or more residencies. An intermediate area has at least 25,000 persons and contains or will contain a general hospital of 100 beds or more. A rural area has a population under 25,000.

For the purposes of the Act, the term "hospital" includes public-health centers, general, tuberculosis, mental-disease and chronic-disease hospitals, and related facilities such as laboratories, outpatient departments, nurses' homes and schools and all service facilities operated in connection with such institutions. Federal hospitals and institutions providing primarily domiciliary care are not included in the above definitions.

Bed allowance for general hospitals is based upon the state's population density. In Massachusetts, with more than 12 persons per square mile, the maximum state allowance for general hospital beds is 4.5 per thousand population. Standards for area ratios also depend on population density. In Massachusetts, area ratio standards are as follows: base areas, 4.5 beds per thousand population, intermediate areas, 4 beds per thousand population, and rural areas, 2.5 beds per thousand population.

The differences in the number of beds allowable under the state and area ratios may be totaled and thus constitute a pool of general-hospital beds. Pool beds may be distributed throughout the state at the discretion of the state agency according to the needs of various areas. The number of beds required to provide adequate hospital services for the care of tuberculosis patients amounts to two and a half times the average annual deaths from tuberculosis, for mental patients, 5 beds per thousand population, and for patients with chronic diseases, 2 beds per thousand population. The total number of public-health centers allowed shall not exceed 1 for 30,000 persons.

\*Commissioner, Massachusetts Department of Public Health.

†Director of Hospital Survey and Construction.

‡Epidemiologist, Hospital Survey and Construction.

In the development of the hospital-construction program, consideration must be given to each of the five categories of facilities: general, tuberculosis and mental and chronic-disease hospitals and public-health centers. New hospitals and additions to existing hospitals have priority over replacements, with the exception of hospitals that constitute a public hazard and should be replaced. It is the intent of the law to provide facilities in areas of greatest need. Special attention must be given to projects in rural areas or in communities of low economic resources.

### EXISTING FACILITIES

In the development of the state plan for the administration of the Act, a survey of existing hospital and health-center facilities in Massachusetts has been completed. There are in the Commonwealth a total of 219 hospitals with a normal bed capacity of 44,044 beds. Of these institutions, 147 are general hospitals with 16,968 beds, and 24 allied special hospitals with 2210 beds (Table 1).

It is noteworthy that of the 147 general hospitals, 92 have 100 beds or less, 44 have 100 to 249 beds, and only 11 have 250 beds or more (Table 2).

There are 20 tuberculosis institutions with a total bed capacity of 3299 (Table 1). Of these,

Existing facilities for the care of patients with long-term illness are entirely inadequate in the Commonwealth as they are everywhere else in the country. There are now only 1100 beds for patients with chronic diseases in Massachusetts hospitals. How this shortage is to be overcome is a matter of debate. In Springfield, one hospital has set aside a complete ward for such patients. Although this ward was set up more than ten years ago, certain patients admitted at the time of its inception are still occupying beds in this institution. The problem is even more acute for certain categories of patients, such as those with terminal cancer. Ordinarily, these patients are not accepted

TABLE 2 *Distribution of General Hospitals by Size*

SIZE	TOTAL NUMBER	
	HOSPITALS	BEDS*
Less than 25 beds	25	436
25-49 beds	32	1 115
50-99 beds	37	2,460
100-249 beds	44	7 178
250-499 beds	8	2,597
More than 500 beds	5	3 184
Totals	147	16 968

\*The figures referring to number of beds indicate the normal bed capacity—that is, number of beds for which the hospital was built. In many instances because of overcrowding this figure is smaller than the actual number of beds in use for inpatient care (complement).

Nervous and mental	24	21 000
Chronic and convalescent	4	517
Grand totals	219	44 044

\*The figures referring to number of beds indicate the normal bed capacity—that is, the number of beds for which the hospital was built. In many instances because of overcrowding this figure is smaller than the actual number of beds in use for inpatient care (complement).

4 are nongovernmental, nonprofit associations, and the remaining 16 are governmental hospitals. Of the latter, 12 are owned by cities or counties and provide nearly 2000 beds, primarily for the care of the patients with local settlements, and 2 are state institutions having a bed capacity of about 600 beds. In addition, there are 2 state hospitals caring for patients with extrapulmonary tuberculosis and tuberculosis in children. If tuberculosis units in general or board of health hospitals are included, the total number of existing beds for the care of tuberculosis is 3611.

In Massachusetts there are 24 mental hospitals with a normal bed capacity of 21,050 (Table 1). Of these, 12 institutions with a total of 604 beds are nongovernmental, and the remaining 12 with 20,446 beds are state owned.

for admission into general hospitals for indefinite or prolonged periods of stay. Nursing homes and convalescent homes are often too inadequately staffed to care for them. In summary, there are practically no facilities for the patient requiring terminal care.

Although each of the 351 municipalities is required by law to carry out certain governmental functions in the field of public health, as defined by Public Law 725, there are but 11 health centers in the Commonwealth. Of these, 10 are in Boston proper. The other is the public-health center in Averb, maintained by the Nashoba Health Unit, a union of several towns in the north central section.

### HOSPITAL SERVICE AREAS

In keeping with requirements of Public Law 725, all cities and towns in Massachusetts, singly or in groups are designated as the service areas of existing or proposed general hospitals. Accordingly, the Commonwealth was divided into 70 general-hospital service areas. Each of these areas contains at least one general hospital, with the exception of one area (Athol) where a new hospital facility has been proposed. Determination of the service area was based primarily on available data regarding the flow of patients into the hospital. Other factors taken into consideration were location of trading centers and lines of communication. Subsequently, each hospital service area was clas-

sified as base, intermediate or rural (the prerequisites of these area types were described above) Of the 70 hospital service areas in Massachusetts, 4 are base, 43 intermediate, and 23 rural

In addition, the state plan provides a method whereby each hospital service area will be co-ordinated with all others so that a uniform pattern of hospital care shall be formulated for the entire Commonwealth Theoretically, the base areas should offer consultation and diagnostic services to the intermediate areas, which, in turn, offer simi-

which the number assigned by area ratio is insufficient for the needs of the jurisdiction Pool beds were assigned in proportion to high occupancy rates, excessive bed-death ratios and special problems such as seasonal increases in population Of the 1661 pool beds, the greatest number was allocated to base areas (1011 beds), intermediate areas being allotted 440 and rural areas 210 beds (Table 3)

The number of existing and needed beds according to the several categories is as follows there are 18,224 general-hospital beds, whereas 23,829 beds

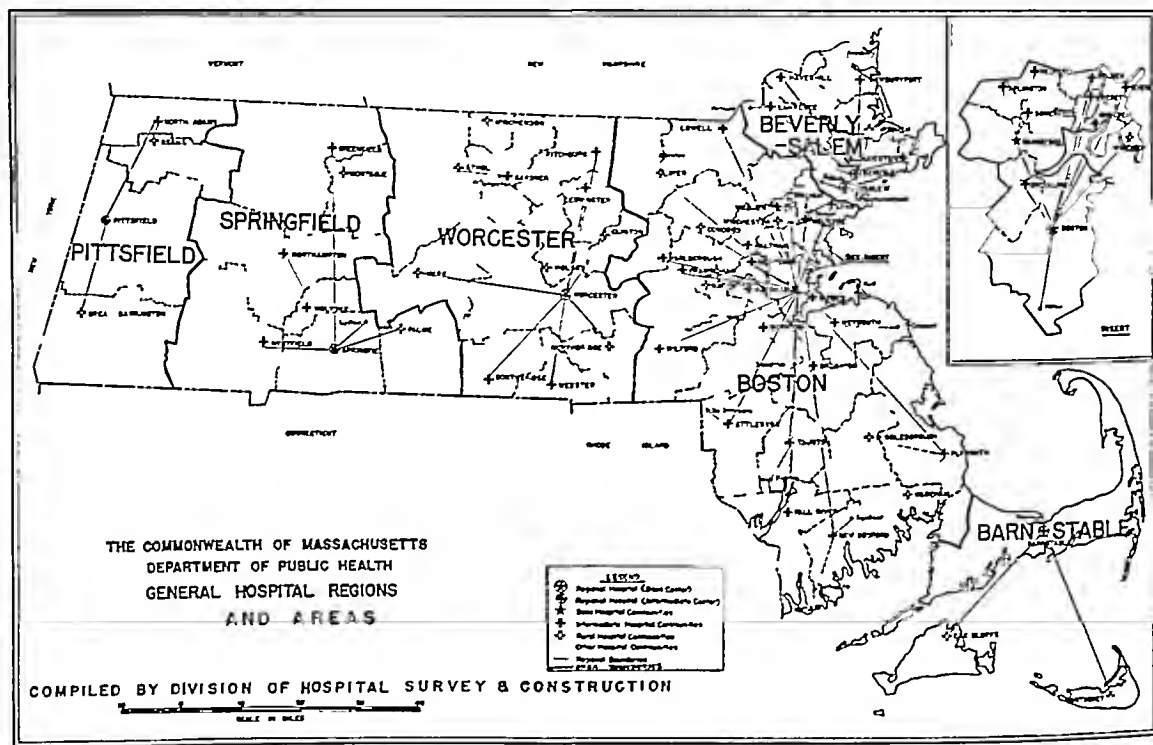

FIGURE 1 Hospital Service Areas in Massachusetts

lar service to rural areas To allow for this exchange of facilities, Massachusetts was divided into 6 regions of which 3 are composed of intermediate and rural areas, and the other 3 contain in addition base areas The former are the Beverly-Salem, Barnstable and Pittsfield regions, and the latter, the Boston, Worcester and Springfield regions (Fig 1)

#### DETERMINATION OF NEEDS FOR HOSPITALS AND HEALTH CENTERS

The number of beds apportioned to each general hospital service area is determined according to the formula established by law as mentioned above Of 3944 beds added by area ratio in Massachusetts, nearly all (3285 beds) went to intermediate areas and only 454 and 205 to base and rural areas respectively Pool beds may be allocated to areas in

are needed according to Public Law 725, making a deficit of 5605 beds For the care of tuberculosis, Massachusetts has in existence 3604 beds, 4408 beds are needed Therefore, 804 additional beds must be provided For patients with mental disease, there are 21,102 beds, 1738 additional beds are needed, since the total beds allowed are 22,840 Finally, for chronic-disease hospital facilities, there are only 1100 beds in existence, 9136 are needed, and therefore, a deficit of 8036 exists The figures of need met in these four categories of facilities are 76 per cent for general-hospital beds, 82 per cent for tuberculosis, 92 per cent for mental-disease and 12 per cent for chronic-disease beds (Fig 2)

The state plan must also give consideration to the need for health centers in Massachusetts For the Commonwealth as a whole, 31 public-health

centers are being proposed. For the most part, these centers have been allocated to the larger cities and towns with a population of 30,000 or more. It should be noted, in accordance with the ratio of 1 health center for each 30,000 persons, that many of the larger cities could plan for more than one health center provided that matching local funds were available. In addition, a health center has

greater financial resources than communities low in Dr Lambie's rating.

The primary consideration in developing the priority schedule was the percentage by which the existing acceptable hospital beds within an area met the total needs of that area. From the percentage of need met, additional deductions were made for rural areas and those of low financial

been proposed in Amherst for the Connecticut Valley State Health District and another for Barnstable County.

A recent report issued by the Special Commission to Study and Investigate Certain Public Health Matters<sup>2</sup> will suggest a plan to provide full-time health service for the entire Commonwealth. The findings of the Recess Commission will be given full consideration by the state agency and the advisory council in future planning of adequate health-center facilities, including physical plant and personnel.

#### PRIORITY SCHEDULES

To facilitate the equitable distribution of federal funds available for the construction of general hospitals, a system of priorities has been developed. This system gives full consideration to the provisions required in Public Law 725 and the federal regulations—namely, the relative need for beds in an area, rural character of the hospital service area and the financial rating.

Percentage of need met is determined by division of the total number of existing acceptable beds in each area by the total number of beds needed in the area, this figure being multiplied by 100 for the percentage. Rural character is established by the Act as any area with a population less than 25,000.

In 1941, Dr Morris B. Lambie<sup>3</sup> conducted a study of the municipal finances of the 351 cities and towns in the Commonwealth at the Harvard Graduate School of Public Administration. His comparative rating of these municipalities was based on three-year averages of three factors: tax rates, assessed per capita valuation, and direct tax per capita. According to these criteria, the municipalities were classified into eleven categories. Communities in the first grouping have relatively

rating. The final figure determined the standing in the priority scheme (Table 4).

The priority scheme for chronic-hospital projects has been computed in the same manner as for general hospitals, and is based primarily on the percentage of need met. Metropolitan areas of greatest population density will stand highest in

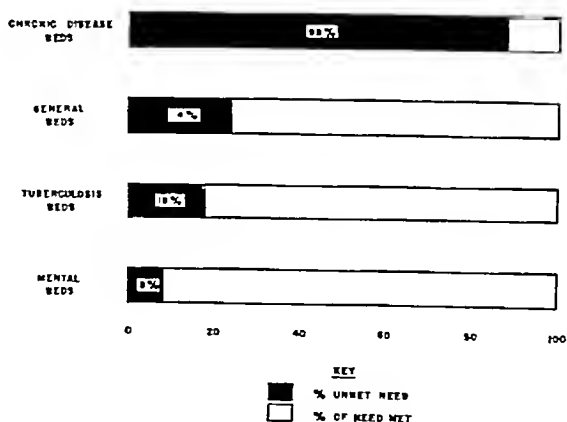

FIGURE 2 *Need for Additional Hospital Beds in Massachusetts*

the scheme. With respect to general hospitals it became apparent that strict application of the federal formula favored rural and intermediate areas rather than base areas. It was believed that construction of chronic-hospital units in metropolitan areas would compensate in part for the low standing in the priority schedule of the base areas. It will therefore be possible to allocate federal funds for chronic-hospital projects in such areas as Boston, Worcester, Springfield and Pittsfield.

The need for public-health centers in the Commonwealth is so great that no attempt has been made to establish a priority scheme for this cate-

sified as base, intermediate or rural (the prerequisites of these area types were described above) Of the 70 hospital service areas in Massachusetts, 4 are base, 43 intermediate, and 23 rural

In addition, the state plan provides a method whereby each hospital service area will be co-ordinated with all others so that a uniform pattern of hospital care shall be formulated for the entire Commonwealth Theoretically, the base areas should offer consultation and diagnostic services to the intermediate areas, which, in turn, offer simi-

which the number assigned by area ratio is insufficient for the needs of the jurisdiction Pool beds were assigned in proportion to high occupancy rates, excessive bed-death ratios and special problems such as seasonal increases in population Of the 1661 pool beds, the greatest number was allocated to base areas (1011 beds), intermediate areas being allotted 440 and rural areas 210 beds (Table 3)

The number of existing and needed beds according to the several categories is as follows there are 18,224 general-hospital beds, whereas 23,829 beds

been proposed in Amherst for the Connecticut Valley State Health District and another for Barnstable County.

A recent report issued by the Special Commission to Study and Investigate Certain Public Health Matters<sup>2</sup> will suggest a plan to provide full-time health service for the entire Commonwealth. The findings of the Recess Commission will be given full consideration by the state agency and the advisory council in future planning of adequate health-center facilities, including physical plant and personnel.

#### PRIORITY SCHEDULES

To facilitate the equitable distribution of federal funds available for the construction of general hospitals, a system of priorities has been developed. This system gives full consideration to the provisions required in Public Law 725 and the federal regulations—namely, the relative need for beds in an area, rural character of the hospital service area and the financial rating.

Percentage of need met is determined by division of the total number of existing acceptable beds in each area by the total number of beds needed in the area, this figure being multiplied by 100 for the percentage. Rural character is established by the Act as any area with a population less than 25,000.

In 1941, Dr Morris B. Lambie<sup>3</sup> conducted a study of the municipal finances of the 351 cities and towns in the Commonwealth at the Harvard Graduate School of Public Administration. His comparative rating of these municipalities was based on three-year averages of three factors: tax rates, assessed per capita valuation, and direct tax per capita. According to these criteria, the municipalities were classified into eleven categories. Communities in the first grouping have relatively

rating. The final figure determined the standing in the priority scheme (Table 4).

The priority scheme for chronic-hospital projects has been computed in the same manner as for general hospitals, and is based primarily on the percentage of need met. Metropolitan areas of greatest population density will stand highest in

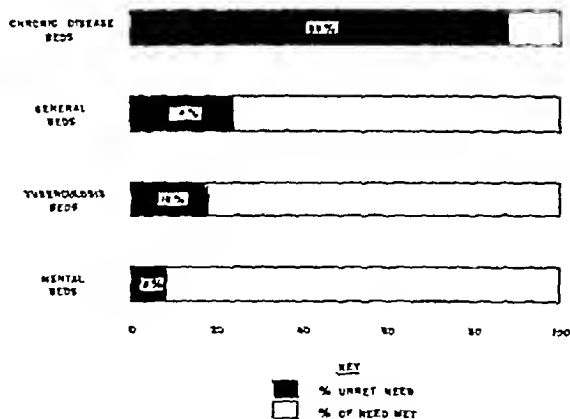

FIGURE 2 *Need for Additional Hospital Beds in Massachusetts*

the scheme. With respect to general hospitals it became apparent that strict application of the federal formula favored rural and intermediate areas rather than base areas. It was believed that construction of chronic-hospital units in metropolitan areas would compensate in part for the low standing in the priority schedule of the base areas. It will therefore be possible to allocate federal funds for chronic-hospital projects in such areas as Boston, Worcester, Springfield and Pittsfield.

The need for public-health centers in the Commonwealth is so great that no attempt has been made to establish a priority scheme for this cate-

gory Applications will be considered as they are submitted It is expected that at least some of the larger communities will take advantage of federal assistance for the construction of health centers

As indicated above, the need for tuberculosis and mental beds is relatively less than that for beds in chronic and general hospitals It has been determined that at least for the first two years of the program, federal assistance will be devoted to the construction of general and chronic hospitals and public-health centers

The federal funds provisionally allotted for these three categories during the fiscal years 1948

TABLE 4 Rank of General-Hospital Areas in First Two Priority Groups (1947-1948)

PRIORITY	AREA NO	AREA NAME
A-1	R-17	Athol
A-2	I-18	Needham
A-3	I-17	Medford
A-4	R-12	Northbridge

B-15	I-28	Melrose

and 1949 are \$1,177,128 for general hospitals, \$1,119,707 for chronic-disease hospitals, and \$574,209 for public-health centers The total amount of federal funds is \$2,871,044, representing an allotment of \$3,190,050, less a 10 per cent contingency fund for rising prices

During the first year of the program (1947-1948) five applications for new construction were approved The total number of beds to be added by these projects is approximately 300, of which 225 are of the general-hospital and 75 of the chronic-hospital category.

### Discussion

From Table 3 it is apparent that 50 per cent of existing hospital beds are in base areas that have 35 per cent of the population, whereas 44 per cent of the beds are in intermediate areas with 57 per cent of the population The figures of the rural areas are more nearly equal—namely, 57 per cent of the beds and 77 per cent of the population

After application of the federal formulas developed under Public Law 725, the discrepancies between the percentage of population and the percentage of total beds needed in base and intermediate areas are diminished but not to a marked degree In other words, the general pattern of the distribution of general-hospital beds in suburban and rural areas

has not been altered to a marked extent It was believed that general hospitals in Massachusetts have grown in accordance with the need of the population for this type of medical facility It was the policy of the state agency in setting up the plan not to interfere with this natural development.

It is expected that the priority scheme for the general-hospital category will be altered for the second year of the program to take into account obsolescent and substandard facilities Several of the general hospitals in Massachusetts were built at the turn of the century and are obsolete according to modern specifications Many are frame buildings or of substandard construction in other respects It is apparent, therefore, that many beds will be declared noncomputable as far as this plan is concerned This will alter considerably the priority standing of many areas that are now low in the schedule to a much more favorable position

Funds allocated by the federal Government for this program are inadequate to fulfill the entire need within the Commonwealth The state plan indicates an over-all lack of 16,183 beds in all categories A conservative estimate for the cost of building these beds is roughly \$190,000,000, exclusive of public-health centers It is apparent, therefore, that the total of \$24,000,000 that would be spent under this program is by no means adequate to construct all necessary facilities The cost of construction has risen to such a degree that without federal assistance many projects that have been planned will not be undertaken All of this may be taken as evidence that Public Law 725 is meeting a great need in the Commonwealth

### SUMMARY

A survey of existing hospital facilities revealed that there are 219 hospitals in Massachusetts with a normal bed capacity of 44,044

In accordance with the provisions of Public Law 725, the Commonwealth was divided into 70 general hospital service areas of which 4 are base, 43 intermediate and 23 rural In addition, to provide an integrated hospital system, 6 regions were formed, composed of the service areas mentioned above

By application of the formulas contained in the Act, it was found that there is a deficit of 16,183 beds, of which 5605 are general, 804 tuberculosis, 1738 mental-disease and 8036 chronic-disease beds

A priority schedule based primarily upon need for additional beds has been established for general and chronic hospitals

PNEUMOCOCCAL PNEUMONIA TREATED WITH AQUEOUS PENICILLIN AT  
TWELVE-HOUR INTERVALS\*

PHILIP A. TUMULTY, M.D.,† AND GORDON ZUBROD, M.D.‡

BALTIMORE

THE efficacy of penicillin in the treatment of patients with pneumococcal lobar pneumonia is well established.<sup>1,2</sup> However, the manner in which it may be employed to yield the best therapeutic results and with the least discomfort to the patient is still debated. It has been considered that to achieve maximum therapeutic response the blood concentration of penicillin must be maintained constantly at a level greater than the penicillin sensitivity of the particular organism.<sup>3</sup> Because of this assumption penicillin has generally been administered either in aqueous solution at frequent intervals or in some repository form. On the other hand, it has not been demonstrated either experimentally or clinically that this is necessary or desirable.<sup>4</sup> The relation of dosage frequency to therapeutic effectiveness has been examined in a streptococcal infection in mice treated with aqueous penicillin G.<sup>5</sup> The drug was just as effective when given once a day as when given more frequently. Similar results have been reported by others in the treatment of experimental infections in mice.<sup>6-10</sup> A few investigators have successfully employed aqueous penicillin given at infrequent intervals in pneumococcal lobar pneumonia,<sup>11</sup> subacute bacterial endocarditis<sup>12</sup> and pharyngitis due to the beta-hemolytic streptococcus.<sup>13</sup> It seemed worth while, therefore, to extend these observations to the treatment of patients.

## PLAN OF STUDY

Pneumococcal lobar pneumonia was chosen for this study because of the relatively sharp clinical end-point obtainable. A consecutive series of patients was treated with aqueous penicillin G given intramuscularly at twelve-hour intervals. The patients were admitted to the public wards of the Johns Hopkins Hospital between October, 1947, and May, 1948. Only cases of clear-cut pneumococcal lobar pneumonia were included, selection being based upon a characteristic history, physical and x-ray evidence of pulmonary consolidation, fever, leukocytosis and the presence of typable pneumococci in the sputum, nasopharynx or blood. There were 82 such cases. All were not seen by us, the care of the patients being primarily the

responsibility of the resident staff. An effort was made to retain in the study all patients admitted with pneumococcal lobar pneumonia. However, because of misunderstandings, 3 patients were omitted from the series. They were only moderately ill and recovered uneventfully. Five patients were placed on intermittent intramuscular therapy after a short trial on the twelve-hour schedule. In 2 of these cases the regimen was altered because of the development of complications discussed below. In the remaining 3, discontinuance of the experimental dosage was considered in review to have been arbitrary, and the administration of 100,000 units of penicillin every two hours produced no dramatic alteration of the clinical course. All patients recovered. The total number receiving the trial dosage was therefore 79.

Cultures of the sputum, nasopharynx and blood were obtained before penicillin treatment was started. Most of the patients received a potassium salt of crystalline penicillin G of a single lot number, provided for these studies in 300,000-unit vials. The remainder were given the usual ward supply of penicillin, which varied somewhat as to degree of purity. The penicillin was given intramuscularly in distilled water. The initial dose was 300,000 units repeated at twelve-hour intervals until the temperature had remained normal for forty-eight hours, when 300,000 units was given at twenty-four-hour intervals for an additional forty-eight hours, unless there was some indication for more prolonged therapy. In 2 cases 600,000 units was given initially to severely ill patients.

No control series was established, the number of patients treated at this hospital each year making this impractical. However, there are available for comparison data on the patients with lobar pneumonia treated at this hospital with penicillin during the same period of 1945-1946 and 1946-1947. There were 69 patients in the 1945-1946 series. These were divided almost equally into three groups, receiving respectively 20,000, 40,000 and 80,000 units of aqueous penicillin intramuscularly at three-hour intervals. Fifty-eight patients were treated in 1946-1947 with penicillin in oil and beeswax. The majority of this group were given 300,000 units intramuscularly every twenty-four hours. A few initially received 300,000 units every twelve hours.

Comparative data for the three series regarding population sample, pneumococcal types and severity of disease are shown in Table 1. In general

the pneumonia was considered to be of average and equal severity in the three groups studied. No deaths or serious complications occurred in the 1945-1946 or 1946-1947 series. However, neither of these groups comprised all the patients admitted because of pneumonia during the years concerned, since a few of the most severely ill patients were given massive amounts of penicillin or a sulfonamide in addition. Death and complications

no superiority in the response of patients receiving frequent dosages of aqueous penicillin or repository penicillin as contrasted with the response of those receiving aqueous penicillin G at twelve-hour intervals. What minor differences there were favored the latter schedule.

Two deaths occurred in the 82 patients treated during 1947-1948. One happened three hours after admission in a patient with severe hyperthyroidism,

occurred in a few of these excluded patients. Therefore, the mortality and occurrence of complications in these two groups cannot be compared to those of the relatively consecutive 1947-1948 series. But it is valid to use these earlier groups as a basis of comparison of the rapidity of response to penicillin therapy.

### RESULTS

The response of the patients to the several regimens of penicillin is shown in Table 2 and expressed in terms of total febrile days, total days in bed and period of hospitalization. Within the limitations of this type of clinical study there was

auricular fibrillation and cardiac failure after a single injection of 900,000 units of aqueous penicillin. The other occurred seven hours after admission in a patient with a severe head injury who was given 100,000 units of aqueous penicillin intramuscularly at three-hour intervals. Two patients in this group developed complications of their infection. Pneumococcal meningitis appeared in one patient sixteen hours after admission. He had a pneumonia due to a pneumococcus Type 2 with bacteremia. The other complication appeared in a fifty-nine-year-old Negro known to have had chronic pulmonary disease for twelve years. He was admitted with pneumonia of the right upper and

middle lobes due to a Type 7 pneumococcus with bacteremia. Thirteen days after admission cavitation was noted in the right middle lobe. There is a reasonable possibility that both these complications had their inception before the institution of therapy. With the appearance of these complications, the patients were given massive doses of penicillin and sulfonamides. Recovery occurred in both cases.

Only a single patient in the 1947-1948 series developed a penicillin reaction. This followed the use of the highly purified penicillin G and consisted of fever and exfoliative dermatitis on the twelfth

circulating penicillin. Since therapeutic response was so satisfactory it appears questionable whether a constant blood level of penicillin is necessary in the treatment of pneumococcal pneumonia. The employment of repository forms such as penicillin in oil and beeswax or procaine penicillin, or the administration of aqueous penicillin at short intervals, is unnecessary in the therapy of lobar pneumonia. Whether infrequent dosage of penicillin in aqueous solution will be effective in the treatment of other infections has not been determined. The experimental work suggests that it would be effective. However, only careful clinical observation

day of therapy. No severe local reactions occurred. With aqueous "ward-stock" penicillin at three-hour intervals, the systemic reaction rate was 10 per cent, and with penicillin in oil and beeswax it was 19 per cent. An additional 25 per cent of patients had a local reaction to penicillin in oil and beeswax, characterized by pain, redness and edema at the site of injection.

## DISCUSSION

Penicillin G in aqueous solution given at twelve-hour intervals was found to be a highly effective means of treating pneumococcal lobar pneumonia. Death and complications each occurred in but 2.4 per cent of the 82 cases. In terms of the number of febrile days, the number of days in bed and the period of hospitalization, the administration of penicillin at twelve-hour intervals was at least as effective as the schedules designed to maintain a constant penicillin blood concentration.

A single dose of 300,000 units of aqueous penicillin G given intramuscularly maintains the concentration in the blood above 0.1 unit per cubic centimeter for only five or six hours,<sup>14</sup> so that for about half the time these patients had little if any

will demonstrate how universally this method of therapy may be safely applied.

It is quite likely that the amounts of penicillin G employed in this study were in excess of what is needed for adequate therapy of pneumococcal lobar pneumonia. A total dose of 90,000 to 300,000 units of aqueous penicillin will cure some patients with lobar pneumonia.<sup>1</sup> However, there seems to be little justification for determining the minimal effective dosage of penicillin in a disease with a potential mortality of 30 per cent. This position is supported by the infrequency of complications accompanying the use of fairly brisk dosage and by the lack of toxicity of pure penicillin G. It has been shown in streptococcal infections in mice that a large initial dose of penicillin G keeps the mice alive much longer than the same dose split into smaller fractions, even though the dose is too small to save any of the mice ultimately.<sup>5</sup> It seems wise to use similar large initial priming doses of penicillin G in the treatment of pneumococcal pneumonia and other infections. Such priming doses are an essential part of the successful use of the sulfonamides, and it is a curious circumstance that a similar loading device has not been carried over to the penicil-

lin treatment of infections In the use of slowly absorbed penicillin preparations such as penicillin in oil and beeswax and procaine penicillin or indeed when penicillin in aqueous solution is given in equal fractions at three-hour intervals, the advantage of a priming dose is lost

### SUMMARY AND CONCLUSION

Two hundred and six cases of pneumococcal lobar pneumonia treated with penicillin are reported In these cases 79 patients were treated with aqueous penicillin G given intramuscularly every twelve hours, 69 received aqueous penicillin intramuscularly every three hours, and 58 were given penicillin in oil and beeswax

The patients who were treated with 300,000 units of aqueous penicillin G intramuscularly every twelve hours fared as well as those on the usual schedules of administration

The intramuscular administration of 300,000 units of aqueous penicillin G every twelve hours is the treatment of choice for pneumococcal lobar pneumonia

We are indebted to Dr K K Chen, of Eli Lilly and Company, Indianapolis, Indiana, for a generous supply of the potassium salt of pure penicillin G

## THE USE OF TESTOSTERONE IN THE TREATMENT OF DEPRESSIONS\*

MARK D ALTSCHULE, M D,† AND KENNETH J TILLOTSON, M D.‡

BOSTON AND WAVERLEY, MASSACHUSETTS

SEX hormones and related substances have been used in the treatment of depressions for a number of years Although the use of estrogenic substances of various types has yielded disappointing results in deeply depressed women, the injection of testosterone has been known for a decade or more to cause remission in male patients with depressions, provided large doses are used Danziger and Blank<sup>1</sup> reviewed the earlier clinical literature bearing on this point, a more recent review by Danziger et al<sup>2</sup> is also available The rationale for the use of testosterone in the past has been that of replacement therapy in men past middle life However, the fact that small doses are ineffective should have suggested the inadequacy of this concept

Recent studies have shown that electroconvulsive therapy gives rise to effects resembling those caused by the action of some steroid hormones<sup>3-8</sup> The effects of electroshock therapy that resemble those occurring after the injection of steroid hor-

mones consist, briefly, in fall in plasma protein level, decrease in lymphocytes in the peripheral blood and reduction in eosinophil count, increased diuretic response to water and evidence of extracellular retention of water and sodium The administration of desoxycorticosterone and of progesterone in large doses having failed here to cause remission of mental symptoms, it was decided to use testosterone, all three of the hormones mentioned have the effect of causing salt and water retention, but only the last has an additional marked anabolic action The present report summarizes experience here to date

### MATERIAL AND METHODS

Thirty-one patients, ranging in age from thirty-one to seventy-four years, were given testosterone by injection They included patients with depressed phase of the manic-depressive psychosis, with involutional psychoses with depression, with reactive depressions and, in 1 case, schizophrenia with a strong depressive component Only 3 were women, 2 of them having involutional psychoses and the third a manic-depressive psychosis in the depressed phase

\*From the Clinical Services and the Laboratories of Clinical Physiology, McLean Hospital Waverley Massachusetts, and the Departments of Medicine and Psychiatry Harvard Medical School

†Assistant professor of medicine, Harvard Medical School director of research in clinical physiology McLean Hospital

‡Formerly, associate in psychiatry Harvard Medical School formerly, psychiatrist-in-chief McLean Hospital

Testosterone was given intramuscularly in doses of 50 mg daily for two or three weeks, in most cases it was given in two doses of 25 mg each day. In 1 case the material was given for six weeks, discontinued for a month and given again for a month. After discharge some of the patients were given methyl-testosterone orally, 30 mg per day. Seven of the patients received electroshock therapy at approximately the same time as the injection of the hormone, 7 had had shock therapy previously, and 6 were given it subsequently.

## OBSERVATIONS

### Clinical Results

Of the 7 patients, all men, given testosterone at approximately the same time as shock therapy, all improved and were discharged.

In the 17 patients who had not had shock therapy before receiving testosterone, the following effects were noted: improved (discharged), 11 (10 men, 1 woman), discontinued, 2 men, and not improved, 4 men.

Of the 4 men not improved by injection of testosterone, 3 subsequently were given electroshock therapy. All 3 improved, 1 after six treatments in the course of a month, 1 after four treatments a week apart, and 1 after thirty-two shocks given over a period of several months.

Seven patients were given testosterone during relapse after improvement with electroconvulsive therapy, with the following results: 3 men given testosterone one month after relapse were improved (discharged), neither of 2 women given testosterone one month after relapse improved, 1 man given testosterone five months after relapse improved (discharged), and 1 man given testosterone twelve months after relapse showed no improvement.

In 2 patients in this group who recovered after getting testosterone, relapse occurred after the hormone had been discontinued. Brief abstracts of these cases are as follows:

**CASE 1.** A 39-year-old man with a reactive depression was first seen in August, 1946. After five treatments of electroshock, given between December 10 and 20, he improved and gained 8 pounds. Later in that month he suffered a relapse. Eight additional electroshock treatments were given from January 1 to 17, 1947, with improvement and another gain of 8 pounds in weight. Another relapse occurred, and the patient was therefore given 25 mg of testosterone twice a day from February 8 to 21. He improved, gained 6 pounds and was discharged. A third relapse occurred in May.

**CASE 2.** A 54-year-old man with a manic-depressive (depressed) psychosis was seen in May, 1946. After six electroshock treatments in July he was improved, but during that month he relapsed. From January 17 to 31, 1947, seven electroshock treatments were given, with improvement and a gain of 14 pounds in weight. Another relapse occurred in February, and 25 mg of testosterone was given twice a day from March 4 to 26. The patient improved and gained 15 pounds, but suffered a further relapse during the following month. In May, improvement and a gain of 9 pounds in weight followed fourteen electroshock treatments.

All 3 patients in this group who did not respond to testosterone were subsequently given shock therapy. The 2 women improved after twelve shocks given over a period of five weeks, they soon relapsed, however. Still another course of shock therapy was then given to 1 of these patients, who died during the treatment, with massive hemorrhage of an adrenal gland. The man in this group improved after six shocks and maintained his improvement for two months before relapsing.

### Side Reactions

Two patients could not receive the full course of treatment with testosterone because of the development of edema, tachycardia and severe dyspnea, both were known to have had mild congestive failure previously. Digitalis and ammonium chloride did not influence these symptoms, which remained markedly discomforting for approximately a week. Two other patients exhibited mild edema and shortness of breath, they had no evidence of heart disease.

Two patients exhibited gynecomastia during the course of treatment, one was a man of forty-four who many years previously had had a testicle removed for tumor, and the other was a man of sixty-three with no unusual previous findings in history or physical examination.

The women showed heavy overgrowth of facial hair.

## Discussion

The earlier work with testosterone<sup>1, 2</sup> involved the use of the hormone as a form of replacement therapy in men with involutional melancholia. Some authors<sup>1, 2</sup> gave as many as six injections, each of 25 mg of the hormone, each week for more than twelve weeks. In the present study the rationale of treatment was different in that the hormone was used as a substance with marked anabolic effects and not as a specific sex hormone.

The effect of testosterone is largely or entirely on the affective disorder, paranoid or other serious disturbances in thinking were not changed, and neurotic manifestations were influenced but little. The disappearance of depression, confusion and retardation, however, was definite.

Analysis of the clinical results is difficult. The 7 patients who received electroconvulsive therapy at approximately the same time as the injections of testosterone afford no data for judging the value of the latter. These patients were given testosterone when the course of shock therapy was interrupted by fractures or because the clinical staff believed that the patients' histories raised the possibility of early relapse after shock. In the 11 patients in whom improvement occurred when they were given testosterone not in relation to shock therapy, it is likewise difficult to evaluate the role of the hormone.

The natural history of depressions includes high rates of remission irrespective of therapy, the patients treated here were all receiving psychotherapy during the period of administration of testosterone, and all but 1 were hospitalized. Accordingly, the role of testosterone in relation to clinical improvement cannot be stated with certainty in spite of the fact that individual patients appeared to show no evidence of improvement until after the drug was started. The failures in this group are, however, of interest. They include 2 patients who could not receive the full course of therapy because of aggravation of the manifestations of congestive failure, 4 others who received the full course of injections did not respond, and 3 were then given shock therapy. One improved after thirty-two shocks given over a period of several months, and the other 2 improved after short courses of shock therapy. The last 2 of these patients must be regarded as definite cases of failure of testosterone therapy, but the first patient who received testosterone for only two weeks and then shock therapy for several months need not be.

The results in the patients who received testosterone after relapse following improvement due to electroshock therapy show that the effects of testosterone and of electroshock are interchangeable, at least in some cases. The only failure in the men was a patient who received testosterone a year after receiving shock therapy, he subsequently improved again with shock therapy. Possibly a longer course of testosterone should have been given in his case if one can judge by the results in the man who was given testosterone five months after shock, this patient required six weeks of testosterone for striking benefit to be obtained, although he showed some improvement after two weeks. The 2 women who failed to respond to testosterone given a month after relapse following improvement with shock therapy received the drug for three weeks, both required five weeks of shock therapy for temporary remission of their depressions.

It is possible, judging from the earlier work cited above,<sup>1,2</sup> that longer courses of treatment with testosterone would have helped some of the patients who showed no improvement in the present study. Long courses have not been employed here as a rule because of the untoward cosmetic effects in women, and because of the more rapid improvement caused by electroshock therapy in patients who might be suicidal, the expense of unnecessary prolongation of hospitalization was also taken into account.

The untoward effects of testosterone therapy—that is, hirsutism in women and excessive salt re-

tention in patients with myocardial insufficiency—were expected. The occasional occurrence of gynecomastia resembles that reported by McCullagh and Rossmiller<sup>9</sup> in patients receiving androgen therapy.

The fact that the effects of testosterone and of electroshock therapy are interchangeable supports the concept that the physiologic changes indicative of increased production of some steroid hormones seen during shock therapy are causally related to remission of mental disease caused by the latter. Since the steroid hormone effects involved are not those of salt and water retention but seem to be an anabolic reaction, it is possible that the effects of electroshock therapy are primarily reparative and, if at all destructive, only incidentally so. This concept may explain the fact that affective disorders occurring during the course of such destructive processes as general paresis and multiple sclerosis are benefited by shock therapy.

#### SUMMARY AND CONCLUSIONS

The administration of testosterone in large doses is followed by remission of mental symptoms in some patients with all types of depression. The hormone acts apparently not as a specific sex hormone but as a substance with strong anabolic effects. In some patients it can be shown that the effects of electroshock and of testosterone are interchangeable, a phenomenon that suggests that the beneficial effects of convulsant therapy are the results of increased production of some steroid hormones. It is not unlikely that the favorable effects of electroshock therapy are reparative and not destructive.

## POLLEN SENSITIVITY IN 100 ASTHMATIC CHILDREN

LEWIS WEBB HILL, M D \*

BOSTON

IT IS well known that pollen sensitivity is common in asthmatic children. The full importance of this, however, is not generally appreciated and in most textbooks and other discussions of asthma in childhood more emphasis is given to such allergens as house dust, animal danders and foods than to pollens. In my experience pollen sensitization and the common infectious cold are the two most frequent causes of asthmatic attacks in children and the number of cases that are helped by removal of a cat, a mattress or some food is small indeed when compared with those in which the attacks are precipitated by pollen or infectious colds.

In an allergy practice or clinic devoted to adults, patients with uncomplicated hay fever predominate. With children this is not so, and of 100 consecutive cases of respiratory allergy from my office files there were 80 cases of asthma and only 20 of hay fever. A high proportion of children who begin with hay fever have pollen asthma after a few seasons.

The pollen season in New England lasts about six months (from April 15 to October 10), and in children the majority of attacks of asthma occurring during this period are due to pollen.

Of 100 asthmatic patients between the ages of three and twelve years tabulated in alphabetic order from my office records, 70 gave positive scratch tests to one or more pollens. In contrast to positive tests with foods (about 20 per cent etiologic), a positive test with pollen as a rule indicates clinical sensitivity. Among the 70 children who gave positive reactions to pollen there were 225† positive tests. Of these, approximately 90 per cent were thought to be of clinical significance (Table 1).

## INTRACUTANEOUS TESTS

As a rule, skin sensitivity to pollen in children is not of such high degree as that in adults. The younger the child and the shorter time he has had symptoms the more likely is this to be so. The more delicate intracutaneous test often reveals sensitization when the scratch test will not. It is my practice first to do scratch tests with pollens as a routine on all asthmatic patients, which are followed by intracutaneous tests if the child has symptoms during the season of any pollen and fails to react to it by scratch test. In children the scratch test can by no means be relied upon to demonstrate pollen sensitization.

Intracutaneous tests were done on 20 of the 30 children who failed to give a positive scratch test to any pollen. There were positive reactions to one or more pollens in 14. Of the 100 children under discussion, therefore, 84 gave positive tests, either scratch or intracutaneous, to pollen. All the positive intracutaneous tests were presumably of clinical significance, since they were done only on a

TABLE 1 Positive Scratch Tests to Pollens in 100 Asthmatic Children

Birch	26
Maple	18
Ash	3
Elm	5
Oak	10
English plantain	4
Grass pollen	40
Ragweed	45

selected group, whose histories suggested clinical sensitivity.

## TREE POLLEN

In New England birch and oak are the most important trees as far as asthma is concerned. Maple pollen gives a good many positive reactions, but is relatively unimportant as a cause of asthma, for it is heavy and sticky and is therefore not disseminated as readily as birch and oak pollen.

## GRASS POLLEN

Twenty-two patients reacted to all the four grass pollens employed in scratch tests, 18 reacted to one or more, but not to all. There were 28 patients who gave positive intracutaneous but negative scratch tests to grass pollen. There were therefore 68 out of 100 who reacted to grass pollen. Positive scratch tests were about equally divided between the four grasses, as follows: timothy, 30, red top, 27, June grass, 28, and orchard grass 29.

## RAGWEED

In 28 patients there was a positive intracutaneous test to ragweed with a negative scratch test. There were therefore 73 out of the 100 children who reacted to this pollen.

## ASSOCIATED SENSITIZATIONS

There was no child who reacted to pollen who did not also react to other environmental allergens. House dust, cat hair and mold (alternaria or hor-mo-dendrum) were the most common, with 65 positive reactions to dust, 39 to cat hair, and 38 to

\*Associate in pediatrics, Harvard Medical School, visiting physician, Child in a Hospital.

†The discrepancy between this figure and the sum total of the figures given in the table is because tests were done with four different grass pollens and usually more than one gave positive tests.

The natural history of depressions includes high rates of remission irrespective of therapy, the patients treated here were all receiving psychotherapy during the period of administration of testosterone, and all but 1 were hospitalized. Accordingly, the role of testosterone in relation to clinical improvement cannot be stated with certainty in spite of the fact that individual patients appeared to show no evidence of improvement until after the drug was started. The failures in this group are, however, of interest. They include 2 patients who could not receive the full course of therapy because of aggravation of the manifestations of congestive failure, 4 others who received the full course of injections did not respond, and 3 were then given shock therapy. One improved after thirty-two shocks given over a period of several months, and the other 2 improved after short courses of shock therapy. The last 2 of these patients must be regarded as definite cases of failure of testosterone therapy, but the first patient who received testosterone for only two weeks and then shock therapy for several months need not be.

The results in the patients who received testosterone after relapse following improvement due to electroshock therapy show that the effects of testosterone and of electroshock are interchangeable, at least in some cases. The only failure in the men was a patient who received testosterone a year after receiving shock therapy, he subsequently improved again with shock therapy. Possibly a longer course of testosterone should have been given in his case if one can judge by the results in the man who was given testosterone five months after shock, this patient required six weeks of testosterone for striking benefit to be obtained, although he showed some improvement after two weeks. The 2 women who failed to respond to testosterone given a month after relapse following improvement with shock therapy received the drug for three weeks, both required five weeks of shock therapy for temporary remission of their depressions.

It is possible, judging from the earlier work cited above,<sup>1,2</sup> that longer courses of treatment with testosterone would have helped some of the patients who showed no improvement in the present study. Long courses have not been employed here as a rule because of the untoward cosmetic effects in women, and because of the more rapid improvement caused by electroshock therapy in patients who might be suicidal, the expense of unnecessary prolongation of hospitalization was also taken into account.

The untoward effects of testosterone therapy—that is, hirsutism in women and excessive salt re-

tention in patients with myocardial insufficiency—were expected. The occasional occurrence of gynecomastia resembles that reported by McCullagh and Rossmiller<sup>9</sup> in patients receiving androgen therapy.

The fact that the effects of testosterone and of electroshock therapy are interchangeable supports the concept that the physiologic changes indicative of increased production of some steroid hormones seen during shock therapy are causally related to remission of mental disease caused by the latter. Since the steroid hormone effects involved are not those of salt and water retention but seem to be an anabolic reaction, it is possible that the effects of electroshock therapy are primarily reparative and, if at all destructive, only incidentally so. This concept may explain the fact that affective disorders occurring during the course of such destructive processes as general paresis and multiple sclerosis are benefited by shock therapy.

#### SUMMARY AND CONCLUSIONS

The administration of testosterone in large doses is followed by remission of mental symptoms in some patients with all types of depression. The hormone acts apparently not as a specific sex hormone but as a substance with strong anabolic effects. In some patients it can be shown that the effects of electroshock and of testosterone are interchangeable, a phenomenon that suggests that the beneficial effects of convulsant therapy are the results of increased production of some steroid hormones. It is not unlikely that the favorable effects of electroshock therapy are reparative and not destructive.

BAL was ineffective in preventing *in vitro* hemolysis of red blood cells by arsine, whereas a related compound, BAL ethyl ether (2, 3-dimercaptopropylether), worked very well. These findings were borne out in arsine inhalation poisoning in rabbits and cats, in which BAL ethyl ether given immediately after exposure was found to be an effective agent, whereas BAL was useless.<sup>46, 47</sup> Because of its great toxicity, it seems unlikely that BAL ethyl ether will be of value in the treatment of arsine poisoning among human beings. Leivy<sup>48</sup> found that another compound, ethane-1,2-dithiol, given intraperitoneally decreased the toxicity of arsine for mice. This compound was effective when given as long as three to four hours after exposure to arsine.

Hughes,<sup>49</sup> studying the effects of lewisite on the rabbit eye, found that it produced rapid necrosis of the cornea and conjunctiva, and that arsenic liberated from the lewisite rapidly penetrated into the chambers of the eye. BAL, in a 5 per cent ointment, proved to be a satisfactory antidote because it not only detoxified the lewisite at the surface of the eye but also rapidly penetrated the tissues of the eye to unite with the arsenic there. Because of the rapid action of lewisite, the ointment had to be applied within two minutes of the lewisite to protect the eye completely; if applied after thirty minutes, permanent damage from the lewisite always occurred. BAL itself in ointment concentrations greater than 5 per cent was found to produce a transient opacification of the superficial layers of the cornea.

#### *Clinical Uses*

After it became apparent that BAL was effective against arsenic poisoning in animals, it was tried in various clinics in the treatment of accidental arsenic poisoning and the undesirable side effects occurring in arsenotherapy.

BAL has been used extensively in the treatment of arsenical dermatitis with good results.<sup>30, 50, 51</sup> In severe cases, edema, fever and pruritus disappear or greatly decrease in twenty-four hours, and complete recovery may occur within two weeks. However, some patients respond only partially, or may relapse and require another course of BAL, whereas others may show no improvement at all. Occasionally, as has been noted, abscesses, which are probably due to secondary infection, occur at the sites of intramuscular injection. Although injections of BAL are beneficial in dermatitis, they are not so effective as intramuscular injections and may cause skin sensitization to BAL.

Eagle and Magnuson<sup>30</sup> have reported the results of BAL therapy in 55 cases of arsenical encephalitis, usually a lethal complication of arsenotherapy. Only 11 patients died, and in 5 of these BAL therapy was not started until nine to seventy-two hours after the onset of encephalitis. These workers

likewise studied the value of BAL in the treatment of 16 patients with so-called post-arsenical jaundice. Only 5 of the 16 patients recovered within ten days of initiation of therapy. The results in this small series of cases suggest that BAL is not very effective in postarsenical hepatitis, but it must be remembered that some authorities consider this condition to be an infection rather than a toxic manifestation of arsenic.

BAL has been of value in some blood dyscrasias associated with arsenotherapy. Eagle and Magnuson<sup>30</sup> reported the failure of BAL to affect the course of 3 cases of aplastic anemia and 1 case of agranulocytosis with thrombocytopenia occurring in persons undergoing arsenotherapy. On the other hand, 10 cases of agranulocytosis responded promptly to BAL—all showing an increase in granulocytes by the second day and a normal count by the seventh day. Holley<sup>52</sup> reported equally good results in 12 cases of arsenical agranulocytosis treated with BAL. Schrumph<sup>53</sup> reported a favorable result following BAL in a patient with thrombocytopenic hemorrhages associated with neoarsphenamine therapy. In 11 days there was an increase in the platelet count from 2500 to 280,000.

BAL has been used in 4 patients who had received massive doses of mapharsen by error.<sup>30</sup> Three patients had received doses of between 400 and 600 mg of mapharsen each and made uneventful recoveries after the administration of BAL. The fourth patient was given 1200 mg of mapharsen and died after inadequate BAL treatment in spite of an initially favorable response.

Several cases of optic complications following arsenotherapy have been treated by BAL. Eagle and Magnuson<sup>30</sup> reported a good response in 3 of 6 patients with visual impairment associated with triparsamide therapy. Friedenber<sup>54</sup> observed that a tabetic patient in whom a decrease in visual fields followed triparsamide therapy had a return of vision after the administration of BAL.

Woody and Kometani<sup>55</sup> have reported on the use of BAL in a large group of infants and children. They treated 42 infants and children who had ingested arsenic-containing substances. Of these, 22 had taken potentially lethal amounts of arsenic. There were no deaths in this series, and in all cases signs and symptoms of arsenic poisoning disappeared within twelve hours of the initiation of BAL therapy.

#### MERCURY

It has been shown that BAL can both prevent the inhibitory effect of mercuric chloride on a brain brei preparation, and reactivate the enzyme succinoxidase after mercury inactivation.<sup>55, 56</sup>

Studies with BAL, BAL glucoside and the monothiol thiosorbitol<sup>44</sup> demonstrated that all three could protect rabbits against acute mercury poisoning if therapy was begun properly. Quantitative evalu-

mold I doubt whether uncomplicated pollen allergy exists in asthmatic children, and it is uncommon in children with hay fever. This is a very different situation from that in adults, among whom uncomplicated pollen allergy in hay fever is common.

#### SUMMARY AND CONCLUSIONS

In a series of 100 asthmatic children between the ages of three and twelve years, there were positive skin reactions to one or more pollens in 84.

Approximately 90 per cent of these reactions were of clinical significance.

The scratch test, particularly in children, is frequently not delicate enough to demonstrate pollen sensitization.

Asthmatic children who are sensitized to pollen are always sensitized to other environmental allergens as well.

The importance of pollen sensitization in the asthma of children is not sufficiently appreciated. In New England, pollen is the most important factor contributing to asthma in children during the spring, summer and early fall—approximately six months of the year.

## MEDICAL PROGRESS

### BAL (Concluded)\*

RAYMOND V. RANDALL, M.D., AND ALBERT O. SEELER, M.D.†

BOSTON

#### ARSENIC

Stocken and Thompson<sup>39</sup> found that the topical application of BAL to lewisite burns was followed by an increase in the urinary excretion of arsenic. These authors then demonstrated that parenteral administration of BAL saved rats poisoned by the application of lethal amounts of lewisite to the body surface. Harrison and his co-workers<sup>40</sup> concluded from their experiments on dogs that the most effective way to treat extensive lewisite burns was to use BAL ointment to combat the local skin effects of lewisite, and, at the same time, to use the compound parenterally to combat the effects of the absorbed arsenic.

Eagle et al.<sup>4</sup> have shown that BAL applied to the skin or given parenterally was effective in the treatment of acute and subacute arsenic poisoning in various animals. In animals so treated, there was a striking increase in the rate of urinary arsenic excretion with the peak of excretion coming two to four hours after the administration of BAL. In conjunction with these findings, Riker and Rosenfield,<sup>41</sup> in studies on the effect of BAL on mapharsen-poisoned cats, found that it increased the concentration of arsenic in the plasma. After the injection of BAL, a high level of plasma arsenic was reached within one hour and a peak at two hours. These results were considered to be in accord with the concept that BAL effects a withdrawal of arsenic from the tissues.

Peters and Stocken<sup>42</sup> prepared a complex from mapharsen and BAL and found it to be more toxic than either BAL or arsenic alone. However, when this complex was injected together with one mole excess of BAL, it was only one fifth as toxic as arsenic alone. The authors suggested that this phenomenon could be explained by the dissociation of the mapharsen-BAL complex to release arsenic in areas where it could cause the maximum toxic effects. However, when excess BAL was present, the extent of dissociation and, consequently, the toxicity of the complex were decreased. Another explanation may be that one mole of arsenic can unite with one or two moles of BAL to form complexes of greatly different properties, as cadmium and mercury do.<sup>43-44</sup> Even more paradoxical are the findings of Koppanyi and Sperling,<sup>45</sup> who gave BAL to rabbits that had received nonlethal doses of sodium arsenite, and found that the animals developed intense central-nervous-system stimulation. The same amounts of arsenite or BAL alone did not produce symptoms, and massive doses of a preformed arsenite-BAL complex were likewise nontoxic. Similar effects were not noted with arsenates or organic arsenicals. On the basis of these experiments, the authors warned that persons poisoned by arsenites (such as Fowler's solution) might conceivably develop undesirable side effects if treated with BAL.

Several investigators have studied the effect of BAL and related compounds on arsine poisoning. Inhalation of this extremely toxic gas may cause intense hemolysis of the red blood cells, with subsequent hemoglobin nephrosis. It is also an inhibitor of tissue respiration. Kensler et al.<sup>46</sup> found that

\*From the Department of Industrial Hygiene, Harvard School of Public Health.

This study was aided by a grant from the Medical Advisory Committee of the American Petroleum Institute.

†Assistant professor of industrial medicine, Harvard School of Public Health.

matitis, of possible benefit in 2 cases of dermatitis and of no value in a case of dermatitis of moderately short duration

Lockie and his co-workers<sup>72</sup> found BAL to be strikingly effective in the treatment of 2 patients with blood dyscrasias following chemotherapy. A patient with thrombocytopenia, bleeding gums and coma from a possible subarachnoid hemorrhage responded to BAL within several days and had a concurrent increase in platelets from 15,000 to 120,000. The other patient had agranulocytosis, and within seventy-two hours after initiation of BAL therapy the granulocytes increased from zero to 17 per cent, and by the seventh day they had increased to 45 per cent.

### LEAD

Although BAL can reverse the lead inhibition of the sulfhydryl-containing enzyme, succinoxidase,<sup>56</sup> and can increase the urinary output of lead, there is no satisfactory evidence that it is of value in the treatment of lead poisoning.

### Animal Studies

Braun et al.<sup>73</sup> concluded that BAL was ineffective in both acute and chronic experimental lead poisoning. They gave BAL to rabbits poisoned by a single large dose of lead nitrate and to others poisoned by multiple small doses of lead nitrate, and in each case the mortality in animals treated with BAL was greater than that in animals receiving lead nitrate alone. This suggested that BAL had an additive effect. Germuth and Eagle<sup>74</sup> likewise found that BAL failed to protect rabbits against acute or chronic lead poisoning, and in one group of animals found that BAL hastened the onset of death. BAL did cause a marked increase in the urinary excretion of lead, but this response decreased with each subsequent injection. The period of increased urinary excretion of lead began immediately after the injection of BAL, reached a peak in about two hours and then returned to the preinjection level in three or four hours. A preformed lead-BAL complex was injected into rabbits and found to be almost as toxic as lead acetate, despite the fact that it had a low dissociation constant. These authors concluded that BAL can release some lead from its combination with the tissues and force it to be excreted in the urine, but that the amount of lead thus eliminated is too small to effect the eventual outcome of the poisoning. In addition, they pointed out the possibility that a toxic lead-BAL complex could be formed *in vivo*, and postulated that this could account for the additive effects of BAL in experimental lead poisoning.

Chiodi and Sammartino<sup>75</sup> were able to increase the weight of rat kidneys by the daily administration of lead acetate. This increase in kidney weight did not appear when BAL was given concurrently with the lead acetate.

### Human Poisoning

Telfer<sup>76</sup> studied the effect of BAL on a patient suspected of having lead poisoning. Although prior to BAL therapy the patient's urinary output of lead was within normal limits, the urinary lead excretion increased after therapy.

Ryder and his co-workers<sup>77</sup> studied the effects of a single intramuscular dose of BAL on the lead concentration in the blood and urine of men who had been exposed to lead. After BAL the concentration of lead in the whole blood started to fall within seven and a half minutes, reached a minimum in eight hours and returned to the original level in twenty-four hours. Simultaneously, there was an increase in the urinary output of lead. This effect could be produced repeatedly by subsequent injections of BAL. In spite of the reduction in the whole-blood lead concentration by BAL, the plasma levels were unaffected, indicating that large amounts of lead were released from the erythrocytes and rapidly removed from the blood stream. Although BAL produced these findings, which are of interest, it failed to shorten the clinical course of lead intoxication.

### CADMIUM

Cadmium is a sulfhydryl enzyme inhibitor, and its inhibitory effect can be reversed by BAL and other dithiols. The monothiol glutathione can bring about reactivation also, but only when given in large amounts.<sup>56</sup>

Lethal doses of cadmium given parenterally cause intense gastrointestinal activity, muscular weakness, prostration, severe dyspnea and death within twenty-four hours. Gilman and his co-workers<sup>78</sup> found that BAL could prevent this acute death from taking place in rabbits, if it were given just prior to the cadmium, but a delayed death from renal damage invariably occurred. Paradoxically, when BAL was given thirty minutes after a lethal dose of cadmium, only 50 per cent of the animals died, although, again, all deaths were the result of renal failure. More effective than BAL was BAL glucoside, which protected the majority of animals from the lethal effects of cadmium. Thiosorbitol and thioxylate, both monothiols, saved only a limited number of animals from cadmium deaths. Strangely enough, all the fatal results in the monothiol-treated animals were from typical acute cadmium poisoning rather than from renal damage as in animals dying after BAL and BAL glucoside therapy. The authors postulated that the renal deaths following BAL therapy could be explained by the assumption that BAL and cadmium form a relatively unstable complex. Hence, although BAL diverts the cadmium away from tissues usually affected by this metal, it carries it to the kidney, where enough cadmium dissociates to cause severe renal damage. The decrease in renal damage seen

ation of the protective activity of these compounds showed that the dithiols were far superior to thiosorbitol. BAL glucoside proved to be more active than BAL itself. Rabbits receiving inadequate doses of the thiol compounds died of renal failure. It is interesting to note that although BAL and BAL glucoside can also prevent the development of fatal renal damage in dogs after large intravenous doses of mercuric chloride, some of the animals succumbed to acute pulmonary edema. When mercuric chloride was given orally, BAL and BAL glucoside were also effective in preventing renal deaths, but some of the animals died of a hemorrhagic gastroenteritis.

Because of the extensive use of sodium formaldehyde sulfoxylate as an antidote for mercury poisoning, Stocken<sup>67</sup> compared the effectiveness of this compound with that of BAL. He found that BAL fully protected rats from lethal doses of mercuric chloride, whereas sodium formaldehyde sulfoxylate proved ineffective under similar conditions.

### *Human Poisoning*

Longcope and Luetscher<sup>68</sup> have used BAL extensively in the treatment of acute poisoning in man after the ingestion of mercury bichloride. They reported that of 42 patients suffering from acute mercury poisoning in whom BAL was used, only 2 died. These 2 patients were in a group of 5 cases in which BAL was not started until six to forty-two hours after the ingestion of mercury. Not one of 37 patients receiving BAL within four hours died, regardless of the severity of symptoms or the amount of mercury taken. This stresses the importance of instituting BAL therapy at the earliest possible moment. However, one should not overlook the value of general supportive measures such as intravenous fluids and transfusions. The schedule of BAL treatment for mercury poisoning recommended by the Council on Pharmacy and Chemistry of the American Medical Association (as listed below under dosage schedules) is based on the experience of these authors.

### *Effects on Mercurial Diuretics*

BAL can prevent the occurrence of convulsions and cardiac arrhythmias produced in experimental animals by the administration of mercurial diuretics. It can also prevent the characteristic diuresis produced by these drugs<sup>69-71</sup>. In contrast to BAL, which inhibits both the toxic and the diuretic effects, the monothiols cysteine and glutathione can protect the hearts of animals against toxic effects of the mercurial diuretic mersalyl without abolishing its diuretic effect<sup>65</sup>. Further evidence that monothiols reduce the toxicity of mercurials is supplied by the work of Lehman,<sup>66</sup> who synthesized a diuretic containing thioglycolic acid that proved to be only one-fourth as toxic as one-sixth as toxic as comparably effective mer-

curial diuretics. These findings suggest the possibility of using certain monothiols either in chemical combination or by simultaneous administration to abolish the undesirable effects of mercurials without impairing their diuretic action. However, each mercurial compound must be thoroughly investigated before clinical use in such a manner, because Cohen<sup>67</sup> has reported that a number of alkyl mercuric thioglycollates can produce severe central-nervous-system effects.

### *Acrodynia*

Because mercury has recently been suspected of having a causal relation to acrodynia, Bivings and Lewis<sup>68</sup> gave a twelve-day course of BAL to an infant in whom the diagnosis of acrodynia had been made. It is of interest that this infant had been given twelve doses of calomel and rhubarb a number of weeks before the onset of the signs and symptoms that led to the diagnosis of acrodynia. The urine showed a mercury concentration of 100 microgm per 100 cc before the initiation of BAL therapy. Eight days after the last dose of BAL, the urine was found to be free of mercury, and a week or two later all signs and symptoms of acrodynia had disappeared.

### *GOLD*

Thompson and Whittaker<sup>65</sup> found that BAL can protect the brain pyruvate oxidase system from the toxic effects of gold. However, the striking difference in effectiveness between dithiols and monothiols noted in arsenic poisoning was not found; glutathione gave the same degree of protection against gold inhibition as BAL did.

Gold therapy is used extensively in rheumatoid arthritis although it is a potentially toxic agent capable of causing pruritus, dermatitis, stomatitis, agranulocytosis, thrombocytopenia and other disorders. BAL has been used in several clinics to treat these complications of gold therapy. Ragan and Boots<sup>69</sup> reported a series of 5 patients with gold dermatitis who were treated with BAL. In 4 patients there was prompt subsidence of pruritus, and the rash disappeared within one month of BAL treatment. No change took place in the fifth patient's condition. All patients showed an increase in excretion of urinary gold, concurrent with the administration of BAL. Four of the patients had a recurrence of arthritic symptoms shortly after the BAL treatment, offering some support to the contention that chrysotherapy has only a temporary effect on rheumatoid arthritis. Cohen et al<sup>70</sup> found that BAL caused prompt recovery in 5 cases of gold dermatitis of short duration. The authors attribute these excellent results, in part, to the fact that BAL therapy was instituted early in each case. Margolis and Caplan<sup>71</sup> state that in their experience BAL was of marked benefit in a case of severe stomatitis and a case of dermatitis and sto-

matitis, of possible benefit in 2 cases of dermatitis and of no value in a case of dermatitis of moderately short duration

Lockie and his co-workers<sup>22</sup> found BAL to be strikingly effective in the treatment of 2 patients with blood dyscrasias following chrysotherapy. A patient with thrombocytopenia, bleeding gums and coma from a possible subarachnoid hemorrhage responded to BAL within several days and had a concurrent increase in platelets from 15 000 to 120 000. The other patient had agranulocytosis and within seventy-two hours after initiation of BAL therapy the granulocytes increased from zero to 17 per cent, and by the seventh day they had increased to 45 per cent.

### LEAD

Although BAL can reverse the lead inhibition of the sulfhydryl-containing enzyme, succinoxidase<sup>23</sup> and can increase the urinary output of lead, there is no satisfactory evidence that it is of value in the treatment of lead poisoning.

### Animal Studies

Braun et al.<sup>24</sup> concluded that BAL was ineffective in both acute and chronic experimental lead poisoning. They gave BAL to rabbits poisoned by a single large dose of lead nitrate and to others poisoned by multiple small doses of lead nitrate, and in each case the mortality in animals treated with BAL was greater than that in animals receiving lead nitrate alone. This suggested that BAL had an additive effect. Germuth and Eagle<sup>25</sup> likewise found that BAL failed to protect rabbits against acute or chronic lead poisoning and in one group of animals found that BAL hastened the onset of death. BAL did cause a marked increase in the urinary excretion of lead but this response decreased with each subsequent injection. The period of increased urinary excretion of lead began immediately after the injection of BAL, reached a peak in about two hours and then returned to the preinjection level in three or four hours. A preformed lead-BAL complex was injected into rabbits and found to be almost as toxic as lead acetate despite the fact that it had a low dissociation constant. These authors concluded that BAL can release some lead from its combination with the tissues and force it to be excreted in the urine but that the amount of lead thus eliminated is too small to effect the eventual outcome of the poisoning. In addition they pointed out the possibility that a toxic lead-BAL complex could be formed *in vivo* and postulated that this could account for the additive effects of BAL in experimental lead poisoning.

Chiodi and Sammartino<sup>26</sup> were able to increase the weight of rat kidneys by the daily administration of lead acetate. This increase in kidney weight did not appear when BAL was given concurrently with the lead acetate.

### Human Poisoning

Telfer<sup>27</sup> studied the effect of BAL on a patient suspected of having lead poisoning. Although prior to BAL therapy the patient's urinary output of lead was within normal limits, the urinary lead excretion increased after therapy.

Ryder and his co-workers<sup>28</sup> studied the effects of a single intramuscular dose of BAL on the lead concentration in the blood and urine of men who had been exposed to lead. After BAL the concentration of lead in the whole blood started to fall within seven and a half minutes, reached a minimum in eight hours and returned to the original level in twenty-four hours. Simultaneously, there was an increase in the urinary output of lead. This effect could be produced repeatedly by subsequent injections of BAL. In spite of the reduction in the whole-blood lead concentration by BAL, the plasma levels were unaffected, indicating that large amounts of lead were released from the erythrocytes and rapidly removed from the blood stream. Although BAL produced these findings, which are of interest, it failed to shorten the clinical course of lead intoxication.

### CADMIUM

Cadmium is a sulfhydryl enzyme inhibitor, and its inhibitory effect can be reversed by BAL and other dithiols. The monothiol glutathione can bring about reactivation also but only when given in large amounts.<sup>29</sup>

Lethal doses of cadmium given parenterally cause intense gastrointestinal activity, muscular weakness, prostration, severe dyspnea and death within twenty-four hours. Gilman and his co-workers<sup>30</sup> found that BAL could prevent this acute death from taking place in rabbits if it were given just prior to the cadmium but a delayed death from renal damage invariably occurred. Paradoxically, when BAL was given thirty minutes after a lethal dose of cadmium, only 50 per cent of the animals died, although again, all deaths were the result of renal failure. More effective than BAL was BAL glucoside, which protected the majority of animals from the lethal effects of cadmium. Thiosorbitol and thioxylate, both monothiols, saved only a limited number of animals from cadmium deaths. Strangely enough, all the fatal results in the monothiol-treated animals were from typical acute cadmium poisoning rather than from renal damage as in animals dying after BAL and BAL glucoside therapy. The authors postulated that the renal deaths following BAL therapy could be explained by the assumption that BAL and cadmium form a relatively unstable complex. Hence, although BAL diverts the cadmium away from tissues usually affected by this metal, it carries it to the kidney, where enough cadmium dissociates to cause severe renal damage. The decrease in renal damage seen

when BAL is given thirty minutes after the administration of cadmium is explained by the supposition that some of the cadmium becomes irreversibly fixed in the tissues, and thus a smaller amount eventually reaches the kidneys

The same authors found that, depending upon the pH of the solution, cadmium united with one or two moles of BAL to form two different complexes Cd-BAL and Cd (BAL). Cadmium also formed similar complexes with BAL glucoside, thiosorbitol, and thioxyolate. Although the Cd-(BAL)<sub>2</sub> complex had a low dissociation constant in vitro, a readily available supply of cadmium ions seemed to be available when this complex was preformed and then injected into rabbits. Depending upon the amount given, the animals died either acutely from typical cadmium poisoning or several days later from renal impairment. Preformed Cd (BAL glucoside)<sub>2</sub> proved to be relatively non-toxic, probably because the complex is too large to be absorbed readily by the renal cells.

Both BAL and BAL glucoside were found to increase the excretion of cadmium from cadmium-poisoned animals. The BAL-treated animals showed an increase in both urinary and fecal cadmium, whereas those treated with BAL glucoside showed an increase in urinary cadmium only.<sup>78</sup>

In an extensive inhalation study in dogs and mice, it has been shown that cadmium mists can cause acute death from massive pulmonary edema, or delayed death from diffuse pneumonitis often associated with lung abscesses, anorexia, bloody diarrhea and generalized wasting. BAL prevented death in a number of animals when it was given one to three hours after the cadmium exposure. However, when BAL was given prior to the exposure to cadmium, it actually hastened death, presumably by fixing the cadmium in the lungs, where it could do the most damage.<sup>79</sup>

### SILVER

In a limited study, Olcott and Riker<sup>80</sup> found BAL ineffective against experimental argyria. They gave small daily doses of silver nitrate to 2 white rats for four hundred and fifty-six days. One animal was then given nine injections of BAL over a period of eighteen days. Autopsy and histologic examination showed no essential differences in the amounts of silver deposited in the two animals. The authors concluded that BAL would probably be of no value in the treatment of argyria in man.

### MISCELLANEOUS METALS

#### Antimony

Barron and Kalnitsky<sup>86</sup> reported that attempts to reactivate the succinoxidase enzyme system inhibited by antimony were unsuccessful with BAL, whereas glutathione was effective in reversing this inhibition. On the other hand, Thompson and

Whittaker<sup>85</sup> found that BAL not only protected the brain pyruvate oxidase system from inhibition by antimony but also protected rats poisoned with this metal. Eagle and his co-workers<sup>81</sup> observed that BAL protected rabbits poisoned with various antimony compounds. An increase in antimony excretion in the urine persisting for two to four hours occurred after each injection of BAL. Similar results were obtained by Braun et al.<sup>73</sup>

#### Tellurium

Amdur<sup>82</sup> used BAL to treat 3 men who had inhaled tellurium-containing fumes and developed a characteristic garliclike odor of the breath. Although BAL failed to cause an increased urinary excretion of tellurium, the author believed that it was instrumental in decreasing the duration of halitosis from a possible period of weeks or months to a period of eleven to fourteen days in each case.

#### Copper, Bismuth, Chromium, Nickel, Zinc, Thallium, Selenium and Vanadium

McDonald<sup>83</sup> has reported that BAL glucoside in small doses caused an increased urinary copper excretion in normal sheep. The excretion reached a maximum of thirty times normal within an hour and then fell rapidly to a normal rate.

In enzyme-inhibition studies, Barron and Kalnitsky<sup>86</sup> found that BAL was effective against zinc, only partly effective against bismuth and totally ineffective against vanadium and selenium. Braun et al.,<sup>73</sup> in animal experiments, found BAL to be an effective antidote in poisoning from bismuth, chromium and nickel, but of no value against thallium and selenium. The administration of BAL actually hastened the death of animals poisoned with the latter metal.

### ALLOXAN

Lazarow<sup>84</sup> reported that large doses of monothiois such as cysteine, glutathione and thioglycolic acid completely protected rats against a diabetogenic dose of alloxan. The dithiol BAL in smaller amounts was found to be equally effective in protecting the animals from alloxan. However, neither the dithiol nor the monothiois protected the animals unless given before or immediately after the administration of alloxan. It has been postulated that alloxan causes an immediate, irreversible change, which can be prevented only by the early use of sulfhydryl groups, and, in contrast to heavy-metal poisonings, this change cannot be reversed by dithiois.

### PHENYLTHIOUREA

After the introduction of phenylthiourea and ANTU (alpha-naphthyl-thiourea) as powerful rodenticidal agents, a search has been made for suitable antidotes to be used in cases of accidental

poisonings Harvey and his co-workers,<sup>55</sup> on the basis of the findings of Du Bois<sup>56</sup> that ANTU inhibits sulfhydryl-containing enzymes, investigated the value of BAL and 1-thiosorbitol in phenylthiourea poisoning. ANTU and phenylthiourea are similar in action, and the latter was used in this experiment because of its greater solubility in water. The authors found that 1-thiosorbitol given to rats immediately after the administration of phenylthiourea protected these animals from the toxic and lethal effects of phenylthiourea. On the other hand, BAL increased rather than decreased the toxic effects of phenylthiourea. This paradox of a monothiol affording protection from a substance while a dithiol increases the toxic effects of that substance is similar to a situation seen in cadmium poisoning in which thiosorbitol is effective but BAL fails and even potentiates the action of cadmium.

### DOSAGE SCHEDULES

Sufficient experience in the use of BAL has been accumulated to permit tentative recommendations concerning proper dosage schedules for the treatment of arsenic and mercury poisonings. However, too little clinical information is available, as yet, to justify the formation of specific dosage regimens for the use of BAL in other metal poisonings.

The Council on Pharmacy and Chemistry of the American Medical Association<sup>57</sup> suggests that BAL be given by intramuscular injection according to the following schedules:

*For severe arsenic reactions*, each injection to contain 3 mg of BAL per kilogram of body weight

First day } 6 injections per day, at the rate  
Second day } of one injection every four hours

Third day 4 injections

Following ten }  
days or until } 2 injections per day  
recovery

*For mild arsenic reactions*, each injection to contain 2.5 mg per kilogram

First day } 4 injections per day  
Second day }

Third day 2 injections

Following ten }  
days or until } one injection per day  
recovery

*For mercury poisoning*, larger doses of BAL are suggested. An initial dose of 5 mg per kilogram of body weight should be given, to be followed in one to two hours by a dose of 2.5 mg per kilogram. After two to four hours a second dose of 2.5 mg should be administered, and in

severe cases a third dose of 2.5 mg should be given within the first twelve hours. On the second day, two doses of 2.5 mg per kilogram should be used, and on the third day one dose of 2.5 mg per kilogram is to be given.

Woodr and Kometani<sup>52</sup> successfully treated 42 infants and children with BAL for arsenic poisoning. Children suspected of arsenic ingestion but without symptoms of arsenic poisoning were given three to six doses of 2.5 mg per kilogram of body weight each at intervals of four to eight hours. Children with mild symptoms of arsenic poisoning were given six to twelve doses of 2.5 to 3.5 mg per kilogram each at intervals of four to eight hours. Those with severe symptoms were given six to twelve doses of 3.5 to 5.0 mg per kilogram each at intervals of four to eight hours.

### SUMMARY

BAL (2,3-dimercaptopropanol) was developed as an antidote against poisoning from the arsenic-containing war gas, lewisite. Since it is easily oxidized and unstable in aqueous solutions, BAL is commercially available only in a preparation containing peanut oil and benzyl benzoate, which is suitable for intramuscular administration alone. BAL is of value in the treatment of certain metal poisonings because it displaces the metal from its combination with the sulfhydryl groups of enzyme proteins with the formation of a metal-BAL complex, which is excreted. Although BAL in therapeutic doses may produce unpleasant side effects these are transient. BAL has been shown to be of clinical value in the treatment of arsenic, mercury and gold poisonings. Further clinical studies are necessary before the efficacy of BAL in other metal poisonings can be evaluated. Studies on animals suggest that BAL actually enhances the toxicity of certain metals. Therefore, BAL should not be used indiscriminately in the treatment of metal poisonings.

when BAL is given thirty minutes after the administration of cadmium is explained by the supposition that some of the cadmium becomes irreversibly fixed in the tissues, and thus a smaller amount eventually reaches the kidneys

The same authors found that, depending upon the pH of the solution, cadmium united with one or two moles of BAL to form two different complexes Cd-BAL and Cd (BAL)<sub>2</sub>. Cadmium also formed similar complexes with BAL glucoside, thiosorbitol, and thioxylate. Although the Cd-(BAL)<sub>2</sub> complex had a low dissociation constant in vitro, a readily available supply of cadmium ions seemed to be available when this complex was preformed and then injected into rabbits. Depending upon the amount given, the animals died either acutely from typical cadmium poisoning or several days later from renal impairment. Preformed Cd (BAL glucoside)<sub>2</sub> proved to be relatively non-toxic, probably because the complex is too large to be absorbed readily by the renal cells.

Both BAL and BAL glucoside were found to increase the excretion of cadmium from cadmium-poisoned animals. The BAL-treated animals showed an increase in both urinary and fecal cadmium, whereas those treated with BAL glucoside showed an increase in urinary cadmium only.<sup>78</sup>

In an extensive inhalation study in dogs and mice, it has been shown that cadmium mists can cause acute death from massive pulmonary edema, or delayed death from diffuse pneumonitis often associated with lung abscesses, anorexia, bloody diarrhea and generalized wasting. BAL prevented death in a number of animals when it was given one to three hours after the cadmium exposure. However, when BAL was given prior to the exposure to cadmium, it actually hastened death, presumably by fixing the cadmium in the lungs, where it could do the most damage.<sup>79</sup>

### SILVER

In a limited study, Olcott and Riker<sup>80</sup> found BAL ineffective against experimental argyria. They gave small daily doses of silver nitrate to 2 white rats for four hundred and fifty-six days. One animal was then given nine injections of BAL over a period of eighteen days. Autopsy and histologic examination showed no essential differences in the amounts of silver deposited in the two animals. The authors concluded that BAL would probably be of no value in the treatment of argyria in man.

### MISCELLANEOUS METALS

#### *Antimony*

Barron and Kalnitsky<sup>56</sup> reported that attempts to reactivate the succinoxidase enzyme system inhibited by antimony were unsuccessful with BAL, whereas glutathione was effective in reversing this inhibition. On the other hand, Thompson and

Whittaker<sup>55</sup> found that BAL not only protected the brain pyruvate oxidase system from inhibition by antimony but also protected rats poisoned with this metal. Eagle and his co-workers<sup>81</sup> observed that BAL protected rabbits poisoned with various antimony compounds. An increase in antimony excretion in the urine persisting for two to four hours occurred after each injection of BAL. Similar results were obtained by Braun et al.<sup>73</sup>

#### *Tellurium*

Amdur<sup>82</sup> used BAL to treat 3 men who had inhaled tellurium-containing fumes and developed a characteristic garliclike odor of the breath. Although BAL failed to cause an increased urinary excretion of tellurium, the author believed that it was instrumental in decreasing the duration of halitosis from a possible period of weeks or months to a period of eleven to fourteen days in each case.

#### *Copper, Bismuth, Chromium, Nickel, Zinc, Thallium, Selenium and Vanadium*

McDonald<sup>83</sup> has reported that BAL glucoside in small doses caused an increased urinary copper excretion in normal sheep. The excretion reached a maximum of thirty times normal within an hour and then fell rapidly to a normal rate.

In enzyme-inhibition studies, Barron and Kalnitsky<sup>56</sup> found that BAL was effective against zinc, only partly effective against bismuth and totally ineffective against vanadium and selenium. Braun et al.,<sup>73</sup> in animal experiments, found BAL to be an effective antidote in poisoning from bismuth, chromium and nickel, but of no value against thallium and selenium. The administration of BAL actually hastened the death of animals poisoned with the latter metal.

### ALLOXAN

Lazarow<sup>84</sup> reported that large doses of monothiols such as cysteine, glutathione and thioglycolic acid completely protected rats against a diabetogenic dose of alloxan. The dithiol BAL in smaller amounts was found to be equally effective in protecting the animals from alloxan. However, neither the dithiol nor the monothiols protected the animals unless given before or immediately after the administration of alloxan. It has been postulated that alloxan causes an immediate, irreversible change, which can be prevented only by the early use of sulfhydryl groups, and, in contrast to heavy-metal poisonings, this change cannot be reversed by dithiols.

### PHENYLTHIOUREA

After the introduction of phenylthiourea and ANTU (alpha-naphthyl-thiourea) as powerful rodenticidal agents, a search has been made for suitable antidotes to be used in cases of accidental

poisonings Harvey and his co-workers<sup>55</sup> on the basis of the findings of Du Bois<sup>56</sup> that ANTU inhibits sulfhydryl-containing enzymes, investigated the value of BAL and l-thiosorbitol in phenylthiourea poisoning. ANTU and phenylthiourea are similar in action, and the latter was used in this experiment because of its greater solubility in water. The authors found that l-thiosorbitol given to rats immediately after the administration of phenylthiourea protected these animals from the toxic and lethal effects of phenylthiourea. On the other hand, BAL increased rather than decreased the toxic effects of phenylthiourea. This paradox of a monothiol affording protection from a substance while a dithiol increases the toxic effects of that substance is similar to a situation seen in cadmium poisoning in which thiosorbitol is effective but BAL fails and even potentiates the action of cadmium.

### DOSAGE SCHEDULES

Sufficient experience in the use of BAL has been accumulated to permit tentative recommendations concerning proper dosage schedules for the treatment of arsenic and mercury poisonings. However, too little clinical information is available, as yet, to justify the formation of specific dosage regimens for the use of BAL in other metal poisonings.

The Council on Pharmacy and Chemistry of the American Medical Association<sup>57</sup> suggests that BAL be given by intramuscular injection according to the following schedules:

*For severe arsenic reactions*, each injection to contain 3 mg of BAL per kilogram of body weight

First day } 6 injections per day, at the rate  
Second day } of one injection every four hours

Third day 4 injections

Following ten }  
days or until } 2 injections per day  
recovery

*For mild arsenic reactions*, each injection to contain 2.5 mg per kilogram

First day } 4 injections per day  
Second day }

Third day 2 injections

Following ten }  
days or until } one injection per day  
recovery

*For mercury poisoning*, larger doses of BAL are suggested. An initial dose of 5 mg per kilogram of body weight should be given, to be followed in one to two hours by a dose of 2.5 mg per kilogram. After two to four hours a second dose of 2.5 mg should be administered, and in

severe cases a third dose of 2.5 mg should be given within the first twelve hours. On the second day, two doses of 2.5 mg per kilogram should be used and on the third day one dose of 2.5 mg per kilogram is to be given.

Woodv and Kometani<sup>52</sup> successfully treated 42 infants and children with BAL for arsenic poisoning. Children suspected of arsenic ingestion but without symptoms of arsenic poisoning were given three to six doses of 2.5 mg per kilogram of body weight each at intervals of four to eight hours. Children with mild symptoms of arsenic poisoning were given six to twelve doses of 2.5 to 3.5 mg per kilogram each at intervals of four to eight hours. Those with severe symptoms were given six to twelve doses of 3.5 to 5.0 mg per kilogram each at intervals of four to eight hours.

### SUMMARY

BAL (2,3-dimercaptopropanol) was developed as an antidote against poisoning from the arsenic-containing war gas, lewisite. Since it is easily oxidized and unstable in aqueous solutions, BAL is commercially available only in a preparation containing peanut oil and benzyl benzoate, which is suitable for intramuscular administration alone. BAL is of value in the treatment of certain metal poisonings because it displaces the metal from its combination with the sulfhydryl groups of enzyme proteins with the formation of a metal-BAL complex, which is excreted. Although BAL in therapeutic doses may produce unpleasant side effects, these are transient. BAL has been shown to be of clinical value in the treatment of arsenic, mercury and gold poisonings. Further clinical studies are necessary before the efficacy of BAL in other metal poisonings can be evaluated. Studies on animals suggest that BAL actually enhances the toxicity of certain metals. Therefore, BAL should not be used indiscriminately in the treatment of metal poisonings.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, *Editor*

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

### CASE 34531

#### PRESENTATION OF CASE

A sixty-one-year-old man was admitted to the hospital because of vomiting and diarrhea of one year's duration.

The diarrhea, which was described as occurring five or six times daily, was watery, brownish and without gross evidence of blood. The vomiting occurred once or twice a week, usually at night after retiring. It was accompanied by moderate epigastric fullness and dull substernal discomfort, which were not apparently related to food ingestion. In the six months before admission frequency of the attacks of vomiting increased to almost every night. At this time the patient noted the onset of burning and rolling sensations in the pit of the stomach. These symptoms were relieved somewhat by the emesis, which was liquid and mucoid in character. Anorexia was very marked. There was no postprandial distress, pain between meals, tarry stools or jaundice. He had lost 70 pounds since the onset of illness.

The past history revealed rheumatoid arthritis since the age of thirty years, when he had a severe attack with involvement of almost every joint. A bilateral knee-joint reconstruction was done after the acute stage. At this time he experienced the onset of mild exertional dyspnea and dependent edema. In spite of this he was alleged to have been in good general health but was unable to work because of the arthritis.

Physical examination revealed an extremely cachectic man in no acute distress. The chest was emphysematous, with limited expansion. There were moist, sibilant rales in the left axilla and at both bases. The heart was not enlarged. The liver edge was palpated four fingerbreadths below the costal margin. The spleen was not felt. A large reducible, supraumbilical, ventral hernia was present. Marked arthritic changes involving almost every joint, with limitation of movements, were observed. These appeared to be in a quiescent stage.

The temperature was 99°F, the pulse 80, and the respirations 20. The blood pressure was 120 systolic, 80 diastolic.

Examination of the blood showed a red-cell count of 5,300,000, with a hemoglobin of 12 gm, and a white-cell count of 21,300, with 70 per cent neutrophils. The urine had a specific gravity of 1.014 and contained no albumin. Subsequent specimens gave +++ to ++++ tests for albumin. There were a few white cells in the sediment. The nonprotein nitrogen was 50 mg, and the total protein 7.75 gm per 100 cc, with an albumin of 3 gm and a globulin of 4.75 gm. The chloride was 108 milliequiv per liter, and the alkaline phosphatase 6.6 units. The prothrombin time was 17 seconds (normal, 16 seconds); the cephalin flocculation test was ++ at twenty-four hours and +++ at forty-eight hours, and the bromsulfalein test showed 10 per cent retention of the dye. A Congo-red test revealed a 52 per cent retention of dye in the serum.

X-ray studies of the gastrointestinal tract gave findings suggestive of pyloric obstruction, with marked pylorospasm. A barium enema was negative. A chest film showed extensive fibrotic emphysematous and bronchiectatic changes in both lungs. An electrocardiographic record was within normal limits. The gastric fluid on analysis revealed high acidity and was guaiac negative. Cytologic study of smears was reported negative. The stools were guaiac negative. After admission repeated gastric aspirations of 150 to 300 cc resulted in some decrease of the vomiting, but the patient continued complaining of gastric fullness.

On the eighth hospital day a partial gastrectomy and repair of the ventral hernia were performed. Following operation he noted no relief of the gastric fullness and complained of increasing pain and stiffness of joints. The nonprotein nitrogen began to rise, from 50 mg to 72 to 170 mg, finally reaching 225 mg per 100 cc, with a fall of the chloride to 78 milliequiv per liter and of the total protein to 5.4 gm per 100 cc. The watery diarrhea recurred, and marked dyspnea and cyanosis developed. Moist rales were heard almost to the top of both lungs. On the twenty-second hospital day he became unresponsive and died.

#### DIFFERENTIAL DIAGNOSIS

DR BERNARD M JACOBSON: Can you tell us the figures on the acidity of the gastric fluid?

DR TRACY B MALLORY: A fasting specimen was reported as 50 units of free and 80 units of combined acid.

DR JACOBSON: A considerable degree of acidity.

As I read over this patient's history and before I got to the report of the x-ray examination, a number of thoughts occurred to me about the fundamental diagnosis. Apparently for a considerable period of time there was a watery, brownish diarrhea without gross evidence of blood but with associated cramps in the lower abdomen. The diarrhea seemed more prominent than the vomiting, which occurred only once or twice a week, usually after retiring. The

possibilities that ran through my mind as causes of long-continued diarrhea without pus or blood or tenesmus include a few common conditions and a few unusual conditions that might be mentioned. Against such a condition as ulcerative colitis or regional ileitis was the lack of blood, pus or tenesmus. The presence of a carcinomatous lesion anywhere in the gastrointestinal tract from the stomach downward should certainly be considered. The question of a fistula between various segments of the gastrointestinal tract must be considered, and that could account for this type of diarrhea. The possibilities outside the gastrointestinal tract — general and systemic disease that can cause this type of diarrhea — come to mind. Chronic uremia is one of the commonest. Chronic nitrogen retention can be associated with this type of diarrhea and last many months. One thinks of such diseases as Addison's disease as causing diarrhea and vomiting and also of pernicious anemia and sprue, but the subsequent physical and laboratory findings give no evidence for either Addison's disease, pernicious anemia or sprue, nor is there any evidence later on that suggests hyperthyroidism as the cause of that type of diarrhea. As one goes along a little bit in the history, one finds that when the vomiting became more pronounced, beginning to occur almost daily, the material vomited was liquid and mucoid. I presume we would know from the patient whether the liquid was heavily stained with bile because that is usually mentioned at some time in a patient's history. In the absence of small-bowel content of the vomitus I think we must assume that there was obstruction at the pylorus. This was not low intestinal obstruction. The amount of vomiting, it seems to me, is out of proportion to what we may expect as secondary to some of the systemic diseases I have mentioned.

On physical examination the liver edge was four fingerbreadths below the costal margin. In view of the obvious emphysema I assume the upper border was quite low and the liver was not large but merely ptotic. I am rather surprised we were not told about the examiner's feeling a mass in the abdomen, especially in the presence of the hernia. Perhaps I should not expect to feel a mass, but I think I do.

As far as the laboratory work goes, there are a few items of interest. A mild hypochromic anemia was present. We are told that one urine on admission had a specific gravity of 1.014, probably the patient did not have a specific-gravity concentration test, but it would be of some interest to know if he could concentrate. Most of the urine apparently contained a huge amount of albumin and a few pus cells. I would be interested to know if the patient had an intravenous phenolsulfonephthalein test, since we see later that kidney failure played an important part in the patient's terminal career.

DR MALLORY There was a phenolsulfonephthalein excretion of 0 in fifteen minutes, 5 per cent in sixty and 5 per cent in twelve

DR JACOBSON What volume?

DR MALLORY No volume was recorded.

DR JACOBSON Assuming that the urinary volume was fairly good, this obviously indicates impairment in renal function — no excretion in fifteen minutes.

DR MALLORY No concentration test is recorded but subsequent specific gravities are 1.005, 1.003, 1.010 and 1.006.

DR JACOBSON Reversal of the albumin-globulin ratio is of some interest, suggesting systemic disease with increasing serum globulin. There is no good evidence of any one disease. Some degenerative disease of the liver might have caused this high serum globulin. Rheumatoid arthritis can sometimes cause high serum globulin. I doubt if that would be suggestive of multiple myeloma or sarcoid or some of the other conditions. I suspect that the globulin may be elevated due to rheumatoid arthritis. The amount of liver-function defect, as measured by the cephalin flocculation and bromsulfalein test, is of no great significance in a person as malnourished as this. Later we note the low serum chloride, which was initially rather high, perhaps because of dehydration. The phosphatase of 6.6 units is against biliary obstruction. The normal prothrombin time is also against marked derangement of liver function.

DR STANLEY M. WYMAN The films of the chest show a diffuse linear process throughout both lung fields extending from the hilum. There are suggestions of dilated bronchi in the periphery of the right-upper-lung field. The hilar shadows are prominent, but I can see no definite lymph nodes or other masses. The heart shadow is not remarkable for a man of this age. The chest is increased in the anteroposterior diameter, and I think the whole picture is quite consistent with fibrosis and emphysema, although of course lymphatic metastases cannot be entirely excluded. The films of one barium-enema examination show an intrinsically normal-appearing colon, with a loop of barium-filled bowel, I think probably ileum, extending out into the hernial sac and other gas-filled loops of bowel, which are probably ileum in the sac. The hepatic flexure is displaced downward, and the upper margin of the liver extends reasonably high, which makes me wonder about increase in the size of the liver from this examination.

The next films are of the gastrointestinal examination done on at least two occasions. I am sure the examiner had a great deal of difficulty with this patient because of the arthritis. I think the important thing on these films is that there is a large, soft-tissue shadow in the right upper quadrant that I believe displaced the duodenum and stomach to the left, and, as one can see in this projection, this lies somewhat anteriorly. Apparently, the examiner had a great deal of difficulty in obtaining good visualization of the pylorus and the distal duodenum, and we have no film with good filling of the distal duodenum. The few traces that we have of barium in the duodenum show a suggestion of some irregularity

in the mucosal pattern. There is a suggestion of some radiolucency overlying the liver. This, again, is not a definite finding. The film that might have shown it best is of unsatisfactory quality. There is one, and only one, spot film that shows an unusual accumulation of barium at this point, which makes one wonder about barium in the common duct. I would say that the liver was enlarged and displaced the stomach. It may be that the second portion of the duodenum is narrowed. I cannot comment intelligently on the pylorus. The changes may be due to extrinsic pressure.

DR JACOBSON: Dr Wyman has pointed out that the upper portion of the liver was not low as I suspected and that the stomach was apparently pushed to the left. In that case we must believe the liver was large and was the seat of disease.

The Congo-red test, which showed 52 per cent retention, apparently a doubtful borderline finding, gave no definite evidence of systemic amyloid disease. There are certain forms of amyloid disease — the atypical type that might infiltrate the walls of the small bowel — that will not take up Congo-red dye. We cannot see any visualization of the small bowel — no leakage of barium directly into the colon.

DR WYMAN: I should not say so.

DR JACOBSON: If we could have a picture of the upper small bowel, it would be helpful.

DR WYMAN: This is the closest we came to it. I would consider these jejunal folds to be within normal limits.

DR JACOBSON: Was an intravenous pyelogram done?

DR WYMAN: No.

DR JACOBSON: I rather suspect that the correct diagnosis was not well understood preoperatively and that some of the reasoning that I have gone through was also discussed by the clinicians on the service before operation. This patient obviously had pyloric obstruction. We must assume vomiting secondary to pyloric obstruction and not systemic disease.

What of the diarrhea? We have no evidence of intrinsic small-bowel or large-bowel disease. Can we tie up the vomiting and the diarrhea into one diagnosis? It is possible if we assume that the patient had carcinoma of the pylorus. Many patients with carcinoma of the stomach have diarrhea, the exact mechanism of which we do not know. The evidence for carcinoma of the stomach in this patient is the progressive downhill course. The history of the type of discomfort he had in the stomach is perfectly consistent with it. For the diagnosis of pyloric obstruction due to ulcer there may be more evidence from the laboratory point of view — high gastric acidity and the negative cytologic smear. The lack, however, of a good, clear history of postprandial pain typical of ulcer stands out, and the combination of pyloric obstruction and diarrhea inclines me a little more to the diagnosis of carcinoma rather than ulcer. Some

few cases of carcinoma do have high gastric acidity. I cannot visualize any other specific cause for diarrhea.

What happened after operation is certainly an interesting phenomenon. The kidney failure, which may have been very minimal before operation, set in quite promptly. The patient obviously died in uremia. Terminally he had left-sided heart failure and pulmonary edema.

I believe that in recent years major surgery in patients with cardiac disease has become less and less of a risk and that the experience of many surgeons and physicians is that renal failure is probably a most important postoperative condition.

What was the renal failure due to? We have no good evidence that this patient had chronic glomerulonephritis or chronic vascular nephritis, although it may well be that the initial blood pressure of 120 systolic, 80 diastolic, reflected a man with some degree of heart failure, with lowered blood pressure. Against increased hypertension is the fact that the heart shadow was normal.

Could this have been pyelonephritis? It certainly could. At these sessions Dr Mallory has pointed out to many of us how often we miss the diagnosis of chronic pyelonephritis. The diagnosis is not too easy to make. The findings in the urinary sediment when the patient comes to the hospital may be minimal, and the blood pressure elevated or normal, all forms of kidney-function tests, of course, are markedly abnormal.

Could this have been an acute renal failure due to lower-nephron defect? We have no history of the patient's having received sulfonamides or incompatible transfusion. I shall assume that they were not given, and the possibility can be discarded.

I should like to conclude with a diagnosis of carcinoma of the pylorus, diarrhea secondary to the carcinoma, chronic pyelonephritis, terminal uremia, rheumatoid arthritis, bronchiectasis and terminal heart failure.

DR F DENNETTE ADAMS: I am worried about Dr Jacobson's statement that he attributed the lower border of the liver and low diaphragm to emphysema. I doubt if it could happen. I do not believe I have seen it due to that, but I may be wrong. It seems to me that a low diaphragm due to emphysema would not have enough pressure to push the liver down.

I would like to ask if perhaps amyloid disease would explain the terminal picture, especially in a man with arthritis for so many years.

DR JACOBSON: I think I have seen a low liver — that is, a ptotic liver — pushed down by the diaphragm, even without pulmonary emphysema. In view of the demonstration of the soft-tissue mass by Dr Wyman, I am more suspicious that the liver was the seat of carcinomatous metastases.

Against amyloid disease, I do not believe the rheumatoid arthritis was active enough to produce that

much amyloid disease. The Congo-red test was not conclusive, nor was there enough bronchiectasis in the history to suggest amyloid disease secondary to that.

DR JOHN B STANBURY I was much impressed by one interesting physical finding. You could pass your hand through the ventral hernia and outline a firm, smooth liver as I have never been able to do before — just as well as Dr Mallory could examine it at post-mortem examination.

The thing that puzzled us was why after operation the patient suddenly went into renal failure. He had borderline failure before operation. He had pyloric obstruction preceding operation. We took the risk. It did not work. He went quickly into renal failure, developed uremia, pulmonary edema and low chloride, went into pulmonary edema and heart failure and died. We gave him no sulfonamide.

DR JACOBSON No mass was felt in the abdomen through the hernia?

DR STANBURY No, just the liver.

#### CLINICAL DIAGNOSIS

Amyloid nephropathy, with uremia

#### DR JACOBSON'S DIAGNOSES

Carcinoma of pylorus  
Chronic pyelonephritis  
Terminal uremia  
Rheumatoid arthritis  
Bronchiectasis  
Terminal heart failure

#### ANATOMICAL DIAGNOSES

*Rheumatoid arthritis, chronic*  
*Amyloidosis of liver, spleen, kidneys and adrenal glands*  
Bronchiectasis  
Bronchopneumonia  
Hypertrophy of heart  
*Pericarditis, acute fibrinous, probably uremic*  
Operative wound resection of pylorus for obstruction

#### PATHOLOGICAL DISCUSSION

DR MALLORY Autopsy showed that several of the organs were larger than the x-ray examinations indicated. The heart weighed over 500 gm, and the liver 3500 gm — double the normal size. The spleen weighed 500 gm, and both kidneys 450 gm. We found that the liver, spleen and kidneys showed very extensive amyloid disease and there was also some involvement of the adrenal glands. There was extensive bronchiectasis, a terminal bronchopneumonia and an acute pericarditis. The stomach, which had been resected, was a great disappointment to the pathologists. We could find nothing wrong with it.

At the time of operation a biopsy on which a frozen section was done showed only normal, smooth muscle, and the resected specimen only questionable hypertrophy of the muscle of the pyloric ring and perfectly normal mucosa — neither tumor nor ulcer. Localized amyloid tumors of the gastrointestinal tract do occur, and in the face of extensive amyloid disease we thought we might find amyloid in the pyloric ring, but there was none whatever.

DR EDWARD B D NEUHAUSER Why was a gastrectomy done?

DR STANBURY There seemed to be no question that the patient had functional pyloric obstruction. Perhaps a surgeon can answer that.

DR W R RICHARDSON I am sorry that Dr John McKittrick is not here. I assisted at the operation and shall try to explain our findings and the choice of procedure.

A gastrotomy was done, and the pylorus and pyloric antrum visualized. There was a definite organic obstruction at the pylorus, an annular thickening that was submucosal with no ulceration. It narrowed the lumen to a diameter of less than 1 cm and did not permit the passage of more than the distal portion of a hemostat. This band was broken down during the digital examination, with several linear mucosal tears resulting. Much of the band was removed submucosally and sent for frozen-section diagnosis, which revealed no evidence of a malignant lesion and was eventually noted as "hypertrophy of the pylorus."

Subtotal gastrectomy was performed because it was considered inadvisable to leave traumatized areas. That this was probably an unfortunate choice is now clear, and we would have felt much better had a gastroenterostomy or even a pyloroplasty been carried out, accepting whatever hazard there might have been in leaving the traumatized pylorus and pyloric antrum.

DR MALLORY One cause of pyloric obstruction seen from time to time in adults is ectopic pancreatic tissue in the pyloric sphincter. We looked carefully for that but were unable to find it. I think we must assume that the pyloric obstruction was functional. I have no doubt it was real.

DR JACOBSON Would Dr Ropes comment on the significance of the Congo-red test?

DR MARIAN ROPES I think we have now seen enough cases corroborated at autopsy to say that this figure may mean amyloid disease. We still do not know what the percentages mean, but half our patients with rheumatoid arthritis show levels between 50 and 65 per cent and several have shown amyloid disease at autopsy. In addition, 15 per cent have positive levels — less than 50 per cent left in the serum. It is interesting also that the Congo-red retention does not seem to correspond with the severity of the arthritis or with the duration. We

have seen it in varying degrees of severity of arthritis.

DR MALLORY The amyloid deposits stained beautifully with Congo red at autopsy. It was the type that should have absorbed dye, I should think.

## CASE 34532

### PRESENTATION OF CASE

A forty-nine-year-old photographer entered the hospital complaining of dyspnea relieved by belching.

Five months before admission he experienced an episode of nausea, weakness and pain in the left arm which was relieved by induced vomiting. He remained in bed for three days, and at this time a chest x-ray film showed an enlarged heart. He continued his usual activities but three months later awoke one night with sudden dyspnea, relieved by sitting on the edge of the bed for a few minutes. Since that time he had noticed gradually increasing dyspnea on exertion and frequent episodes of epigastric distress following meals, often associated with dyspnea.

Ten days prior to admission he noticed swelling of the ankles, which increased subsequently. During the past few months he had lost about 15 pounds.

Physical examination revealed a well developed, quiet man in no distress. The cardiac border was percussed 11 cm to the left of the midline. There was a questionable diastolic gallop. The liver edge was palpated four fingerbreadths below the costal margin and was slightly tender. There was ++ edema of the ankles, extending up to the sacrum.

The temperature was 99.4°F, the pulse 90 and the respirations 24. The blood pressure was 115 systolic, 90 diastolic.

Examination of the blood revealed a hemoglobin of 14 gm, and a white-cell count of 12,000, with 77 per cent neutrophils, 19 per cent lymphocytes and 4 per cent monocytes. The urine had a specific gravity of 1.026 and gave a +++ test for albumin. Microscopical examination of the sediment showed rare red cells and 5 to 8 white cells per high-power field.

On the day following admission he experienced sudden pain in the right upper chest with a little sputum. Later a friction rub was heard on the right side, and a few rales at the right back. An x-ray film disclosed an area of somewhat mottled density lying in the anterior segment of the right upper lobe with its base against the pleura. There was a moderate quantity of fluid in the right pleural space. The lung fields otherwise appeared essentially clear except for some atelectasis in the right-lower-lung field medially. The heart shadow was enlarged to the right and left with a cardiothoracic ratio of 18/31.5, it was without characteristic configuration, and the pulsations were diminished in amplitude. Plain films of the abdomen showed the tip of the liver to lie unusually low, suggesting some enlargement of the

liver. There was a hazy density obscuring some of the visceral shadows and raising the question of fluid in the abdomen. An electrocardiogram showed a normal rhythm, with a rate of 100, and a PR interval of 0.14, the T waves were inverted in Lead I and low in Leads 2 and 3, and there was a well marked left-axis deviation and an inverted T wave in Lead AVL with a small Q wave. The chest leads showed an upright T wave in Leads V-2 and V-4 and a flat T wave in V-5.

On the day following the episode of chest pain a bilateral superficial femoral-vein ligation was performed and dicumarol and digitoxin were started. Tenderness of the right calf was noted on the next day. The patient continued to experience some dyspnea and occasionally raised some blood-streaked sputum. He began to run a temperature of about 100°F, and the rales at the right base persisted. The prothrombin activity became as low as 24 per cent, and digitoxin was stopped because he complained of nausea. An x-ray film on the seventh day again demonstrated the area of increased density within the anterior portion of the right upper lobe. This had increased in size since the previous examination. The right leaf of the diaphragm was considerably elevated. Very little, if any, fluid was made out. The left lung was clear. The heart was again observed to be markedly enlarged.

He continued to be nauseated and occasionally raised more bloody sputum. He developed a prominent gallop rhythm with occasional extrasystoles and dropped beats. He continued to fail slowly and developed pleural pain over the left chest posteriorly, with a loud friction rub. On the tenth hospital day he had a sudden episode of dyspnea and became increasingly cyanotic, with increase in pulse rate and lowering of blood pressure. Following this he was described as in a "chronic shock state" and died on the following day.

### DIFFERENTIAL DIAGNOSIS

DR GORDON S. MYERS May we see the x-ray films?

DR STANLEY M. WYMAN Unfortunately, we were unable to find any but these two portable films of the chest. They show the area of rather homogeneous density in the right-lung field, which appears to lie against the pleura of the anterior chest wall. There is some fluid in the fissure between the middle and lower lobes and the upper and lower lobes. The right lower lobe is decreased in size, and there is some density posteriorly, suggesting possibly another infarct. However, this film is of insufficient quality to warrant a definite conclusion. The heart shadow cannot be delineated, but it is a large heart, I believe, and is prominent in the region of the left ventricle. The left lung on these films appears clear.

DR MYERS Do you think the density here in the lower portion of the lobe as seen posteriorly can be consistent with pulmonary infarction?

DR WYMAN Yes, with some pleural fluid

DR BENJAMIN CASTLEMAN This last set of films was taken on the tenth day, six days before the patient died

DR MYERS I would like to begin by saying what I think the diagnosis may be and then try to explain my reasoning I believe this man most likely had coronary-artery disease and the onset of the acute illness began with myocardial infarction, although we have no proof of that I believe also that he had congestive failure and recurrent pulmonary emboli, both prior to and probably following treatment by superficial vein ligation and dicumarol

The chief complaint was that of dyspnea, relieved by belching That is an unusual chief complaint, but I suppose it is a valid one If he had congestive failure with limitation of vital capacity and gaseous distention of the abdomen, the elevation of the diaphragm may have been responsible for some additional dyspnea, since we believe that dyspnea is proportional to ventilation divided by vital capacity

Five months before admission this man had a curious episode of nausea, weakness and pain in the left arm, relieved by induced vomiting That in itself is a nonspecific history One would think, first of all, that he had something going on in the gastrointestinal tract In view of the fact that later on we find that he had lost weight despite the fact that he was becoming edematous, one might consider the possibility of carcinoma or some other serious lesion in the gastrointestinal tract This history does not suggest pulmonary infarction or embolus at that time The fact that he had pain in the left arm, even without chest pain, and that he had symptoms of indigestion certainly is consistent with the occurrence of myocardial infarction We know that myocardial infarcts sometime occur without any symptoms He remained in bed three days at this time He had chest x-ray films, which showed an enlarged heart If he had a myocardial infarct at this time, it might explain the fact that the heart appeared to be large on x-ray study and that he went on to symptoms suggesting left-sided heart failure Thus, we can justifiably suspect myocardial infarct, but we cannot make a definite diagnosis of it from the facts at hand

I think that the diagnosis of coronary-artery disease in a man forty-nine years old who showed congestive failure but no heart murmurs is the best bet It is very unlikely that he had one of the rarer kinds of heart disease such as those following sulfonamide therapy and virus infection We know that he had an episode of orthopnea He woke up short of breath and was relieved by sitting on the edge of the bed He had clear-cut dyspnea on exertion and also epigastric distress following meals, associated with dyspnea If he had coronary-artery disease the symptoms of indigestion were not unusual since we know various functional gastrointestinal diseases are commonly associated with coronary disease —

for example, cardiospasm, which gives symptoms of indigestion apart from the heart trouble He may have had dyspnea after meals, partly because of abdominal distention and also because the work of the heart is increased after a full meal

Ten days prior to admission he noted swelling of the ankles, which had increased Despite this, he had a 15-pound weight loss, and one wonders if he had some kind of cachectic disease I do not believe we can skip over that weight loss too lightly However, he may have been afraid to eat, simply because eating aggravated his symptoms Later on there is no clear-cut evidence of wasting disease such as thyrotoxicosis, cancer, diabetes or the like

The physical examination, as stated, is consistent with congestive heart failure there was a large heart, rapid pulse, a questionable diastolic gallop and so forth The protocol states that the blood pressure was 115 systolic, 90 diastolic It would be helpful to know if he had had any previous hypertension, whether or not there was venous distention, and also about the loudness of the pulmonic second sound, to get some idea whether there was pulmonary hypertension associated with left-sided heart failure

DR CASTLEMAN The record states that there was distention and pulsation of the neck veins for 5 cm above the clavicle

DR MYERS That is additional evidence in favor of congestive failure It certainly fits in with the rest of the picture

Examination of the blood showed no definite anemia, a little increase in white-cell count and no real increase in neutrophils or lymphocytes The urinary findings are consistent with the presence of congestive failure

On the day following admission the patient experienced sudden pain in the right upper chest, with cough productive of a little sputum, and later a friction rub and a few rales were noted This episode and the x-ray findings seem to be consistent with the presence of pulmonary infarction, although the small amount of fluid in the right pleural space could have been due either to congestive failure or to a pulmonary infarct that happened to be on the right side The x-ray report states that there was atelectasis in the right-lower-lung field, but I believe that is a not uncommon statement in cases of small pulmonary infarcts There may or may not have been additional atelectasis The heart was large, without any special configuration, perhaps prominent in the region of the left ventricle The cardiac pulsations were diminished I do not believe that fact to be too helpful Diminished pulsations may be due to the presence of pericardial fluid or simply to an enlarged, failing heart. There is certainly no evidence of constrictive pericarditis in the x-ray films or in the rest of the data that we have The plain films of the abdomen, which we do not have here, were consistent with the presence of fluid and an enlarged liver, which were probably due to congestive heart failure

We then come to the electrocardiograms. I am glad to have been able to see the tracings myself just now because they look a little more markedly deformed than one gathers from the description in the protocol. I am struck with the fact that there is a tendency to low voltage in the QRS complexes in the limb leads, and small R waves all across the chest with an M-shaped QRS wave in V-5. The rest of the tracing is as stated in the protocol. The electrocardiogram is certainly not diagnostic. If one takes electrocardiograms of a large number of patients with pulmonary emboli, only about 10 per cent show characteristic findings of acute cor pulmonale. Thus, we need not be surprised when the electrocardiogram does not give us the diagnosis even if the patient had, as I assume he did, pulmonary infarcts.

How about the question of myocardial infarction? Certainly this electrocardiogram per se is not diagnostic of either old or recent myocardial infarction, however, it is consistent with coronary-artery disease as well as with other diseases which I do not believe we need go into because there is no other evidence in favor of them. How can the electrocardiogram be so nonspecific in acute myocardial infarction? In the first place, electrocardiograms may occasionally actually revert to normal a few months after the occurrence of a myocardial infarct. The initial episode here was five months before admission. In the second place, the localization of the myocardial infarct may be such that the standard procedure for placing the electrodes in a routine electrocardiogram fails to show the infarction even though present. The electrocardiogram may thus be normal unless special efforts are made to explore the chest thoroughly or unless an esophageal lead is taken. Third, and most important, is that serial electrocardiograms very frequently help to make the diagnosis of myocardial infarction by showing specific changes in pattern where a single tracing is of no help. Apparently, only one electrocardiogram was taken in this case. We can summarize the electrocardiographic findings by saying that although they are not diagnostic they certainly do not rule out an old anterior infarction. They are, in any case, consistent with the presence of coronary-artery disease. They do not show the typical changes of acute cor pulmonale, but we cannot be surprised at this, even in the presence of multiple pulmonary infarcts.

Following the initial episode in the hospital a superficial femoral-vein ligation was done and dicumarol given. We know that superficial femoral-vein ligations are occasionally followed by repeated pulmonary emboli, which also occur after treatment with dicumarol. It is true that superficial femoral-vein ligation is rarely followed by fatal pulmonary emboli, the same reservation holds for adequate treatment with dicumarol. The statement is made that the prothrombin level went as low as 24 per cent. That is not the important point. The point is

whether over the period of treatment it had regularly been kept at a low level, somewhere between 10 and 30 per cent. If the prothrombin percentage gets down to 24 and a few days later it is up to 100, obviously we have inadequate protection for the patient. I think that the remainder of the story here is consistent with pulmonary infarcts despite the therapy that was carried out. The patient developed some cardiac arrhythmia. That may have been stimulated by the pulmonary emboli added to the presence of coronary-artery disease. The last episode before death, I believe, was more likely to have been a pulmonary embolism than myocardial infarction, although the latter is possible.

In summary, then, I believe that this patient had coronary-artery disease, with congestive failure. I believe there is a good possibility, although no proof, that he had myocardial infarction. I still think that the later episodes were pulmonary infarcts despite the dicumarol therapy and venous ligation.

DR WYMAN: It is an unusual story for a pulmonary infarct to increase in size during the course of seven days. We are given the information that it lies against the pleural surface, but that is not entirely clear-cut from this film. I think an additional possibility that one might worry about is tumor of the lungs. I cannot exclude it from this examination.

DR MYERS: I am grateful for your suggestion. Certainly, if there was some enlarging process in the lung atypical of pulmonary infarction, a tumor might help to explain the troublesome fact of marked weight loss in a case in which otherwise there is no definite explanation for it. I suppose the tumor if present, could have been primary in the lung or possibly metastatic from somewhere under the diaphragm. In the latter case, it might explain the gastrointestinal symptoms that the patient had.

DR JOHN B. QUINBY: What would be the source of the pulmonary emboli?

DR MYERS: I suppose from the figures available one could bet on a 75 per cent chance, from the legs and a 25 per cent chance from the heart chambers—in which case the emboli would arise from a mural thrombus.

DR QUINBY: Even with ligation?

DR MYERS: Yes. Only the superficial femoral-vein ligation was performed, the profunda was not included, and also there is the possibility of clots in the iliac vessels and higher up in the pelvis.

A PHYSICIAN: In how many cases of myocardial infarction have you seen the electrocardiogram return to normal?

DR MYERS: I do not know exactly how many do.

A PHYSICIAN: It certainly does occur occasionally, but how many have you seen?

DR MYERS: I cannot answer that. Dr White has some excellent illustrations in his book showing the return of electrocardiograms to normal following myocardial infarctions.

## CLINICAL DIAGNOSES

Arteriosclerotic heart disease  
 Coronary thrombosis, with myocardial infarction  
 Phlebothrombosis of leg, with pulmonary embolism and infarction

## DR MYERS'S DIAGNOSES

Coronary-artery disease, congestive heart failure, probable myocardial infarction  
 Multiple pulmonary infarcts

## ANATOMICAL DIAGNOSES

*Coronary thrombosis, with myocardial infarction*  
 Mural thrombi, left ventricle and both auricles  
*Pulmonary infarcts, multiple, massive*  
 Coronary sclerosis, severe  
 Cardiac hypertrophy  
 Hydrothorax, bilateral  
 Central congestion of liver  
 Renal infarct

## PATHOLOGICAL DISCUSSION

DR CASTLEMAN Autopsy showed an enlarged heart, which weighed 500 gm. The coronary arteries were very severely sclerotic. The left had a pinpoint lumen throughout, and the right was also narrowed but, in addition, contained a recently organized thrombus. The anterior portion of the left ventricle was completely infarcted. The infarction involved the interventricular septum and extended through to involve the right portion of the septum, which is a relatively rare occurrence. There was a large mural thrombus over the infarct on the left side, but none on the right. A piece of this thrombus had apparently broken off and had produced an infarct to one of the kidneys, which may perhaps account for the red cells that were found in the urine. There were mural thrombi also in both auricles so that the emboli in the lungs could be accounted for by the right auricular thrombus. The lungs were the site of numerous infarcts and very large ones, much larger than we usually see. The infarct in the right upper lobe measured 7 cm. in diameter. The increase in size of the x-ray shadow between the two sets of films was due to an infarct in the right middle

lobe that occurred later, and its shadow was superimposed upon that of the upper-lobe lesion. Some years ago Dr. Hampton<sup>2</sup> showed that increase in size and changes in shape of infarcts may be due to other infarcts occurring close by, and that was true in the case under discussion. In addition, the entire upper portion or dorsal division of the right lower lobe and almost the entire left lower lobe were infarcted. These probably occurred after ligation, since they appeared to be redder and more recent than the others. I have the impression, and it is only an impression, that in patients with heart failure that have auricular mural thrombi as a source of emboli, the infarcts are larger than those observed when the emboli arise from the leg veins. This certainly could be borne out in this case.

The liver was enlarged and showed a severe degree of central congestion. It is surprising that he did not develop jaundice with that degree of pulmonary infarction in addition to fairly severe liver disease.

There was about 200 to 300 cc. of straw-colored fluid in the right pleural cavity, and a similar amount on the left. I think it is surprising that one cannot see anything in the left lower lobe that suggests infarct. It measured 16 by 20 cm. at autopsy. Of course, it might well have occurred during the six days between death and the time this film was taken.

DR MYERS How old was the myocardial infarct?

DR CASTLEMAN There were several areas of recent frank necrosis and also areas of granulation tissue. I believe that some foci of infarction could have been two months old.

DR MYERS Were the leg veins examined?

DR CASTLEMAN Yes. At the time of operation no thrombi were found in the superficial femoral veins, and at autopsy the sites of the ligation were perfectly negative. Both profundas were examined and found free from thrombus. We did find a thrombus in the popliteal vein on the right, which I think occurred following ligation.

## A NEW YEAR

HUMILITY, best defined by Webster as "freedom from pride and arrogance," may be of various types and may constitute the mask that hides a variety of underlying patterns. Among these types are the self-debasing humility of the uncompensated inferiority complex, the sinister pseudohumility that characterizes the Uriah Heeps, the arrogant humility of conscious rectitude as expressed in Burton's *Anatomy of Melancholy* — "They are proud in humility, proud in that they are not proud."

There is also the honest humility of true magnanimity, fearless because it makes no pretence recognizing superior assets and capacities in others acknowledging powers higher than those that

humankind possesses, and admitting the likelihood that even the most capable person may sometimes be in error. It is a humility of the intellect free from pride and arrogance.

One of the errors to which any person of ambition may be liable — and the higher his road is built the deeper are the ditches that flank it — is the development of a belief in his own infallibility. Too often a genuine call to service turns with the passage of time and under the influence of personal prestige into a sense of superiority over those served. Too frequently a long period of unchallenged leadership may betray the leader into a belief in the permanence of his own position, even in his inability to make the wrong judgment. Obsessed with this feeling of unassailable righteousness, he unconsciously assumes the mantle of perfection and with it something in the way of self-bestowed divinity. In his estimation of himself he has caught up with God.

Especially vulnerable to this particular loss of perspective are those who have been drawn into fields of activity in which personal influence is a strong factor. Among these are politicians with their constituents, writers with their readers, teachers with their pupils, pastors with their parishioners, physicians with their patients. A penalty attached to their sometime loss of humility as expressed by an eminent preacher, is that they doubt God when it is themselves that they should doubt.

To them might be recalled the words of Cromwell to Parliament, the members of which he beseeched at one time to bear in mind that they "might be mistaken."

So for everyone a resolution with which to start a new year might be to bear in mind that he may be mistaken that true humility is a virtue that can be cultivated, and that conscious and outspoken humility is its own contradiction.

## MILESTONES

RELEASES from public-relations counsel at times seem like those from the butcher, replete with the lard of "significance" but shy of the lean of meaning. The copywriter's incomplete comparative is familiar: the better refrigerator, the better homes

and gardens, the better postwar automobiles Better than what? Attention is now invited by a Detroit committee of the automobile industry to a "significant" milestone, the production of a hundred million motor vehicles A significant milestone, it may be asked, on what road?

Since the first car, fifty-five years ago, production has been at an annual rate of nearly 2,000,000 vehicles until today more than 40,000,000 cars, trucks and busses crowd the nation's highways, one for every four persons in the United States Every minute of each working day sees 30 new cars and 10 new trucks and busses The second hundred millionth milestone should be reached in only twenty-five more years This informative committee avers that research and mass production have cut costs and increased sales, and in turn have increased employment, raised the nation's standard of living and expanded retail trade areas, indeed, whole new industries dependent upon this new flexible transportation tool have been developed Since the horseless-carriage tinkers have come out of their alleys and quit selling bicycles, the labor, the ingenuity and the lives of millions of Americans have been absorbed in the making, selling and servicing of automobiles Many thousands of other lives, it may be stated without exaggeration, have needlessly been sacrificed as a result of their labors

Comment has been made on accidents as a leading cause of death<sup>1 2</sup> The all-time prewar record for deaths from automobile accidents was nearly 40,000 in 1941 Although in actual numbers heart disease and cancer are the primary killers, Dickinson and Welker<sup>3</sup> question the adequacy of numbers of deaths as the sole measure of the relative importance of the various causes Two new measurements are suggested "life years lost" and "working years lost" When the latter was applied to the seven leading causes of death in four five-year periods, 1930 to 1945, accident, as a destroyer of working years, was third in 1930, second in 1935 and first in 1940 In 1945, during gas rationing, the working years lost from accidental death numbered 1,750,000, whereas those from heart disease were 1,680,000 The young white man, representing the productive strength of the country, was the

special victim It is not implied that all, but only that too many, accidental deaths are due to the automobile One hundred million cars, trucks and busses, and 40 more per minute! This significant milestone in the production line is also a marker on the broad way that leads to destruction

Free enterprise and fierce competition within the industry, the committee believes, is responsible for this triumph of mass production It is suggested, on the other hand, that the achievement marks a point on the errant road of reason Since that fall day in 1793 when a popular actress was crowned goddess of reason in Notre Dame—and in spite of the bad consciences of Robespierre and others—the modern world has believed in and depended upon reason alone In those early days revolutionary reason was most concerned with ends The ends were utopian truth, justice and enlightened self-interest would bring automatic harmony between individuals and society in nature As absolutism and authoritarianism were crushed, new creative activity was released, bringing rapid advances in politics, economics, education and technics With apparently complete success of republicanism and industrialism in the nineteenth century, revolutionary reason or the reason of ends was sacrificed to technical reason or the reason of means This technical reason has produced the present large-scale, industrial, competitive, mass-producing economy rising above physical nature and man himself and its heretical counterpart the totalitarian state with its "planning reason"<sup>4</sup> The hundred millionth motor vehicle is the crown of technical knowledge

This apogee of the assembly line, it is agreed, is a milestone of some sort Yet 40,000 deaths a year is only a pace on the way of man against himself, since the atom bomb can do twice or three times as well in the twinkling of an eye This record production of automobiles is a signal achievement on the road of technical reason, but this road remains the blind alley of men's hope Nevertheless, whatever road it is, the automobile industry should be joined in their self-congratulation on their milestone Let the public-relations counsel tot up the blessings of industrial culture at this season! One looks hopefully for a release from someone about a milestone,

however insignificant, on the straight and narrow path that leads to peace and good will among men

## HANDKERCHIEFS AND THE TRANSFER OF RESPIRATORY INFECTIONS

"Don't put a cold in your pocket" is a slogan used by manufacturers of disposable tissues and designed to sell the public on the idea of substituting their product for the traditional handkerchief. The use of the latter, however, has long been thought to be an effective means of protecting others from infections. A sneeze or cough not protected by a handkerchief has been considered by many as tantamount to a direct assault on the health of one's neighbors—a sort of peacetime version of bacterial warfare. Some recent considerations of the possible role of the handkerchief in the spread of respiratory infections may provide further ammunition for the sales talks against the handkerchief although they offer little solace when it comes to the virtues of the tissues.

In one of the latest studies to be reported in this connection,<sup>1</sup> an estimate was made of the number of bacteria-carrying particles that can be shaken into the air from the handkerchiefs of people with and without nasal discharge. The average number of such particles in a series of 211 handkerchiefs was about 130,000. The particles were large enough to suggest that they each carried a number of bacteria. The predominant organism recovered was *Staphylococcus aureus* and corresponded with those found in cultures of nasal swabs or of the skin of the same subjects. In some cases nonhemolytic streptococci similar to those of the throat and mouth flora were found.

This study was carried out at the Harvard Hospital in England, where investigations are being conducted on the transmission of the common cold. Interestingly enough, there was but small difference between the average counts of infected particles shaken from the handkerchiefs of persons without

nasal discharge and the counts of those with nasal discharge that was either slight, profuse or even purulent.

Because of the recent great interest in aerial disinfectants, studies were made of the effects of some of these agents on the bacteria shed from the handkerchiefs into the air. The infectious particles were found to be resistant to the action of several of the more potent of these aerial disinfectants, including ultraviolet rays and triethylene glycol, employed in the usual concentrations and at normal relative humidities.

Hamburger and Green<sup>2</sup> had previously called attention to the problem of the dangerous carriers of hemolytic streptococci when they found that large numbers of these bacteria could be recovered from the hands of nasal carriers. Hamburger<sup>3</sup> subsequently reported that literally hundreds of thousands of virulent hemolytic streptococci could frequently be recovered from the hands of such carriers. Furthermore, several hundred to almost 50,000 of these pathogens could be transferred to the hands of a noncarrier by an ordinary handshake. The greatest numbers were transferred by carriers who had just blown their noses into sterile handkerchiefs.

Although these experiments were not repeated with materials other than handkerchiefs, it is quite certain that the results would not have been very different had the subjects blown their noses into the best advertised of tissues and discarded them instead of using sterile handkerchiefs, which they would then have put into their pockets.

## INFANT INVESTIGATOR

It is hard to realize that Dr Arnold Gesell, after thirty-seven years on the Yale faculty during most of which time he has been director of Yale's famous Clinic of Child Development, has retired—in order to expand his works still further. Some of Dr Gesell's books, of which there are a full two dozen,

have been the vade mecum of the intellectual young mother, determined that she will rear only superior children. All of them, reporting on territory explored largely by their author, have been enlightening texts on infant behavior and books of reference for the pediatrician and the psychologist.

If one lesson only that Dr. Gesell taught were to be selected as his greatest contribution, it would be that each infant is a person, with its own appetites and satisfactions, its own capacities and its own built-in timing mechanism.

Dr. Gesell, now that he has demonstrated to the world all there is at present to know about child behavior (from the age of four months on), will continue his investigations at Yale University in charge of a child vision research project, under a grant from the American Optical Company. Those who have taken to heart the injunction that where there is no vision the people perish will rejoice that this work is to be under such able direction. Dr. Gesell's pupils, disciples and other fans will wish him continued success in his new work. They may perhaps, looking a long way back, be reminded of another investigator in better vision to whom has been given the credit for the invention of spectacles—Roger Bacon, the Dr. Mirabilis of his day.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### CHANGES IN ISOLATION AND QUARANTINE REQUIREMENTS

The Department has recently made a number of changes in the list of reportable diseases and in the isolation and quarantine requirements. These changes will go into effect as soon as a printing of the revised regulations can be obtained and distribution made to boards of health, school departments, hospitals and other agencies.

To inform physicians of these changes, the following brief résumé is included in this column.

Infectious hepatitis has been added to the list of reportable diseases, hookworm disease, lobar pneumonia and suppurative conjunctivitis have been removed from the list.

Hereafter, there will be no differentiation in the handling of immune and nonimmune contacts of communicable diseases.

*Poliomyelitis* The term "poliomyelitis" will be used instead of the former designation, "anterior poliomyelitis." This will change the order of the disease in the list and in the table of isolation and

quarantine requirements. The deletion of the phrase "and thereafter until acute symptoms have subsided" leaves the isolation of the patient as a period of two weeks from the onset of the disease. All restrictions upon contacts, whether adults or children, have been removed. A placard will no longer be required for the disease.

*Chancroid* There will be no restrictions upon contacts of this disease.

*Chicken pox* The period of isolation will be seven days from the appearance of the eruption.

*Diphtheria* The minimum time limit of one week for isolation of the patient has been eliminated. The patient will be isolated until clinical recovery and the obtaining of negative cultures. There will be no restrictions upon adult contacts of diphtheria, but child contacts will be excluded from school for one week after the patient has been hospitalized or until the child has lived away from home for one week.

*Granuloma inguinale* There will be no restrictions upon contacts of patients with this disease.

*Infectious hepatitis* Patients will be isolated for the duration of fever. There will be no restrictions upon contacts.

*Leprosy* There will be no isolation of patients with leprosy.

*Lymphogranuloma venereum* There will be no restrictions upon contacts of patients with this disease.

*Meningitis, meningococcal* Patients will be isolated for only three days from the beginning of adequate sulfonamide therapy. There will be no restrictions upon contacts.

*Meningitis, other forms* No isolation will be imposed upon cases of meningitis due to organisms other than the meningococcus.

*Mumps* The patient with mumps will be isolated for a week from the onset of the disease, the reference to swelling of the salivary glands being eliminated from the regulations.

*Ophthalmia neonatorum* Infants with infected eyes will be isolated only until two negative smears or cultures to rule out gonococcal ophthalmia have been obtained.

*Salmonellosis* All paratyphoid infections will be included under this designation.

*Plague* The new regulations place restrictions upon contacts of patients with plague only in pneumonic cases, in which the contacts are quarantined for seven days after the last exposure.

*Scarlet fever* Isolation of both adults and children has been reduced to one week from appearance of the rash, and thereafter until clinically recovered, and until purulent discharges, if any, have ceased. Children may be allowed to go to school within one week after patient has been under adequate treatment, or the patient has been hospitalized.

*Whooping cough* There will be no restrictions upon contacts of patients with whooping cough.

## CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The January schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Salem	January 3	Paul W. Hugenberger
Haverhill	January 5	William T. Green
Lowell	January 7	Albert H. Brewster
Greenfield	January 10	Charles L. Sturdevant
Gardner	January 11	Carter R. Rowe
Brockton	January 13	George W. Van Gorder
Springfield	January 18	Garry deN. Hough, Jr.
Pittsfield	January 19	Frank A. Slowick
Hvannis	January 20	Paul L. Norton
Worcester	January 21	John W. O'Meara
Fall River	January 24	David S. Grice

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

## CORRESPONDENCE

### A CORRECTION

To the Editor: In an excellent review of the book *Hodgkin's Disease and Allied Diseases* by Parker and Jackson in the December 2 issue of the *Journal* there are two factual errors. The review is clearly written by a man of experience and knowledge so that these errors may easily have slipped into the preparation of the manuscript. Nevertheless, I believe that they should be corrected. In the review it is stated that we suggest dropping the term endothelioma, which was not intended. We do require a complete autopsy before such a diagnosis is made, for endothelioma, frequent in Java, may very closely simulate undifferentiated carcinoma and unless this condition can be ruled out we believe a diagnosis of endothelioma is unwise. Secondly, the reviewer, though twice using the term giant-follicle lymphoma, once refers to giant-follicle lymphosarcoma. In our opinion "giant-follicle lymphosarcoma" does not and, indeed, cannot exist, even though practically all students of the subject agree that giant-follicle lymphoma frequently progresses, with the passage of time, into lymphosarcoma. The diagnosis, treatment and prognosis is then that of the latter condition — lymphosarcoma.

HENRY JACKSON, JR., M.D.

Mallory Institute of Pathology  
Boston City Hospital

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*History of the Medical Society of the District of Columbia. Part II, 1833-1944.* History Committee. John Benjamin Nichols, chairman, William Johnston Mallory and Joseph Stiles Wall, eds., cloth, 357 pp., with 13 illustrations and frontispiece. Baltimore: Waverly Press, Incorporated, 1947.

This second volume of the history of the Society continues the narrative to approximately July 1, 1944. All the activities of the Society are covered, and a list of members from 1833 to 1911 is appended to the text. Two indexes with subjects and personal names conclude the volume. The book is well published and is recommended for history of medicine collections.

*Gardiner's Handbook of Skin Diseases.* Revised by John Kinnear, O.B.E., T.D., M.D., M.R.C.P. (Ed.), D.L., lecturer in diseases of the skin, St. Andrews University, physician for diseases of the skin, Dundee Royal Infirmary, and derma-

tologist, pre-school and school medical services, Dundee. Fifth edition, 12° cloth, 250 pp. with 80 illustrations and colored plates. Baltimore: The Williams and Wilkins Company, 1948. \$4.50.

This fifth edition of a popular manual, first printed in 1919, has been revised to bring it up to date since the printing of the third edition in 1939. The text was printed in Great Britain and bound in the United States. The volume reflects the British aspect of dermatology.

*The Year Book of Pathology and Clinical Pathology.* "Pathology," editor, Howard T. Karsner, M.D., professor of pathology, director of the Institute of Pathology, Western Reserve University, Cleveland, assistant editor, Herbert Z. Lund, M.D., assistant professor of pathology, Western Reserve University, Cleveland. "Clinical Pathology," editor, Arthur H. Sanford, M.D., professor of clinical pathology, University of Minnesota (The Mayo Foundation), and senior consultant, Division of Clinical Laboratories, Mayo Clinic. 12°, cloth, 558 pp., with 102 illustrations. Chicago: The Year Book Publishers, Incorporated, 1948. \$3.75.

*The Year Book of Pathology* ceased publication in 1941 because of war and post-war conditions. It has now been resumed, and the present volume abstracts the literature for the year 1947. The volume is well published and is recommended for all medical libraries and to persons interested in the subject.

*Ophthalmology in the War Years.* Edited by Meyer Wiener, M.D., professor of clinical ophthalmology, Washington University School of Medicine, and honorary consultant in ophthalmology, Bureau of Medicine and Surgery, United States Navy. Volume II (1944-June, 1946). 8°, cloth, 997 pp. Chicago: The Year Book Publishers, Incorporated, 1948. \$16.00.

This second volume attempts to include in the reviews everything of importance published during the period of two and a half years from 1944 to June, 1946. Thirty-seven persons have contributed to the volume. A few chapters not in the first volume have been added to make the work complete and up to date. Articles not discussed in the reviews have been listed in the bibliographies appended to the chapters. Comprehensive indexes of subjects and authors conclude the volume. The type and paper are good, and the printing excellent. The work is recommended for all medical libraries and ophthalmologists.

*Essentials of Fevers.* By Gerald E. Breen, M.D., B.Ch. (NUI Dub.), D.P.H., D.O.M.S. (R.C.P. Lond., R.C.S. Eng.). Second edition, 16°, cloth, 351 pp., with 23 illustrations and 17 plates. Baltimore: The Williams and Wilkins Company, 1948. \$4.50.

This second edition of a manual, first published in 1939, has been revised to include new sections on typhus glandular and undulant fevers, influenza and encephalitis lethargica. Additions have been made to the chapters on sore throat and food poisoning. The article on dysentery has been rewritten and expanded. Color plates have been included for the first time. The type, printing and paper are good (the book was printed in Great Britain). The manual should prove useful as a reference source for the general practitioner.

*Conference on Metabolic Aspects of Corroscence.* Transactions of the fifteenth meeting. Edited by Edward C. Reifstein, Jr., M.D., 8°, paper, 163 pp., with 35 illustrations. New York: Josiah Macy, Jr. Foundation, 1947. \$2.25.

This conference was featured by a symposium on the isotopes with fourteen persons participating. Eighteen other persons contributed discussions on various aspects of metabolism. The different conferences of the Macy Foundation should be in all medical libraries.

## NOTICES

JOSEPH H PRATT  
DIAGNOSTIC HOSPITAL

30 Bennet Street, Boston  
Lecture Hall, 9-10 a m

## MEDICAL CONFERENCE PROGRAM

Tuesday, January 4 — Vitamin B<sub>12</sub> Therapy in Pernicious Anemia Dr Abraham Frumin

Friday, January 7 — Carcinoma of the Cervix Dr Howard Ulfelder

Wednesday, January 12 — Pediatric Clinicopathological Conference Drs James M Baty and H E MacMahon

Friday, January 14 — Differential Spinal Block Dr Stanley J Sarnoff

Tuesday, January 18 — *Journal* review

Friday, January 21 — Simplified Blood Sugar Screening Method Dr Hugh L C Wilkerson

Tuesday, January 25 — The Clinical Use of Washed Red Cell Transfusions Dr Jacob Neber

Friday, January 28 — The Use of Tests that Measure Hepatic Excretory Functions Dr Albert I Mendeloff

On Tuesday morning, January 11, from 9 to 10 o'clock and on Wednesday mornings, January 5, 19 and 26, from 9 to 10 o'clock, Dr S J Thannhauser will give medical clinics on hospital cases. On Thursday mornings from 9 to 10 o'clock clinics will be given by Dr William Dameshek.

On the second and fourth Fridays of the month, January 14 and 28, therapeutic conferences will be held with round-table discussion from 2 to 4 o'clock (Dr Robert P McCombs, moderator). On the second and fourth Fridays, January 14 and 28, Dr Merrill Sosman will conduct x-ray conferences from 4 to 6 o'clock. On Saturday mornings from 9 to 10 o'clock surgical clinics will be given by Dr C Stuart Welch. Medical rounds are conducted each weekday except Saturday by members of the hospital staff from 12 to 1 o'clock.

All exercises are open to the medical profession

NEW ENGLAND HOSPITAL FOR  
WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, January 6, at 7 15 p m in the classroom of the Nurses' Residence. Dr Cleveland Floyd will speak on the subject "Miliary Tuberculosis." Dr Pauline Luzackas will be chairman.

## NEW ENGLAND HEART ASSOCIATION

A meeting of the New England Heart Association will be held in the amphitheater of the Dowling Building, Boston City Hospital, on Monday, January 10, at 8 15 p m, Dr Laurence B Ellis presiding.

## PROGRAM

Functional Renal Insufficiency Precipitated in Patients with Congestive Failure by Sodium Depletion Drs Frank Drinan and Kermit H Katz

Mitral Stenosis, with Special Reference to Surgical Intervention

Clinical-Physiologic Correlations Drs Laurence B Ellis, J G Mebane, George Maresh, W K Long, and R A Bloomfield

Experimental Studies on Mitral-Valve Function Dr Leona R Norman

Surgical Aspects Dr Dwight E Harken

Thrombosis in Arteriosclerosis of the Lower Extremities Dr Edward A Edwards

Interested physicians and medical students are cordially invited to attend

NEW ENGLAND SOCIETY OF  
ANESTHESIOLOGISTS

A meeting of the New England Society of Anesthesiologists will be held in the Auditorium of Building A, Boston University School of Medicine, 80 East Concord Street, Boston, on Tuesday, January 11, at 8 00 p m. The scientific program will consist of the following:

Changes in Body Fluid Chemistry as They Affect Pre-operative and Postoperative Care Francis D Moore, M D

The Clinical Aspects of Pulmonary Atelectasis Cutting B Favour, M D

Pathologic Aspects of Postoperative Pulmonary Atelectasis Joseph D Boggs, M D

Aspiration Bronchoscopy in the Treatment of Post-operative Pulmonary Atelectasis William S Derrick, M D

Physicians and medical students are invited

## HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society will be held in the amphitheater of Building D, Harvard Medical School, on Tuesday, January 11 at 8 00 p m. The chairman for the evening is Dr Raymond D Adams.

## PROGRAM

The Correlation between Morphologic and Functional Disorders in the Motor-Nerve Cells in Poliomyelitis Derek E Denny-Brown and Joseph M Foley

An Encephalomyelitic Virus of Mice Causing Demyelinating Lesions of the Central Nervous System F Sargent Cheever, O T Bailey and A M Pappenheimer

Pathological Changes in Carbon Monoxide Poisoning Charles S Kubik

Subsequent meetings will be held on February 8, March 8, April 12 and May 10

## SUFFOLK DISTRICT MEDICAL SOCIETY

The third medicolegal meeting of the Suffolk District Medical Society and the Boston Bar Association will be held in Ware Hall, Boston Medical Library, on Wednesday, January 12, at 8 p m. Dr Alan R Moritz will speak on the subject "Scientific and Medical Tests in Legal Proceedings," which will be discussed by Mr Arthur F Bickford, prominent Boston trial lawyer.

## NEW ENGLAND PEDIATRIC SOCIETY

The annual meeting of the New England Pediatric Society will be held on Wednesday, January 26.

After the business meeting of the evening, Dr Bronson Crothers will speak on the subject, "The Position of the Pediatrician in Relation to Specialists of Various Categories, Present and Impending."

Further details concerning the meeting will be forthcoming at a later date.

UNIVERSITY OF WISCONSIN SYMPOSIUM ON  
SCIENCE AND CIVILIZATION

As part of the general celebration of the centennial anniversary of the University of Wisconsin, the University's History of Science Group is sponsoring a symposium on "Science and Civilization." This symposium will be held January 13-15 at the Memorial Union of the University of Wisconsin in Madison.

## MISSISSIPPI VALLEY MEDICAL SOCIETY

The annual meeting of the Mississippi Valley Medical Society will be held at the Jefferson Hotel, St. Louis, Missouri, from September 28 to 30, under the presidency of Dr Alphonse McMahon, of St. Louis University.

(Notices concluded on page vii)

## NOTICES (Concluded from page 1060)

## AMERICAN MEDICAL ASSOCIATION COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The forty-ninth annual congress on medical education and licensure will be held in the Red Lacquer Room, Palmer House, Chicago, on February 7 and 8. The fourth annual conference on rural health (sponsored by the Committee on Rural Health of the American Medical Association), will be held in the Red Lacquer Room, Palmer House, Chicago on February 4 and 5 from 9 30 a m to 5 00 p m. On February 6 the Advisory Board for Medical Specialties will hold an open meeting in the Crystal Room, Palmer House, Chicago (time to be announced later). From 9 30 a m to 5 00 p m the National Conference on Medical Service, sponsored by officers of state medical societies, will be held in the Red Lacquer Room, Palmer House, Chicago.

## MISSISSIPPI VALLEY MEDICAL SOCIETY 1949 ESSAY CONTEST

The Ninth Annual Essay Contest of the Mississippi Valley Medical Society will be held in 1949. The society will offer a cash prize of \$100.00, a gold medal, and a certificate of award for the best unpublished essay on any subject of general medical interest (including medical economics and education) and practical value to the general practitioner of medicine. Certificates of merit may also be granted to the physicians whose essays are rated second and third best. Contestants must be members of the American Medical Association who are residents and citizens of the United States. The winner will be invited to present his contribution before the Fourteenth Annual Meeting of the Mississippi Valley Medical Society to be held in St. Louis, Missouri, September 28, 29 and 30, 1949, the society reserving the exclusive right to first publish the essay in its official publication—the *Mississippi Valley Medical Journal* (incorporating the *Radiologic Review*). All contributions shall be typewritten in English in manuscript form, submitted in five copies, not to exceed 5000 words, and must be received not later than May 1, 1949. The winning essays in the 1948 contest appear in the January 1949 issue of the *Mississippi Valley Medical Journal*. Further details may be obtained from Harold Swanberg, M.D., Secretary, Mississippi Valley Medical Society, 209-224 W C U Building, Quincy, Illinois.

## Old Way...

### CURING RICKETS in the CLEFT of an ASH TREE

FOR many centuries,—and apparently down to the present time, even in this country—ricketic children have been passed through a cleft ash tree to cure them of their rickets, and thenceforth a sympathetic relationship was supposed to exist between them and the tree.

Frazer\* states that the ordinary mode of effecting the cure is to split a young ash sapling longitudinally for a few feet and pass the child, naked, either three times or three times three through the fissure at sunrise. In the West of England, it is said the passage must be "against the sun." As soon as the ceremony is performed, the tree is bound tightly up and the fissure plastered over with mud or clay. The belief is that just as the cleft in the tree will be healed, so the child's body will be healed, but that if the rift in the tree remains open, the deformity in the child will remain, too, and if the tree were to die, the death of the child would surely follow.

\*Frazer, J. G.: *The Golden Bough*, vol. 1, New York, Macmillan & Co., 1923.

It is ironical that the practice of attempting to cure rickets by holding the child in the cleft of an ash tree was associated with the rising of the sun, the light of which we now know is in itself one of Nature's specifics.

### Preventing and Curing Rickets with OLEUM PERCOMORPHUM

NOWADAYS, the physician has at his command, Mead's Oleum Percomorphum, a Council-Accepted vitamin D product which actually prevents and cures rickets, when given in proper dosage.

Like other specifics for other diseases, larger dosage may be required for extreme cases. It is safe to say that when used in the indicated dosage, Mead's Oleum Percomorphum is a specific in almost all cases of rickets, regardless of

degree and duration. Mead's Oleum Percomorphum because of its high vitamins A and D content is also useful in deficiency conditions such as tetany, osteomalacia and xerophthalmia.

\* \* \*

#### COUNCIL-ACCEPTED

Oleum Percomorphum With Other Fish Liver Oils and Viosterol. Contains 60,000 vitamin A units and 8,500 vitamin D units per gram and is supplied in 10 c.c. and 50 c.c. bottles; and in bottles containing 50 and 250 capsules.
